SYMPTOMATICAL, in medicine, is a term often used to denote the difference between the primary and secondary causes in diseases. — As a fever from pain is said to be symptomatical, because it rises from pain only, and therefore the ordinary means in fevers are not in such cases to be had recourse to, but to what will remove the pain; for, when that ceases, the fever will cease without any direct means taken for it.

SYNÆRESIS, *συναίρεσις*, contraction in grammar, a figure whereby two syllables are united in one; as *vehemens* for *vehemens*.

SYNAGOGUE, *συναγωγή*, a particular assembly of Jews met to perform the offices of their religion. Also the place wherein they meet.

SYNALOEPHA, *συναλοιφή*, in grammar, a contraction of syllables, performed principally by suppressing some vowel or diphthong at the end of a word, on account of another vowel or diphthong at the beginning of the next. As *ill' ego*, for *ille ego*, &c.

SYNARTHROSIS, in anatomy, a species of articulation, wherein there is only an obscure motion, as in the bones of the carpus and metacarpus, the tarsus and metatarsus, &c. or there is no motion at all, as in the sutures of the skull, and articulation per harmoniam or bare application.

SYNCHONDROSIS, in anatomy, a species of symphysis, being the union of two bones by means of a cartilage, as in the vertebrae.

SYNCOPATION, in music, denotes a striking or beating of time, whereby the distinction of the several times or parts of the measure is interrupted.

However, it is more properly used for the connecting the last note of any measure, or bar, with the first of the following measure; so as only to make one note of both.

A syncope is sometimes also made in the middle of a measure.

Syncopation is also used when a note of one part ends or terminates on the middle of a note of the other part. This is otherwise denominated binding.

It is likewise used for a driving note; that is, when some shorter note at the beginning of a measure, or half measure, is followed by two, three, or more longer notes before another short note occurs, equal to that which occasioned the driving, to make the number even, e. gr. when an odd crotchet comes before two or three minims, or an odd quaver before two, three, or more crotchets.

In syncopated or driving notes, the hand or foot is taken up, or put down, while the note is sounding.

SYNCOPE, is a sudden retardation or stoppage of the circulation of the blood.

It may proceed from a natural weakness, any violent passions, as surprise, fear, joy, &c. sudden and large evacuations, as hæmorrhages, hypercatharses profuse sweating, &c. breathing in an air too thin, or hot; hunger, loss of appetite, &c.

It is known by a clammy sweat on the face, less of colour in the lips, a tremor, dulness, and fixedness of the eyes; only their white sometimes appearing; a small languid pulse; but in the very fit none at all is perceivable; and sense and motion appear to be lost.

When this case proceeds from the large evacuations, passions of the mind, natural weakness, breathing in an air too hot, or too much rarified, it is often fatal. Happening without any evident cause, it is reputed dangerous; frequent relapses are also supposed dangerous, unless they be hysterical.

In the fit apply volatile salts, &c. to the nose, dip the hands in cold water, or sprinkle it on the face; burn brown paper under the nose, &c.

If it proceeds from a furious passion, and the patient be plethoric, bleed directly, and apply a blister, for fear the case should grow convulsive or epileptic; and give a strong, narcotic and repeat it pro re nata. But in depressed passions omit narcotics, and give wine, &c. and endeavour to make the patient cheerful.

An emetic epispastic and the cold bath are proper for both kinds. In short, proceed here as in the different species of madness, into which these cases often degenerate.

If the cause was a violent diarrhæa, first put a stop to that, and then give a strong cardiac or opiate.

If from an hæmorrhage, and this does not cease during the fit, use phlebotomy by way of revulsion, or give and repeat an opiate occasionally; allow the patient to drink claret and water, corroborating jellies or broths, and let all manner of exercise and heat be avoided.

If the disorder proceed from sweating, through a laxity of pores, use the cold bath out of the fit.

If from artificial sweating, let the patient cool gradually, by changing his place in the bed; and what he drinks should not be made too warm.

When from mephitical exhalations, immediately expose the patient to the cool air; and, if this succeeds not, bleed him, or throw him into cold water.

When it proceeds from heat, or the air too much rarified, remove the person into an air that is colder and denser; but when it is symptomatical, regard must be had to the original disease.

To prevent its happening from phlebotomy, let the patient bleed in a horizontal posture, or lying on the bed.

SYNCOPE, in grammar, denotes an elision or retrenchment of one or more letters or syllables from a word.

As when we say *virum* for *virorum*, and *manet altamentum* for *repositum*.

SYNDIC, in government and commerce, an officer in divers countries, intrusted with the affairs of a city or other community; who calls meetings, makes representations and solicitations to the ministry, magistracy, &c. according to the exigency of the case.

The word is formed from the Latin *syndicus*, and that from the Greek, *συνδικος*, which signifies the same.

Syndic is also used for a person appointed to solicit some common affair, wherein he himself has a share; as happens, particularly, among several creditors of the same debtor, who fails or dies insolvent.

SYNDROME, a word introduced into medicine by the empirics, who mean by it a concurrence of symptoms: thus under a plethora an empiric judges venesection necessary from a syndrome of symptoms, such as distension of the vessels, a redness and gravity of the whole body, an indisposition to motion, tensions of the limbs, and a sense of an ulcerous lassitude, besides a life spent in idleness, high and full feeding, and a suppression of wonted excretions. This is the plethoric syndrome of an empiric, and after the same manner he forms a syndrome or concurrence of symptoms in a peripneumony, quinsey, epilepsy, and other diseases. Galen ridicules these syndromes, because, he says, they happen very rarely, and also very slowly; so that should a physician wait for a syndrome of all the symptoms he expects, he might administer his remedies to late.

SYNECDOCHE, in rhetoric, a kind of figure, or rather trope frequent among orators and poets.

The word is Greek, formed of *συνεκεχειν*, to take together.

There are three kinds of synecdoches; by the first, a part is taken for the whole; as the point for the sword, the roof for the house, the sails for the ship, &c.

By the second, the whole is used for a part. — By the third, the matter of which the thing is made, is used for the

the thing itself; as steel for sword, silver for money, &c. —To which may be added another kind, where the species is used for the genus, or the genus for the species.

SYNECDOCHE, in Greek and Latin grammar, is when the ablative of a part or an adjunct of a sentence is changed into the accusative, the Greek proposition *κατα*, or the Latin *secundum*, or *quod ad*, being understood. Examples of the ablative of the part being changed into the accusative, are the following from Virgil. *Explera mentem nequit*, for *quod ad mentem*; and *Deiphobum videt lacerum crudeliter ora*, for *quod ad ora*; and an example of the ablative of the adjunct being changed into the accusative from the same author, is as follows. *Flores inscripti nomina regum*, for *quod ad nomina regum*.

SYNGENESIA, *συγγενεσία*, in botany, one of Linnaeus's classes of plants, the nineteenth in order; so called because the stamina in these plants grow together, or are formed into a single regular congeries.

The general characters of this class are these: the cup is the crown of the seeds, and stands on the summit of the germen; and the compound flowers are very various, in regard to the nature of the floscules. 1. Some are composed of tubulose hermaphrodite flowers in the disk, and of the same sort of tubulous hermaphrodite flowers in the radius. 2. Others are composed of tubulose hermaphrodite flowers in the disk, and of tubulous female flowers in the radius. 3. Some are composed of tubulous hermaphrodite flowers in the disk, and of tubulose neutral flowers in the radius. 4. Some have tubulose hermaphrodite flowers in the disk, and ligulated hermaphrodite flowers in the radius. 5. Some are composed of tubulous hermaphrodite flowers in the disk, and of ligulated female flowers in the radius. 6. Some are composed of tubulous hermaphrodite flowers in the disk, and ligulated neutral flowers in the radius. 7. Some are composed of tubulous hermaphrodite flowers in the disk, and of naked and neutral flowers in the radius. 8. Some are composed of tubulose male flowers in the disk, and of naked female flowers in the radius. And, 9. Some are composed of ligulated female flowers in the disk, and ligulated hermaphrodite flowers in the radius.

The stamina are five very short and slender filaments, inserted into the tube of the flower. The antheræ are of the same number with the stamina; they are slender, erect, and grow together at their sides, so as to form a tubular cylindric body of the length of the mouth of the flower; and divided into five segments at the edge. The germen of the pistil is oblong, and placed under the receptacle of the flower. The style is capillary erect, and of the length of the stamina, and goes through the cylinder formed by the antheræ. The stigma is divided into two parts, which stand open, and bend backwards.

These plants have properly no pericarpium, though in some few species there is a coriaceous crust placed about the seed. The seed is single and oblong, often of a quadrangular figure, and some times narrower at the base than in any other part. However, in different genera of this class, they are of a very different appearance at the ends. Some are crowned with a downy matter, composed of a great number of single short filaments, placed circularly, or otherwise, on the head of the seed. In some the downy matter is radiated; in others it is ramose or branched; and in some it is supported on a pedicle, while in others it stands immediately on the seed. In some genera the seeds have no down at all, but have a small corona, formed of what was originally the cup of the flower. This is permanent, and divided usually into five segments. In some genera the seed is wholly naked, having neither any down nor this crown of a cup.

SYNNEUROSIS, in anatomy, a kind of articulation of the bones, performed by the intervention of ligaments. See **ARTICULATION**.

The synneurosis is reckoned a branch of the symphyfis, and is, when the bones are connected together by a ligament, as in the os femoris to the os ischium, and the patella to the tibia.

SYNOCHUS, in medicine, a continual fever without any remission. See **FEVER**.

SYNOD, in astronomy, a conjunction, or concurrence of two or more stars, or planets in the same optical place of the heavens.

SYNOD, or *Council*, in Ecclesiastical history, imply a meeting, or assembly of bishops, or governors of the church, to rectify abuses in faith or discipline, to enact laws or canons for the government of the church, and to regulate all matters relating to the state of religion.

Under the article **COUNCIL** we have mentioned some of the most famous that have been held in the Church, and referred the reader to Du Pin's History for a more ample detail; but at the request of several of our subscribers we have added here the following account of these famous assemblies, and hope it will prove agreeable to our readers.

Some of these ecclesiastical assemblies, are provincial, others national, and others oecumenical or general. Provincial synods, or councils, are those in which the bishops of one province only meet: national; those in which the bishops of one nation are assembled; and oecumenical or general, those in which the bishops from all parts of the Christian world are assembled.

It was part of the office of the metropolitan bishops, in the antient church, to call provincial synods, and preside in them. And this they did by circular letters, called *synodica* and *tractoria*, which no bishop of the province might disobey under pain of suspension, or some such canonical censure, at the discretion of the metropolitan and the council. The canons appointed, that two such synods should be held yearly in each province, besides such as might be called upon extraordinary occasions. And one reason assigned for it is this; that if any clergyman chanced to be unjustly censured by the passion of his bishop, he might have recourse to a superior court, and there have justice done him.

Every bishop had, at first, the privilege of ordering the affairs of his own diocese, independently of all other bishops. But when the world became divided into several kingdoms, it was found necessary, that all the churches of such or such a nation should, for the sake of unity, and to avoid confusion, observe the same customs and usages. Hence national synods or councils were instituted, whose decrees were obligatory on all the churches of particular nations or kingdoms. And the same may be observed with respect to general or oecumenical councils, in which bishops assembled from all parts of the world to consult about such matters as related to the good of the universal church.

The first synod we read of, is that held by the apostles themselves at Jerusalem, to deliberate whether the ceremonies of the Mosaic law were to be observed. These assemblies were more rare in the three first centuries, and not so famous as in the following ages, as well because the persecutions of the Pagan emperors hindered the bishops from assembling freely and publicly, as because, the traditions of the apostles being yet new, it was not necessary to assemble councils, to establish the truth and condemn error. In after ages, councils were very frequent, both on account of the necessity of establishing discipline in the Christian churches, which multiplied daily in all parts of the world, as also to condemn, and put a stop to, the numberless heresies, that were perpetually springing up, and disturbing the peace of the church. Some councils were held by the heretics themselves, where their power and influence were strong enough.

The First General Synod or Council of Nice, A. D. 325.

This council was held at Nice, in Bithynia. It was the emperor Constantine that called it, and it was composed of 318 bishops. The legates of pope Sylvester assisted at it. It is not certainly known who was president of this assembly; but 'tis probable it was Hosius bishop of Corduba.

This council drew up a creed, in which it declared, that the Son of God was consubstantial with his Father: and anathematized all such as should say, there was a time when the Son of God did not exist, that he was created out of nothing, that he is of a different substance from his Father, and that he is liable to change. It condemned

demned Arius, who held that doctrine, with the bishops Secundus and Theonas. It made a decree, that Easter should be celebrated in all churches, on the Sunday after the fourteenth day of the moon of March; and drew up twenty canons about discipline. The emperor published the decisions of this council to all the world, and the bishops directed a letter particularly to the Christians in Egypt, to inform them of what they had ordained, with relation to the Arians, and the feast of Easter.

The decisions of the council of Nice were received by all the Churches, and no bishops opposed them at first, excepting Secundus and Theonas, who were sent into exile. But some time after, the partisans of Arius endeavoured to overthrow the doctrine of the Council, by calling assemblies, in which they deposed its chief defenders, and published other different confessions of faith. In 330 they held one at Antioch, in which Eustathius bishop of Antioch, who had been one of the chief prelates of the council of Nice, was deposed. St. Athanasius, who was ordained bishop of Alexandria after the death of Alexander, one of the most zealous adversaries of Arius, was cited to the council of Cæsarea in 333, and deposed in that of Tyre in 335. Marcellus of Ancyra, who wrote against the Arians, was condemned in 336, in the council of Constantinople. Paul, bishop of that city, was deposed in another synod in 338. In the councils held at Antioch in 341, 342, and 344, the Eusebians drew up new articles of faith, different from those of the Council of Nice. On the other side, St. Athanasius was declared innocent in a council held at Alexandria in 340, and by a council, which Pope Julius held at Rome in 341. The bishops of the West subscribed to the Nicene confession in a council, assembled at Milan in 346.

The First General Synod, or Council of Constantinople, A. D. 381.

This council was held in the beginning of the reign of Theodosius. It was made up of bishops from all parts of the Eastern Empire, except Egypt. Meletius, bishop of Antioch, presided in it, and established St. Gregory Nazianzen in the see of Constantinople. It was in this synod, probably, that the canon was made against Maximus, who designed to take possession of the see of Constantinople; and that, which granted the second rank to the bishop of Constantinople. Meletius died before the end of this synod.

Flavianus, who succeeded him in the beginning of the year 382, came to Constantinople with the bishops of the East, whither also came the bishops of Egypt. St. Gregory Nazianzen was obliged to renounce the see of Constantinople; and Nectarius was put in his place.

This council also drew up a creed, not very different from that of Nice, only adding to it more precise terms, to express the divinity of the Holy Ghost, who is there called "the quickening Lord, who proceeds from the Father, who ought to be worshipped with the Father and the Son, and who spake by the prophets." They likewise profess to believe "one only holy, catholic, and apostolical church; one only baptism for the remission of sins; the resurrection of the body, and the life of a future state." We have likewise six canons of this council.

The General Synod or Council of Ephesus, A. D.

431.

The emperor Theodosius summoned this council. The time appointed for its meeting drawing near St. Cyril arrived at Ephesus, with fifty bishops from Egypt: Juvenal also came with the bishops of Palestine. But John of Antioch excused himself upon account of the distance, and wrote to St. Cyril, that he would come in five or six days time. The emperor sent the count Candidianus, to maintain the safety and tranquillity of the council. Fifteen days after the calling of the council, St. Cyril, Juvenal, and the bishops of Egypt and Asia, assembled in the great church of St. Mary, the 22d of June, altho' the legates of the holy see were not arrived.

The president of this council was St. Cyril: but some pretend it was in the name of the pope. It is certain Celestin commissioned him to execute the judgment passed against Nestorius: but we have no ground to suppose, that he gave him charge to preside in his name at the

council of Ephesus; on the contrary, he sent legates thither to represent himself: St. Cyril however takes the title of Celestin's representative, in the subscriptions.

The number of bishops at this council was almost 200, according to the testimony of the council itself; the subscriptions give us a list of 160; altho' the eastern bishops do not reckon above fifty from Egypt, thirty from Asia, and some others.

The day appointed for holding the council, as also that which John of Antioch, and the eastern bishops, had prefixed for their meeting, being passed, the bishops assembled. The count Candidianus proposed, that they should wait for the eastern bishops, who were shortly to arrive; but Memnon bishop of Ephesus remonstrating, that they had waited for them sixteen days, St. Cyril, and the other bishops, proceeded, in the absence of Candidianus, who withdrew. Nestorius was cited thrice; but he answered, he would not appear till the eastern bishops were come. The bishops, after having recited the Nicene Creed, and heard the extracts of his writings, and the testimonies, by which he was convicted of having taught, that Mary was not the mother of God, and that he who was man, and had suffered in the person of Jesus Christ, was a different person from God, declared him degraded from the episcopal dignity, and separated from the sacerdotal communion. The next day, this sentence was signified to Nestorius, and the council wrote to the emperor, and the clergy of Constantinople, what had passed.

The General Synod, or Council of Chalcedon, A. D. 451.

This council was held in the great church of St. Euphemia, in the presence of the commissioners, officers of the Emperor Martianus, and counsellors of state, who regulated every motion of it, and were seated in the middle of the assembly. At their left were Paschasius and Lucentius, bishops, and the priest Boniface, the Pope's Legates; then Anatolus of Constantinople, and after him Maximus of Antioch, and the bishops of the East. On the right was Dioscorus of Alexandria, Juvenal of Jerusalem, and the bishops of Egypt, Illyria, and Palestine. The holy Gospels were placed in the middle. The number of the bishops was about 600. However, there are but 350 in the subscriptions.

Dioscorus, and Eusebius of Doryleum, appeared there as parties. Eusebius accused Dioscorus. Theodoret presented himself in order to be admitted; but the bishops of Egypt and Illyria opposed it. The commissioners ordered, that he should enter as an accuser. The acts of the council of Dioscorus were read; upon which it was declared, That Flavianus, and Eusebius of Doryleum, had been unjustly condemned in that council, and that the bishops, who had condemned them, deserved to be deposed. In the second session, they treated of matters of faith; the result whereof was, the approbation of the letter of St. Leo to Flavianus, wherein the error of Eutychius was condemned. Dioscorus, being cited, in the third session, and refusing to appear, was deposed. In the fourth, they received Juvenal of Jerusalem, Thalassius of Cæsarea, and the other bishops, who repented of having signed the judgment given against Flavianus, and who condemned Dioscorus and Eutychius. There was a particular meeting held upon the difference between Eustathius of Berytes, and Photius of Tyre, for the right of the metropolis. Photius gained the cause, and remained sole Metropolitan, notwithstanding the civil division of the province, which the emperor had made. It was likewise decreed, that for the future the letters, which the cities should obtain of the Emperor, to be erected into Metropolies, should not prejudice the ancient Ecclesiastical Metropolies.

In the fifth session, they drew up, and approved, a confession of faith, in which it is declared, That we must believe in one only Jesus Christ our Lord, the Son of God, perfect in his divinity, and in his humanity, consubstantial with God according to his divinity, and with men according to his humanity; who has two united natures, without change, division, or separation; so that the properties of the two natures subsist and agree in one and the same person; which is not divided into two, but is one only Jesus Christ, the Son of God.

Q q q

The

The emperor assisted in person at the sixth meeting, held on the twenty-fifth of November; at which time the confession of faith was read over again, and approved, and signed by all the bishops.

The Second General Synod, or Council of Constantinople, A. D. 553.

The dispute about the three chapters is one of those, which was debated with the greatest heat of any in the VIth Century. The origin and progress of it was briefly this.

Pelagius, surrogate of the church of Rome, residing in the East, in hatred to Theodorus bishop of Cæsarea, got Origen to be condemned by an edict of the emperor Justinian, in the year 541. Mennas, patriarch of Constantinople, and the other bishops, approved and received that judgment. Theodorus was of the sect of the Acephali, or Eutychians, who did not receive the determination of the council of Chalcedon. The empress Theodora favoured that sect; but Justinian, who owned the authority of the council of Chalcedon, resolved to condemn it. Theodora, to ward off that blow, and to be revenged for the condemnation of Origen, represented to the emperor, that it was needless to publish any edict against the Acephali, who would all re-unite, and approve the council of Chalcedon, if Theodorus of Mopsuestia and his writings were anathematized, the writings of Theodoret against St. Cyril condemned, as also the letter of Ibas bishop of Edessa, which had been read in the council of Chalcedon. The emperor, imagining he should do a great benefit to the church, in procuring the re-union of several persons, by the condemnation of three dead authors, whose reputation was doubtful, published an edict, condemning the three writings above-mentioned; which afterwards became so famous under the name of the three chapters. This edict was published towards the end of the year 545. And to add a greater authority to this condemnation, the emperor caused a council to be assembled at Constantinople in 546, which condemned the person and writings of Theodorus bishop of Mopsuestia, the writings of Theodoret against the twelve articles of St. Cyril, and Ibas's letter.

The Third General Synod, or Council of Constantinople, A. D. 680.

This council of Constantinople began in the thirteenth year of the emperor Constantine Pogonatus, and was concluded in eighteen sessions. The emperor held the first place in it, and assisted in person at the first eleven meetings, and at the last. He was attended with consuls and officers. The Patriarchs of Constantinople and Antioch assisted in person; those of Rome, Alexandria, and Jerusalem, by deputies; and all the western bishops, by three deputies from the council of Rome, with several eastern bishops, whose number increased as they came to Constantinople: for at first there were only between thirty and forty present; but at last they amounted to above 160.

This was the order observed amongst the patriarchs of this council. The pope's legates held the first rank; George, patriarch of Constantinople, the second; a deputy from the church of Alexandria the third; Macarius, patriarch of Antioch, the fourth; the patriarch of Jerusalem the fifth; and the deputies from the council of Rome the sixth: after these were the deputies of the church of Ravenna, and then the bishops and abbots.

At the first meeting, the pope's legates accused the patriarchs of Constantinople and Antioch of having invented and maintained novelties, teaching, that there was but one will in Jesus Christ. Macarius, patriarch of Antioch, undertook their defence. The acts of the councils were ordered to be read; and in this session they read those of the council of Ephesus; in the following, those of the council of Chalcedon; and in the third, held the thirteenth of November, those of the fifth general council. At the fourth meeting, they read the letters of pope Agathon, and those of the council of Rome. Macarius produced, at the fifth and sixth meetings, several passages out of the fathers, which he thought favoured his opinion. At the seventh meeting, held the thirteenth of February 681, pope Agathon's deputies presented a collection of other passages out of the

fathers, to prove the doctrine of two wills. At the eighth meeting held the seventh of March, the patriarch of Constantinople, having examined pope Agathon's letter, and the passages out of the fathers, declared he was of the same sentiments with the pope, and the other western bishops. All the bishops of his patriarchate made the like declarations, excepting Theodorus bishop of Melitum, who desired that neither party might be condemned.

Macarius, bishop of Antioch, persisted in his opinion, and strenuously maintained, that there was but one operation, and one will in Jesus Christ. He was heard as a party; and at the ninth meeting, they examined the passages, upon which he founded his opinion. At the following meetings, they continued to examine the writings on both sides, and the authorities, which were alledged.

In fine, at the seventeenth meeting, held the sixteenth of September 681, at which the emperor assisted, they published a decision, by which they approved pope Agathon's letter, and the decision of the council of Rome; importing, that there are two natural wills, and two operations, in Jesus Christ, in one only person, without division, mixture, or change; although those wills are not opposite, but the human will follows the divine, and is entirely subject to it. This decision was approved by all the bishops of the council, who pronounced an anathema against the old and new heretics, and in particular against Honorius, who is always reckoned amongst the Monothelite patriarchs, and comprized in the same condemnation. Macarius bishop of Antioch, and two other bishops, called Stephen and Polychronius, who persisted in their sentiments, were deposed.

The eastern and western churches, that were united in the same faith and communion, approved the decision of the council, and the anathema, which was pronounced against the bishops, who had maintained the contrary error. The emperor published an edict against the Monothelites, which entirely appeased the troubles of the eastern churches.

The Second General Synod, or Council of Nice, A. D. 787.

The emperor Leo Isaurus, resolving to abolish the use and worship of images, which were received in the East, published an edict, in 730, by which he ordered them to be taken out of the churches, and thrown into the fire. His son Constantine Copronymus followed the example of his father; and, the better to establish the discipline he had a mind to introduce, he caused a council to be assembled at Constantinople, in 754, consisting of 338 bishops, who made a decree against the worship of images. This council was not received in the church of Rome; but the emperor caused the decree to be executed in part of the eastern churches.

When Irene became mistress of the empire, she resolved to assemble a new council, to which she invited pope Adrian, who sent thither two priests as his deputies. The council met at Constantinople in 786; but, being disturbed by the officers of the army and the soldiers, who were stirred up by the bishops that opposed the worship of images, it was transferred to Nice in 787. The pope's legates held the first place in it: Tarasus, patriarch of Constantinople, the second; and the deputies of the bishops of the East the third; after them, Agapetus bishop of Cæsarea in Cappadocia, John bishop of Ephesus, Constantine metropolitan of Cyprus, with 250 archbishops and bishops, and above a hundred priests and monks. Two commissioners from the emperor and empress assisted at it.

The first meeting was held the fourteenth of September, in St. Sophia's church. They received the bishops, who, changing their opinion, made profession of honouring images for the future. At the second meeting, held the twenty-eighth of the same month, pope Adrian's letters to the emperor Constantine, and Tarasus patriarch of Constantinople, were read, in which that pope approved the worship of images. Tarasus declared, that he approved the worship of the images of the virgin, of angels and saints, although he adored none but God alone with the sovereign worship of Laetitia, and put his trust in him only. All the bishops made

made the same declarations. At the third meeting, held the twenty-eighth of September, they likewise admitted some bishops, who abjured the decree of the preceding council. They read the synodical letter, which Tarasus had sent to the patriarchs, in which he had added to his confession of faith, about the Trinity and Incarnation, the intercession of saints, of the virgin, of angels, and the worship of their images. They likewise read the letter of Theodosius of Jerusalem, which had been approved by the eastern bishops, wherein the worship of images was likewise maintained. At the fourth meeting, Tarasus caused to be read the testimonies of the scripture, and of the saints, which, he pretended, authorised the worship of images. At the fifth meeting, they continued to produce pieces, to shew, that the Iconoclasts had imitated the antient heretics in breaking down images. The sixth meeting, held the fifth or sixth of October, was employed in reading and refuting the acts of the council of Constantinople, which had condemned the worship and use of images.

The Fifth General Synod or Council of Constantinople, A. D. 869.

In the East, after the death of Methodius, patriarch of Constantinople, Ignatius, son to the emperor Michael Curopalata, who had till then led a monastical life in the isles of Hieres and Terebinthus, which were by him planted with monasteries, was raised to the see of Constantinople, in the year 845. There was, at that time, one Bardas, brother to the empress Theodota, niece to Michael, who had a great share in the government; he was desperately in love with his daughter-in-law, and had familiarity with her. Ignatius reproved his crime with such freedom as became a holy bishop, and, perceiving that Bardas did not repent, refused to admit him to the sacraments. This refusal incensed Bardas; but he waited till another time to shew his resentment. He persuaded Michael to take the government into his own hands, and to confine his mother and sisters in a nunnery. The emperor ordered the patriarch to do it; but he refused, which furnished Bardas with an opportunity to charge him with favouring the rebellion of a man, who called himself the son of Theodota by another husband. Michael caused his mother and sisters to be shut up, and banished Ignatius to the island of Terebinthus, requiring him to resign; and though the patriarch refused so to do, yet the emperor put Photius into his place.

Ignatius, within two months after Photius's advancement to the see of Constantinople, was removed from the island of Terebinthus to that of Mitylene. Photius, having convened a synod, declared his deposition, and anathematized his person. Being desirous to have this judgment authorized by the bishop of Rome, he deputed two bishops to pope Nicolas I. who succeeded Benedict III. in the year 858, desiring him to send his legates to Constantinople, to restore ecclesiastical discipline, and wholly suppress the remains of the sect of the Iconoclasts, or opposers of images. The pope sent two bishops to Constantinople, in quality of his legates, named Zacharias and Radoaldus, with full power to regulate the affair of the Iconoclasts, and to take informations as to what concerned Ignatius, in order to make their report to the holy see. He at the same time wrote to the emperor against the deposition of Ignatius, and the ordination of Photius.

The two legates being come to Constantinople, in the year 861, were present at a council of 318 bishops, to which Ignatius was summoned. He appeared the first session, was pressed to resign, and upon his refusal, summoned to appear a second time before the synod. He was brought thither by force, and the council pronounced sentence of deposition against him.

This assembly took also into consideration the worship of images, which was there confirmed, and seven teen canons were passed relating to bishops, monks, and other clergymen. After this, Ignatius was closely confined, and by force compelled to sign an instrument, importing, that he owned himself unworthy of the episcopal dignity; that he had been preferred to it, by indirect means, and had not been a lawful professor of it. This confession under his hand having been extorted

from him, they would have obliged him to read it in publick; but he made his escape in the habit of a peasant, lay concealed in the islands, and sent a petition of appeal to the pope. The emperor, on the other hand, sent to Rome the acts of the council against him, and wrote to the pope, persuading him to consent to the deposing of Ignatius, and the ordination of Photius: but Nicolas I. answered, that he disapproved of both, and, calling a council at Rome, declared Photius deprived of the priesthood; ordered the restoring of Ignatius; and declared all the ordinations made by Photius void.

The patriarch Ignatius had been allowed to live in the island of Terebinthus; but Photius, making use of forged letters to accuse him of holding intelligence in the West, and writing against the emperor, caused him to be imprisoned. The fraud being discovered, Ignatius was set at liberty. Bardas was some time after put to death by the emperor's order; but this did not obstruct Photius's persuading the emperor Michael to assemble a council at Constantinople, in which he caused pope Nicolas to be accused, deposed, and excommunicated. This council was held in 866; but, the next year, Basilus, who had been declared emperor after the death of Bardas, having killed Michael, restored Ignatius, and banished Photius into a monastery. Ignatius immediately excommunicated Photius, and desired of the emperor, that a general council might be summoned.

This council met at Constantinople in the year 869. Donatus and Stephen, legates to pope Adrian II. who succeeded pope Nicolas in the year 867, presided in it. Only the bishops, who had adhered to the patriarch Ignatius, were admitted to the first session. The others, having afterwards renounced all communion with Photius, and acknowledged Ignatius, were admitted to the following sessions; so that the council consisted of 100 bishops. The judgment, given by the pope in the council at Rome, was approved. Photius was brought in and degraded, as were those he had ordained; his person was anathematized, and the acts of his council against pope Nicolas condemned. The worship of images was confirmed, and several regulations made for establishing peace and discipline in the eastern church, and for ordering the elections of patriarchs and bishops. These regulations are contained in twenty-seven canons. In conclusion, a very ample confession of faith was read, and signed by all the bishops, together with the acts of the council.

The First General Synod or Lateran Council, A. D. 1123.

This council, which approved the treaty made between the emperor Henry V. and pope Calixtus II. concerning the ceremony of bestowing the investiture of ecclesiastical possessions, which had occasioned warm disputes between the imperial court and that of Rome, was assembled by pope Calixtus in the palace of the Lateran at Rome, and consisted of above 300 prelates: which great number of bishops occasioned the name of General to be given to it, as it was to other numerous councils, held afterwards in the West, though the eastern bishops did not assist at them.

The Second General Lateran Synod or Council, A. D. 1139.

This council was assembled by pope Innocent II. in the palace of the Lateran, and was composed of near 1000 bishops, and thirty canons were made in it.

The Third General Lateran Synod or Council, A. D. 1179.

This council was convened by pope Alexander III. to reform a great number of abuses that had crept into the church, to regulate discipline, and to condemn the Albigenses, and other reputed heretics. This council was composed of about 300 bishops, and made twenty-seven canons.

The Fourth General Lateran Synod or Council, A. D. 1213.

This council was called by Innocent III. for the recovering of the Holy Land, and the reformation of the universal church. The prelates came to Rome, and composed a council of 412 bishops, almost 800 abbots and priors, and a great number of deputies of absent bishops. The Latin patriarchs of Constantinople and Jerusalem

Jerusalem assisted at it in person; those of Antioch and Alexandria sent deputies thither. The ambassadors of the emperor of Constantinople, of the king of Sicily, and of the kings of France, England, and Jerusalem, of Cyprus, Arragon, and other princes, were present. The pope opened the synod with a speech concerning the recovery of the Holy Land, and the reformation of the church. Then he caused to be read in full council some chapters, or regulations, about the discipline of the church, which were all drawn up in form. These chapters amount to the number of seventy.

These canons perfected the body of the canon law, and regulated the practice of ecclesiastical procedures, which are followed to this day. And this council is in so much esteem among the Canonists, that it is commonly cited, in the canon law, by the name of The General Council.

In this council, it is said, the patriarch of the Maronites united his nation with the church of Rome; that the question about the primacy of the archbishop of Toledo was debated; and that the pope instituted the order of the Crusaders; and approved the orders of St. Dominic and St. Francis.

This council, which was very numerous at the beginning, was dispersed in less than one month. The prelates, being tired with staying at Rome, did one after another ask leave to be gone, and the pope, if we may believe Matthew Paris, made them buy their permission to depart. The war of the Pisantines and Genoese, and the troubles of Italy, soon obliged the pope to put an end to the council.

The First General Synod, or Council of Lyons, A. D. 1245.

This council was assembled by pope Innocent IV. with a design to depose the emperor Frederic; and accordingly the pope pronounced a sentence of excommunication and deposition against him. Besides this, there were three other affairs handled in this council; viz. first, the assisting the empire of Constantinople against the Greeks; secondly, that of Germany against the Tartars; and thirdly, that of the Holy Land against the Saracens. The pope ordered a supply out of the revenues of benefices for the assistance of the empire of Constantinople. To stop the incursions of the Tartars into Poland, Russia, and Hungary, he advised the people to make ditches and build castles. As to the succours for the Holy Land, he exhorts the crusaders to repentance; grants them exemptions, privileges, and indulgences; destines the twentieth part of the revenues of benefices for their assistance; counsels the faithful to leave them, by their wills, sums, to be employed for that pious work; and forbids Christians to furnish the Saracens with arms or provisions.

The pope likewise published, in this council, divers regulations concerning the canon law; as about commissions, erections, the power of judges delegate, procedures touching appeals, accusations, excommunications, debts contracted by churches, and several other points of law.

The Second General Synod, or Council of Lyons, A. D. 1274.

The second general council of Lyons was called by Gregory X. in 1274, for three reasons given in the bull of indiction. I. For the re-union of the Greek church. II. For succours to the Holy Land. III. For the reformation of ecclesiastical discipline and of the lives of the clergy. The pope presided there in person. The Latin patriarchs of Constantinople and Antioch were there also, with about 500 bishops, seventy abbots, and 1000 other inferior prelates. The ambassadors of the kings of France, Germany, and Sicily, and those of Michael Paleologus, emperor of the East, were sent thither by their masters. James king of Arragon assisted at their first meeting; but the pope refusing to crown him, unless he would pay the tribute which his father had engaged himself to give to the holy see every year, he went away in wrath against the pope.

The first sitting of the council was held in the great church of Lyons on the 7th of May 1274. After the usual prayers, the pope made a speech, and proposed to the assembly the reasons, for which the council was assembled. He delayed the second session to the 18th of

the same month. In this session he made another harangue, and put off the council to the 28th of the same month, after having sent home part of the inferior prelates. Between these two sessions, the pope prevailed with the bishops and abbots to grant the tenth of their revenues for the space of six years, for the succour of the Holy Land.

The General Synod, or Council of Vienna, A. D. 1311.

This council, at Vienna in 1311, was called by Clement V. in order to judge what concerned the Templars. The first session was held the 16th of October: near three hundred bishops assisted at it. The second was held the 22d of May, 1312.

In this council the extinction of the order of the Templars was resolved upon, and the bull for it was published. The memory of Boniface VIII was defended, notwithstanding the instances of the king of France. A crusade was likewise resolved upon. They condemned the Beguards and Beguins, whose errors had been proscribed, and, during this council, the pope made divers constitutions, which are in the five books of Clementines, published by John XXII. and inserted in the body of the canon law; but some of those constitutions had been made before this council, and others after; and of those, which were made in the time of this council, none but such as regard faith, the regulations touching the privileges of Mendicants, the study of the languages in the universities, and the condemnation of the Beguards and Beguins, take any notice that they were approved.

The General Synod, or Council of Constance, A. D. 1414.

About the beginning of the XVth century, the church was divided, there being three popes instead of one, viz. John XXIII. Gregory XII. and Benedict XIII. To extinguish this schism, they had recourse to a general council, which should be acknowledged on all sides. John XXIII. called one at Rome, in consequence of the prorogation of that of Pisa by his predecessor: but, that city being in the possession of Ladislaus, he agreed with the emperor Sigismund, that the council should meet at Constance, and appointed it on the 7th of November 1414. Ladislaus, who was preparing to come and besiege John XXIII. in Bologna, was seized with a fit of sickness, which obliged him to return to Naples, where he died, leaving his kingdom to his sister Joan the second of that name, widow to William of Austria. John XXIII. being delivered from so formidable an enemy, departed for Constance, and arrived there the 20th of October. He opened the council the 16th of November: but nothing was done till next year.

In fine, after several summons, Benedict was declared contumacious, schismatical, and deposed by the council, in the twenty-seventh session, on the twenty-seventh of November.

After these three, who pretended to the popedom, had been deposed, it was necessary to chuse another pope, who should be universally acknowledged. Before they proceeded to the election, the council drew up articles for the reformation of the church, in its members, and in its head. They ordained a general council to be held, five years after this was ended; and that for the future one should be held every tenth year. That the pope might hasten the holding of that council, but not retard it: That whenever there should happen to be two pretenders to the pontificate, a council should be immediately held; and that the pretenders should be suspended from all power and jurisdiction, till such time as the council was begun: That, in case an election should be made through fear or force, it should be null; but that the cardinals should not proceed to a new election, till such time as the general council had determined the invalidity of that, which had been made. Then the council published, in the fortieth session, the articles of reformation, which the future pope should endeavour, with the council. These articles are eighteen in number. None of them were disputed, but that of the annates; however, it passed that they should be abolished.

After this the council ordered, that they should proceed to the election of a pope. And, that this election might

might be the more solemn, it was ordered, for this time only, that six prelates of every nation should be joined with the cardinals, and that he who should be chosen by two thirds of the cardinals, and two deputies of each nation, should be acknowledged for sovereign pontiff. This was immediately executed. The cardinals and deputies of the council went into the conclave, and unanimously elected Odon Colonna, cardinal-deacon of St. George, who took the name of Martin V. because he was elected on St. Martin's Day, 1417. He was enthroned that very day, and crowned the one and twentieth of the same month. He presided in the forty-second session, which was held on the 28th of December. In the forty-third session, which was held the 21st of March, 1418, he published some constitutions for the reformation of the church. But he did not make all the regulations projected by the council. In fine, to satisfy the decree of the council, he appointed the future council at Pavia, and put an end to the council the 22d of April.

The General Council of Basil, A. D. 1431.

This council was convened by pope Eugenius IV. in order to re-unite the Greek and Latin churches, but it could not succeed.

The General Council of Trent, A. D. 1545.

This was the last general council that has been held, the popes since that time not thinking fit to expose their authority to the encroachments that have been, and might again be made upon it by such assemblies.

This council was convened by pope Paul III. and assembled at Trent, a town on the confines of Tirol, between Italy and Germany, on the 13th of December. The bishops, at first, ordered the manner of proceeding in the council, and decreed, that they should not vote by nations, according to the precedents of the councils of Constance and Basil; that method appearing to them unfair, and being the occasion of disorder. It was therefore resolved, that every one should have the freedom to vote in his own person, and that the matters in question should be governed by the majority, according to the practice of the last Lateran council under Leo X. The protestants insisted upon a council perfectly independent of the pope. They pretended likewise, that the laity ought to have the liberty of voting: but to prevent such an imputation upon the council, they stiled themselves, The Holy Oecumenical Council, and not the council representing the universal church, (which latter was the form of the councils of Constance and Basil,) that the protestants might have no pretence of saying, that since the laity were members of the church represented, they ought also to be members of the church representing. The third session was held Feb. 4, 1546, where there were present five new cardinals, six archbishops, thirty bishops, and a great many abbots: here the creed of Constantinople was read; and, that there might be time given for the bishops upon their journey, the fourth session was prorogued to the 4th of April; at which there were present nine archbishops and forty-one bishops. Then, according to the custom of antient councils, the number of the canonical books of the Old and New Testament, and the traditions conveyed down by the church, from the apostles to the present age, were settled. The council likewise declared, that the vulgar Latin translation ought to be esteemed authentic. In the fifth session they decreed what was necessary to be believed concerning original sin; the council declaring amongst other things, "That though this sin be remitted in baptism, yet concupiscence, which is the effect of sin, remains." The sixth session, upon the occasion of some disturbances in Germany, was adjourned to the 13th of January, 1547, in which the decree concerning justification passed, wherein 33 errors were condemned; some of which were the tenets of the Pelagians, who allow too much to the will, assisted only by natural strength: Others of these censured opinions were held by the Lutherans, who ascribe all to the grace of God, which, say they, governs and over-bears the will by an irresistible force. The seventh session was held on the 3d of March, when they published a decree concerning the sacraments in general, i. e. concerning the number, person instituting, the necessity, efficacy, matter, form, and minister of the sacraments.

In the eighth session, held on the 11th day of March,

a translation of the council to Bononia was resolved on, upon the account of a report of the plague being in Trent; but this resolution being opposed by the bishops of Germany, who continued to sit at Trent, after the Italians were gone off, the council was re-commenced, or rather continued at Trent the first of May, under pope Julius III. in 1551. In the thirteenth session held that same year, October 11, a decree concerning the eucharist was read; in which the council concluded against the Sacramentarians, "That Jesus Christ was really present in the holy sacrament of the altar;" and against the Lutherans, they confirmed the doctrines of transubstantiation, the adoration of the host, and the presence of Jesus Christ, at other times besides that of actual receiving. They refused to define the point of communion under both kinds for the laity, and the sacrifice of the mass; that the protestant divines, who seemed very much concerned in the settling of these disputes, and to whom they had granted a safe-conduct, might have time to arrive, and propose the reasons of their opinions to the council. In the fourteenth session, begun Nov. 25, 1551, the doctrine of the church concerning the sacraments of penance and extreme unction were declared. As to penance, the council set forth the necessity and institution of this sacrament, how it differed from Baptism; and enlarged upon the three branches of it, viz. contrition, confession, and satisfaction: they likewise set forth the institution and effects of extreme unction. In the fifteenth session, begun the 15th of January, 1552, they granted a new safe-conduct to the protestants, and adjourned till the first of May, to give others time to represent their reasons to the council, concerning communion in both kinds, the sacrifice of the mass, and the sacraments of orders and marriage. The divines, in the meantime, held congregations to state the disputes about marriage, and to form decrees upon their conclusions, in order to propose them in the sixteenth session; which being appointed, and ready to commence on the 28th of April, they understood, that Maurice, elector of Saxony, having joined his troops with those of the marquis of Brandenburg and landgrave of Hesse, in defence of Lutheranism, had made himself master of Augsbourg, and seemed to threaten the security of Trent.

This turn of affairs obliged the legates to suspend the council by the permission of Julius III.; neither had they any opportunity of setting it on foot again during the pontificates of Marcellus II. and Paul IV. But Pius IV. convened it again by his bull dated the 29th of November, 1560, to be held on Easter day the year following. In this bull, he did not make use of the term continuation; that word being very offensive to the protestants, because they knew themselves condemned in several articles in the former session of the synod. However, tho' the pope forbore the term, he expressed the thing, declaring, that the oecumenical council being suspended by reason of the wars, he took off this suspension, and convened it in the same town of Trent, with the consent of the emperor, kings, and other Christian princes. And because, at the time assigned for the new opening of the council, there was but nine bishops arrived at Trent; the first session, i. e. the seventeenth of the council, was not held till the 18th of January, 1562; in which a decree only was drawn up and read, declaring, that the council intended to treat upon all those heads, which they thought proper to compose the differences relating to religion, and which were necessary for the correction of abuses, the reformation of manners, and for the restoring of peace and good order to the church. In the eighteenth session, there was a decree made concerning the index or catalogue of prohibited books; but this index was not published during the sitting of the council, that the protestants might not be disoblige, by finding themselves condemned in their writings: there was likewise a safe-conduct granted not only for the Lutherans of Germany, but for all other nations.

In the twentieth session, the ambassadors of the king of France being arrived, embarrassed the council's proceedings: for these ambassadors not only demanded (like the imperialists) that the proposal of the Spaniards should be rejected, who would have had a declaration pass, that the council was only a continuation of the former; but the

French insisted on the contrary, that the council should be declared a new one; because otherwise not only the protestants of Germany, but likewise those of France, would never own it. To this the pope's legates having replied, that they had no commission to change any thing, and much less to make a new form of indiction, the ambassadors of the emperor and France acquiesced at last, for fear the council should break up. In the mean time, the ambassadors of the emperor and duke of Bavaria, those of Hungary and Bohemia, together with those sent from the French king, desired, that, for the gaining of the protestants, communion under both kinds might be allowed. This matter was discussed in several congregations; after which, in the twenty-first session, the council made a decree, that it was matter of faith to believe, that communicating in one kind, as to the laity, and clergy that do not consecrate, is sufficient for salvation; and so, without dwelling upon this point any longer, they examined the sacrifice of the mass; the decree concerning which, being read in the twenty-second session, sets forth, "That the unbloody sacrifice of the eucharist is a daily representation of that upon the cross; that it is propitiatory for the living, and for the faithful who are deceased; that it is offered to God alone, tho' sometimes in honour of the saints, and out of regard to their memory." Afterwards having, according to their customary proceedings, made two decrees for the reformation of manners and discipline, they fixed the twenty-third session for the 12th of November; but the emperor Ferdinand, and king Charles IX. of France, insisting upon a reformation of the court of Rome, they were obliged to defer it till July 1563.

Now the pope having satisfied these princes, by letting them understand, that he had already begun the reformation desired, and that his zeal in this matter would go on as far as could be reasonably expected, the twenty-third session commenced on the 15th of July, in which the council decreed the doctrine of the sacrament of orders, i. e. "That there were always seven orders in the church, some of which are greater than others: that those only are priests, who receive ordination from bishops: that orders are a sacrament, &c." In the twenty-fourth session held the 11th of November, the council declared, "That marriage is a true sacrament; that the state of marriage ought not to be preferred to virginity or celibacy, &c." The twenty-fifth and last session was held upon the 3d and 4th of December, in which there were three decrees published concerning purgatory, invocation of saints, and the use of indulgences. After this, the council remitted all disputes and contested senses, which might arise concerning the meaning of their decrees, to the pope's determination. And thus ended this famous council, which had been thrice convened in the space of eighteen years, having continued from 1545 to 1563, under the pontificates of five popes, viz. of Paul III. Julius III. Marcellus II. Paul IV. and Pius IV.

In England, every bishop was obliged (formerly) to hold a synod in his diocese once a year. This Lindwood seems to deliver as the rule of the English church: and the same is established in the designed reformation of the canons, drawn up in the reign of king Henry VIII.

To these annual synods all the clergy, who had any benefice within the diocese, were obliged to come, under the penalty of suspension. The regulars too, as well abbots as monks, were bound to this attendance; excepting those, who, in process of time, were exempted from episcopal jurisdiction. If the diocese was small, and had but one archdeaconry in it, the whole clergy met together at once. If it were larger, the bishop sometimes divided his synods according to the number of his archdeacons, and held his diocesan council at several times, and in several places: but still the method of business was the same in all.

The form of holding these diocesan synods was as follows. The clergy, in solemn procession, came to the church assigned, at the time appointed by the bishop, and seated themselves according to the priority of their ordinations. Then the deacons and laity were admitted. The bishop, or, in his absence, the vicar, when the

office for the occasion was over, made a solemn exhortation to the audience. Then a sermon was preached; after which, if the clergy had any complaints to make, or any thing else to offer, they were heard by the synod. The complaints of the clergy being over, the laity made theirs. Then the bishop proposed his diocesan constitutions to them. After which, if nothing remained to be done, he made a synodical exhortation, by way of injunction to the clergy; and all concluded with solemn prayers suited to the business. The form, at the conclusion of the first day, called *Benedictio primæ diei*, was this: *Qui dispersos Israel congregat, ipse vos hic & ubique custodiat. Amen. Et non solum vos custodiat, sed ovium suarum custodes idoneos efficiat. Amen. Ut cum summo pastore Christo de gregum suarum passione gaudeatis in coelo. Amen. Quod ipse parare dignetur, &c.* The benedictions of the other days were much to the same purpose.

The common time allowed, for dispatching the business of these synods, was three days; and a rubric was settled, to direct the proceedings in each of them. But, if the business could be dispatched in a shorter time, the assembly continued no longer than was necessary.

The first thing done, in these diocesan synods, was the bishop's making his synodical enquiries, of which the ancient forms are still extant. Next the synodical causes were heard. Then the bishop reported to his clergy what had been decreed in larger provincial synods. And, lastly, he published his own diocesan constitutions, which being read, and agreed to by the synod, were from that time in force within the diocese, provided they were not contrary to the decrees of some superior council of the province. Of these we have several collections published in the volumes of the English councils, and many more are still remaining in the bishops registers.

These diocesan synods were continued in England till the reign of Henry VIII. that is, till the commencement of the reformation.

SYNODICAL, something belonging to a synod; thus synodical epistles are circular letters written by the synods to the absent prelates and churches, or even those general ones directed to all the faithful, to inform them of what had passed in the synod. For the synodical month, see the article MONTH.

SYNONYMOUS is applied to a word or term that has the same import or signification with another.

Some severe critics condemn all use of synonymous terms in the same period; but this is to condemn all antiquity: so far is the use thereof from being vicious, that it is frequently necessary; as synonyma's contribute both to the force and clearness of the expression.

SYNONYMY, *Synonymia*, in rhetoric, a figure whereby synonymous terms, that is, various words of the same signification, are used, to amplify the discourse.

The word is formed from the Greek, *συν*, with, and *ωνυμα*, name.

SYNOVIA, or *SINOVIA*, in medicine, a term used by Paracelsus, and his school, for the nutritious juice proper and peculiar to each part; thus they talk of the synovia of the joints, of the brain, &c.

Others use synovia for the gout, and other diseases of the joints, arising from a vice in the nutritious juice through a wounded part, especially a joint.

Van Helmont defines synovia a kind of transparent mucilage like seed, such as issues from the legs of a calf upon cutting off the feet.

SYNTAGMA, *συνταγμα*, the disposing or placing of things in an orderly manner.

SYNTAX, *συνταξις*, in grammar, the construction or connection of the words of a language into sentences, or phrases.

F. Buffier more accurately defines syntax, the manner of constructing one word with another, with regard to the different terminations thereof, prescribed by the rules of grammar.

Some authors, as M. Vaugelas, &c. confound syntax with style; but there is a real difference.

The office of syntax is to consider the natural suitability of words with respect to one another, in order to make them agree in gender, number, person, mood, &c.

To offend in any of these points, is called to offend against syntax; and such kind of offence, when gross, is called a solecism; and when more slight, a barbarism.

The several parts of speech are, with regard to language, what materials are with regard to a building. How well prepared soever they may be, they will never make a house, unless they be placed conformably to the rules of architecture. It is properly the syntax that gives the form to language, and it is that on which turns the most essential part of grammar.

There are two kinds of syntax; the one of concord, wherein the words are to agree in gender, number, case, and person. The other of regimen or government, wherein one word governs another, and occasions some variations therein.

The first, generally speaking, is the same in all languages, as being the natural series of what is used almost every-where, the better to distinguish discourse. Thus, the distinction of two numbers, singular and plural, has rendered it necessary to make the adjective agree with the substantive in number: that is, to make the one singular or plural, when the other is so: for, as the substantive is the subject confusedly, though directly, marked by the adjective; if the substantive expresses several, there must be several subjects expressed in that form by the adjective; and, by consequence, it ought to be in the plural: as, *homines docti*, learned men: but, there being no variety of termination in the adjective, in English, to distinguish the number, it is only implied.

The distinction of masculine and feminine gender obliges the languages, which have distinct terminations, to have a concordance or agreement between the substantive and adjective, in gender as well as number: and for the same reason, the verbs are to agree with the nouns and pronouns, in number and person. If at any time we meet with any thing that seems to contradict these rules, it is by a figure of speech, that is, by having some word understood, or by considering the thoughts rather than the words themselves.

The syntax of government, on the contrary, is generally arbitrary; and, on that account, differs in most languages. One language, for instance, forms their regimen by cases; as the Latin and Greek: others use particles in lieu thereof; as the English, French, Italian, Spanish, &c.

One or two general rules, however, may be here noted, which obtain in all languages. 1. That there is no nominative case but has a relation to some verb, either expressed or understood; since we do not only speak to express what we perceive, but to express what we think of what we perceive, which is done by the verb.

2. That there is no verb but has its nominative case either expressed or understood; for the office of the verb being to affirm, there must be something to affirm of; which is the subject or nominative case of the verb; except before an infinitive, where it is an accusative; as, *Scio Petrum esse doctum*, I know Peter to be learned.

3. That there is no adjective but has a relation to some substantive; in regard the adjective marks confusedly the substantive, which is the subject of the form or quality distinctly marked by the adjective.

4. That there never comes any genitive case but what is governed by some other noun.

5. The government of verbs is frequently taken from various sorts of references, included in the cases, according to the caprice of custom or usage; which yet does not change the specific relation of each case, but only shews that custom has made choice of this or that. — Thus, the Latins say, *juvare aliquem & opitulari alicui*; the French, *servir quelqu'un et servir a quelque chose*; and, in Spanish, the generality of verbs govern indifferently a dative and an accusative case.

SYNTAXIS, in medicine, an attenuation or colliquation of the solids of the body; such as frequently happen in atrophies, inflammations of the bowels, colliquative fevers, &c. wherein a fatty, uliginous matter is voided with the excrements by stool.

SYNTHESIS, composition, or the putting of several

things together: as in making a compound medicine of several simple ingredients, &c.

The word is formed from the Greek, *συν*, with, and *θεσις*, positia.

SYNTHESIS, in logic, denotes a branch of method opposite to analysis, called the synthetic method. See METHOD.

SYNTHESIS, in surgery, is an operation whereby divided parts are re-united, as in wounds, fractures, luxations, &c.

SYNTHETIC, or SYNTHETICAL, is, according to Dr. Shaw, a term given to that part of chemistry, which, after the analytical chemistry has taken bodies to pieces, or reduced them to their principles, can, from these separated principles, either recompound the same body again, or, from the mixtures of the principles of one or more bodies in various manners, form a large set of new productions, which would have been unknown to the world but for this art: such productions are brandy, soap, glass, and the like. Synthetical chemistry, taken in the strict sense for the recombination of bodies from their own principles, is rather of philosophical than of ordinary use. This, however, is not easy, except in a few cases; nor are we to imagine, because it has been done in some, that nature has taken this way to compose them; her method of composition of bodies are a new subject, and worthy a diligent enquiry.

SYNUSIASTS, a sect of heretics, who maintained, that there was but one nature, and one single substance in Jesus Christ. The Synusists denied, that the Word assumed a body in the womb of the virgin, but held, that a part of the Divine Word being detached from the rest, was there changed into flesh and blood. Thus they taught, that Jesus Christ was consubstantial to the Father, not only as to his divinity, but even as to his humanity and very body.

SYRINGA, in botany, a plant, the flower of which has a small, tubulous, permanent empalement of one leaf, indented in four parts; it has one petal, with a long cylindrical tube, cut into four obtuse segments at the brim, which spread open, and two very short stamens, terminated by small summits, standing within the tube; it has an oblong germen, supporting a short slender style, crowned by a thick bifid stigma. The germen afterwards turns to an oblong, compressed, acute-pointed capsula, with two cells, opening with two valves contrary to the partition, including in each cell one oblong acute-pointed seed, with a membranaceous border.

There are three species of this plant, namely, 1. The syringa with oval heart-shaped leaves; or blue lilac; 2. Syringa with spear-shaped leaves, commonly called Persian jasmine. 3. The syringa with entire spear-shaped leaves, and others which are cut and jagged; commonly called cut leaved Persian jasmine.

The first sort of these plants is very common in the English gardens, where it has been long cultivated as a flowering-shrub. It is supposed to grow naturally in some parts of Persia, but is so hardy as to resist the greatest cold of this country. There are three varieties of this shrub, which are commonly cultivated in the English gardens, which differ in the colour of their flowers, and also in that of their shoots and leaves; one of these has white flowers, one blue, and the third has purple flowers; the latter is commonly known by the title of Scotch lilac, to distinguish it from the other. This is the most beautiful of the three, and is probably called the Scotch lilac, because it was first mentioned in the catalogue of the Edinburgh garden.

These shrubs grow to the height of eighteen or twenty feet in good ground, and divide into many branches; those of the white sort grow more erect than the other, and the purple or Scotch lilac has its branches more diffused than either. The branches of the white are covered with a smooth bark, of a grey colour; those of the other two are darker. The leaves of the white are of a very bright green, but those of the other are of a dark green; their shape and size are so near as not to be distinguished thereby. They are heart-shaped, and are placed opposite. The buds of the future shoots, which are very turgid before the leaves fall, are of a very bright green

green in the white sort, but those of the other two are of a dark green. The flowers are always produced at the ends of the shoots of the former year, and below the flowers come out shoots to succeed them; for that part upon which the flowers stand, decays down to the shoots below every winter. There are generally two bunches or panicles of flowers joined at the end of each shoot; those of the blue are the smallest, and are placed thinner than either of the other. The bunches on the white are larger; the flowers are closer placed, and larger than the blue; but those of the Scotch are larger, and the flowers are fairer than those of either of the other, so make a much finer appearance. The panicles of flowers grow erect, and being intermixed with the fine green leaves, have a fine effect; and if we add to this the fragrantcy of their flowers, it may be ranged among the most beautiful shrubs which now decorate the English gardens. They flower in May, and when the season is cool, these shrubs will continue three weeks in beauty, but in hot seasons the flowers soon fade. Their seeds are ripe in September, which, if sown soon after, the plants will come up the following spring; but as their roots send out great plenty of suckers annually, so few persons ever take the trouble to propagate these plants by seeds. I have raised several plants of the three sorts from seeds, and constantly found them prove the same as the shrubs from which the seeds were taken. These plants do generally flower the third year from seed; and I have always found these plants not so apt to send out suckers, as those which were produced by suckers, so are much more valuable; for the others put out such plenty of suckers, as that if they are not annually taken from the plants, they will starve them.

These plants thrive best upon a light rich soil, such as the gardens near London are for the most part composed of; and there they grow to a much larger size, where they are permitted to stand unremoved, than in any other part of England; for in strong loam, or upon chalky land, they make little progress. If the suckers are small when they are taken from the old plants, they should be planted in a nursery, in rows, three feet asunder, and one foot distance in the rows, where they may stand a year or two to get strength, and then they should be removed to the places where they are to remain. The best time to transplant these shrubs is in autumn.

The second sort grows naturally in Persia, but has been long cultivated in the English gardens, where it is best known among the gardeners by the name of Persian jasmine. This is a shrub of much lower growth than the former, seldom rising more than six or eight feet high. The stalks of this shrub are woody, covered with a smooth brown bark; the branches are slender, pliable, and extend wide on every side; these frequently bend downward where they are not supported; they are garnished with narrow spear-shaped leaves, placed opposite, of a deep green colour, ending in acute points. The flowers are produced in large panicles at the end of the former year's shoots, in like manner as the former; they are of a pale purple colour, and have a very agreeable odour. These appear the latter end of May, soon after those of the common sort, and continue longer in beauty; but these do not perfect their seeds in England.

The third sort differs from the second in having two sorts of leaves; those on the lower part of the branches are for the most part entire; these are broader and shorter than those of the second, and do not end in so sharp points. The leaves on the younger branches are cut into three or five segments, like winged leaves almost to the mid-rib. The branches of this sort are slender and weaker than those of the second; their bark is of a darker brown, and the flowers of a brighter purple colour.

This was brought into Europe before the other, and came by the Persian title Agem. Both these sorts are usually propagated by suckers, which their roots send out in great plenty; these should be carefully taken off from the old plants in the autumn, and planted in a nursery in the same manner as is before directed for the first, where they may grow two years to get strength,

and may then be transplanted to the places where they are designed to remain. The plants which are so propagated are always very prolific in suckers; for which reason it will be a better way to raise them by laying down their young branches, which in one year will be sufficiently rooted to transplant, and may be treated in the same way as the suckers. *Miller's Gard. Dict.*

SYRINGE, an instrument serving to imbibe, or suck up; a quantity of any fluid, and so squirt or expel the same with violence.

The word is formed from the Greek *σφινγξ*, or Latin *syrinx*, pipe.

SYRUP, or SYROP, in pharmacy, is a liquid form of medicine, prepared of decoctions, juices, or infusions, preserved by means of honey or sugar, and reduced to such a consistence, that a drop let fall on a marble does not spread.

Syrups, like other officinal preparations, may be made to answer various intentions, and consequently, may be either of a cooling, heating, drying, inciding, expectorating, incrustating, diuretic, sudorific, lithontriptic, alexiterial, or corroborating quality, according to the different virtues of the general rules for the making of syrups.

1. The sugar, employed for syrups made without coction, should first be boiled with water to a candy consistence; observing to clarify it with the whites of eggs, and by despumation. But the whitest and purest sugar, and sugar-candy, do not require this labour. The sugar thus prepared ought afterwards to be powdered, that it may dissolve the easier.

2. Though a double weight of sugar, in proportion to the liquor, may be required in making such syrups; yet a less proportion will generally suffice. First, therefore, dissolve only an equal quantity of sugar; then, by degrees, add a little more in powder, till it remain undissolved, at the bottom, to be afterwards incorporated by the gentle heat of a water bath.

3. Acid syrups, or those made with the juices of fruits, should not be put into copper vessels, unless such as are tinned.

4. What should be observed of decoctions in general, is also to be understood of decoctions for syrups. The vegetables, used either for decoctions or infusions, are to be moderately dried, unless they are expressly required fresh gathered.

5. Syrups made by coction are to be clarified with the white of eggs, except diacodium; which, therefore, requires the purest sugar.

The solutive and purging syrups ought rather to be made of brown sugar.

SYSSARCOSIS, in anatomy, a particular species of the kind of articulation, called also symphysis.

The syssarcosis is a natural union of two bones by means of flesh or muscles, such is that of the os hyoides and omoplate.

Syssarcosis is also used by some chirurgical writers to express a method of curing wounds of the head when the cranium is laid bare, and the interstice between the lips of the wound too wide for a contraction, by means of promoting the granulation or growth of new flesh.

SYSTEM, *Systema*, in general denotes an assemblage or chain of principles and conclusions, or the whole of any doctrine, the several parts whereof are connected together and follow or depend on each other; in which sense we say, a system of philosophy, a system of divinity, &c.

SYSTEM, in astronomy, denotes an hypothesis or supposition of a certain order, and arrangement of the several parts of the universe; whereby astronomers explain all the phenomena or appearances of the heavenly bodies, their motions, changes, &c.

The most celebrated hypotheses, or systems of the world, are three, viz. the Ptolemaic, Tychonic, and Pythagorean, or Copernican system.

Ptolemaic SYSTEM, so called from its inventor, Claudius Ptolemæus, a famous astronomer of Pelusium, in Egypt, supposes the earth immoveably fixed in the center, not of the world only, but of the universe; and that the sun, the moon, the planets, and stars, all moved

moved about it from east to west once in 24 hours, in the order following, viz. the moon, Mercury, Venus, the sun, Mars, Jupiter, Saturn, the fixed stars; and, above all, the firmament of their primum mobile, or the sphere which gave motion to all the rest. See a representation of this system, plate CXXV. fig. 1.

This system was first invented and adhered to, chiefly, because it seemed to correspond with the sensible appearances of the celestial motions. They took it for granted, that the motions which those bodies appeared to have, were such as they truly and really performed; and not dreaming of any motion in the earth, nor being apprised of the distinction of absolute, relative, or apparent motion, they could not make a proper judgment of such matters, but were under a necessity of being misled by their very senses, for want of proper assistance which after-ages produced.

It is easy to observe, they had no notion of any other system but our own, nor of any other world but the earth on which we live. They thought nothing less than that all things were made for the use of man; that all the stars were contained in one concave sphere, and, therefore, at an equal distance from the earth; and that the primum mobile was circumscribed by the coelum empyreum of a cubic form, which they supposed to be the heaven, or blissful abode of departed souls.

It would scarce have been worth while to have said so much about so absurd an hypothesis (as this is now well known to be) were it not that there are still numerous retainers thereto, who endeavour very zealously to defend the same, and that for two reasons principally, viz. because the earth is apparently fixed in the center of the world, and the sun and stars move about it daily; and, also, because the scripture asserts the stability of the earth, the motion of the sun, &c.

These two arguments merit no particular answer. It is sufficient, with respect to the first, to say, that we are assured things may (nay must) appear to be, in many cases, what they really are not, nay, to have such affections and properties as are absolutely contrary to what they really possess. Thus a person sitting in the cabin of a ship under sail, will, by looking out at the window, see an apparent motion of the houses, the trees, &c. on the strand, the contrary way, but will perceive no motion at all in the ship. Also, a person sitting in a wind-mill, if the mill be turned about, he will see an apparent motion of the upright post the contrary way, but will not perceive any in the mill itself.

All those cases are exactly parallel to that of the earth; and it is as rational to assert the ship and the mill are really quiescent, and the other bodies positively in motion, as it is to insist on the motion of the sun, and the earth's being at rest in the center.

As to the scripture, as it was never intended for an institution of astronomy or philosophy, so nothing is to be understood as strictly or positively asserted in relation thereto, but as spoken only agreeably to the common phrase, or vulgar notion, of things. And thus Sir Isaac Newton himself would always say, the sun rises, and the sun sets; and would have said with Joshua, "Sun, stand thou still," though he well knew it was quite contrary in the nature of the thing.

Tychonic SYSTEM.—This is represented plate CXXV. fig. 2. It owes its origin to Tycho Brahe, a nobleman of Denmark, who lived in the latter part of the last century; he made his observations at Uraniburg (i. e. celestial tower) in the island of Weer or Huena. This philosopher, though he approved of the Copernican system, yet could he not reconcile himself to the motion of the

earth; and being, on the other hand, convinced the Ptolomean scheme, in part, could not be true, he contrived one different from either, which is represented by the diagram referred to.

In this the earth has no motion allowed it, but the annual and diurnal phenomena are solved by the motion of the sun about the earth, as in the Ptolomaic scheme; and those of Mercury and Venus are solved by this contrivance, though not in the same manner, so simply and naturally, as in the Copernican system; as is easy to observe in the figure.

After this scheme, had been proposed some time, it received a correction, by allowing the earth a motion about its axis, to account for the diurnal phenomena of the heavens; and so this came to be called the semi-Tychonic system. But this was still wide of the truth, and encumbered with such hypotheses, as the true mathematician and genuine philosopher could never relish.

Copernican SYSTEM. See the article **COPERNICAN SYSTEM.**

SYSTEM, in poetry, implies a certain hypothesis, or scheme, of religion, from which the poet is never to recede.

SYSTEM, in music, signifies a compound interval; or an interval composed, or conceived to be composed, of several lesser intervals.—Such as the octave, &c.

The concinnous systems are those consisting of such parts as are fit for music, and those placed in such an order between the extremes, as that the succession of sounds from one extreme to another, may have a good effect.

Inconcinnous systems are those where the simple intervals are inconcinnous, or ill-disposed, betwixt the extremes.

SYSTOLE, in anatomy, the contraction of the heart, whereby the blood is drawn out of its ventricles into the arteries; the opposite state to which is called the diastole, or dilatation of the heart.

The systole of the heart is well accounted for by Dr. Lower, who shews that the heart is a true muscle, the fibres of which are acted on like those of other muscles, by certain branches of the eighth pair of nerves inserted into it, which bring the animal spirits from the brain hither. By a flux of these spirits the muscular fibres of the heart are inflated and thus shortened, the length of the heart diminished, its breadth or thickness increased, the capacity of the ventricles closed, the tendinous mouths of the arteries dilated, those of the veins shut up by means of their valves, and the contained juice forcibly expressed in the orifices of the arteries.

Dr. Drake adds to Dr. Lower's account, that the intercostal muscles and diaphragm contribute to the systole, by opening the blood a passage from the right ventricle of the heart to the left, through the lungs, to which it could not otherwise pass, because the opposition the blood contained in that ventricle must necessarily have made to its constriction, is taken off. Both these authors make the systole the natural state, or action of the heart, and the diastole the violent one. Boerhaave, on the contrary, makes the systole the violent, and the diastole the natural state.

SYSTYLE, in architecture, that manner of placing columns where the space between the two first consist of two diameters, or four modules.

SYZYGY, in astronomy, a term equally used for the conjunction and opposition of a planet with the sun.

The word is formed from the Greek, *συσυγία*, which properly signifies conjunction.

On the phenomena and circumstances of the syzygies, a great part of the lunar theory depends. See **MOON**.

T.

T A B

T a consonant, and the nineteenth letter in the alphabet. The letter T was in the same form in the old Greek alphabet, and was derived from the Phœnician or Samaritan character Tau τ , by placing the horizontal line or stroke quite upon the top of the perpendicular one. It is formed in the voice from a strong expulsion of the breath through the mouth, upon a sudden detraction of the tongue from the fore part of the palate, with the lips at the same time open.

T, has its proper sound in *tan, tin, ten, ton, tun, fat, let, hit, hot, put*. When it comes before (i) followed by another vowel, it is sounded like S, as in *nation, potion, expiate, &c.* When aspirated, that is, when *h* comes after it, it has a twofold sound; one clear and acute, as *thin, theory, &c.* the other more obscure and obtuse, as in *thine, those, their, &c.* It is said by some, that T sounds like *ch* before *eous, ous, uous*; as in *beauteous, portentous, tortuous*; but this seems a vicious pronunciation.

Among the ancients, T, as a numeral, stood for one hundred and sixty; and with a dash at the top, thus $\overline{T}$, it signified one hundred and sixty thousand.

When the tribunes approved of the decrees of the senate, they testified their consent by subscribing a T.

In music, T, stands for tutti, all, or altogether.

T, or TAU, in heraldry, is a kind of cross patent, or truncated; found in all the armories of the commanders of the order of St. Anthony.

TABBY, in commerce, a kind of rich silk which has undergone the operation of tabbying.

TABBYING, the passing a silk or stuff under a calender, the rolls of which are made of iron or copper, variously engraven, which bearing unequally on the stuff renders the surface thereof unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, TABLET, in pharmacy, is much the same with troches and lozenges, being a solid preparation formed into a little cake, or mass, of different figures, intended to dissolve slowly, and generally made agreeable to the palate. This form is mostly made use of for the more commodious exhibition of certain medicines, by fitting them to dissolve slowly in the mouth so as to pass by degrees into the stomach; and hence these preparations have generally a considerable proportion of sugar or other such materials. They are calculated for children who are not easily prevailed on to take medicines in less agreeable forms. There are various kinds of them, as the *tabellæ antacidæ, tabellæ anthelminticæ, tabellæ purgantes, &c.*

TABERNACLE, among the Hebrews, a kind of building, in the form of a tent, set up, by express command of God, for the performance of religious worship, sacrifices, &c. during the journeying of the Israelites in the wilderness; and, after their settlement in the land

T A B

of Canaan, made use of for the same purpose till the building of the temple of Jerusalem. It was divided into two parts, the one covered, and properly called the tabernacle; and the other open, called the court. The curtains which covered the tabernacle were made of linen, of several colours, embroidered. There were ten curtains, twenty-eight cubits long and four in breadth. Five curtains fastened together made up two coverings, which covered all the tabernacle. Over these there were two other coverings; the one of goat-hair, and the other of sheep-skins. The holy of holies was parted from the rest of the tabernacle by a curtain made fast to four pillars, standing ten cubits from the end. The length of the whole tabernacle was thirty-two cubits, that is, about fifty feet; and the breadth twelve cubits, or nineteen feet. The court was a spot of ground one hundred cubits long, and fifty in breadth, enclosed by twenty columns, each twenty cubits high and ten in breadth, covered with silver, and standing on copper bases, five cubits distant from one another; between which, there were curtains drawn, and fastened with hooks. At the east end was an entrance, twenty cubits wide, covered with a curtain hanging loose.

The tabernacle was finished, and set up on the first day of the first month of the second year, after the departure out of Egypt. When it was set up, a dark cloud covered it by day, and a fiery cloud by night. Moses went into the tabernacle to consult the Lord. It was placed in the midst of the camp, and the Israelites were ranged orderly about it, according to their several tribes. When the cloud arose from off the tabernacle, they decamped; the priests carried those things which were sacred, and the Levites all the several parts of the tabernacle. Part of the tribes went before, and the rest followed; and the baggage of the tabernacle marched in the center.

The learned Spencer has endeavoured to prove, that the Jewish tabernacle, and all its furniture, was an imitation of the portable temples of the heathens, and of the custom of carrying their gods along with them, in their migrations from one country to another.

Feast of TABERNACLES, a solemn festival of the Hebrews, observed after harvest, on the fifteenth day of the month Tisri, instituted to commemorate the goodness of God, who protected the Israelites in the wilderness, and made them dwell in booths, when they came out of Egypt. On the first day of the feast, they began to erect booths of the boughs of trees; and in these they were obliged to continue seven days. The booths were placed in the open air, and were not to be covered with cloths, nor made too close by the thickness of the boughs; but so loose that the sun and the stars might be seen, and the rain descend through them. In these they eat, and drank, and slept, during the continuance of the festival. But sick persons who could not bear the smell of the earth, might stay at home: the rabbins also freed women and

little

little children from this obligation. If the rain likewise proved so great that they could not live dry, or the cold so intense that it endangered their healths, they might all return to their houses.

In the time of Nehemiah, they made their booths, some upon the roofs of their houses, which were flat, some in their court-yards, and some in the streets.

The command, in the law, concerning the boughs and branches of trees to be used in this festival, being expressed in a general way, "Ye shall take unto you, upon the first day, boughs of goodly trees," there arose a dispute between the Pharisees and the Sadducees, for what end these boughs and branches were appointed. The Sadducees held that they were for making of the booths; but the Pharisees determined that these were branches and fruit of trees, that they were to carry in their hands at this festival.

Upon the first day of the feast, therefore, they prepared branches of palm, willow, and myrtle, and tied them together with gold or silver twist, or with other strings or twigs; and these they carried in their hands all the time of the feast. Once every day, they came into the court of the temple and walked round the altar, and held their boughs bending towards it; and cried Hosanna, or "Save now, O Lord; O Lord, send us now prosperity." Upon the seventh day, they compassed the altar seven times; this was called the great Hosanna; and every day, when they went away, they said, "Beauty be to thee, O altar! Beauty be to thee, O altar!"

The ceremony of drawing, and pouring out of water gave them the greatest joy and delight, of any that belonged to this festival; inasmuch that the Talmudists have this noted saying. "He who never saw the rejoicing of drawing water, never saw rejoicing in all his life." The manner was thus: When the parts of the daily sacrifice were laid upon the altar, one of the priests, with a golden vessel, went to the fountain of Siloam, and there filled it with water. He returned back into the court, through the water-gate; and when he came there, the trumpets sounded. Then he went up to the rise of the altar, where stood two basins, one having wine in it; and into the other he poured the water: next he poured either the wine into the water, or the water into the wine, and lastly poured them out mixed together by way of libation.

This custom is supposed to be alluded to by our Saviour, when he cried, upon the last and great day of the feast, "If any man thirst, let him come unto me and drink, &c." It is difficult to find a tolerable reason for this practice at the feast of tabernacles, especially since the Jewish writers afford no satisfaction concerning it. Probably it might be done in memory of that water, which followed the Israelites, all the time they were in the wilderness, without which they must have perished.

After the service of the daily sacrifice were offered the additional sacrifices, which, with the daily sacrifices of the time, amounted to two hundred and fifteen, the number of years that the Israelites continued in Egypt. At this festival all the four and twenty courses of the priests attended; and it was so managed, that every course should have a share in offering one beast or other every day till the solemnity ended.

At the offering of these additional sacrifices there were peculiar psalms sung by the Levites; and when these sacrifices were finished, the people went home to dinner, after they had sung their Hosanna about the altar, with their palms in their hands. After dinner, they usually spent some time in the divinity-schools, or in the study of the law, till the time of the evening sacrifice.

About night, they began their rejoicing for the pouring out of water. For this purpose, they went into the court of the women, who were placed in balconies round about the court.

Here the Levites, with their harps, psalteries, cymbals, and other instruments, began to play. In the mean time, the elders of the people, the members of the Sanhedrim, rulers of the synagogues, doctors of the schools, and all who were distinguished by the dignity of their office, fell a dancing, leaping, and capering, singing songs and doxologies, with lighted torches in their hands; and this wild sort of devotion held for the greatest

part of the night. At last, when the night was far advanced, two priests, standing in the gate of Nicanor, blew their trumpets; and this concluded the solemnity.

TABERNÆMONTANA, in botany, a genus of plants, the flower of which has a small empalement, cut into five acute parts; it has one funnel shaped petal, with a long cylindrical tube, which is bellied at both ends, and at the brim is cut into five oblique segments; it has five small stamina in the middle of the tube, terminated by summits which join together, and two germs, supporting an awl-shaped style, crowned by decayed stigmas. The germen afterward turns to two bellied capsules, which are horizontally reflected, opening with one valve, having one cell, filled with oblong oval seeds, and surrounded with pulp.

There are two species of this plant. 1. Tabernæmontana with spear-shaped leaves, which are placed opposite, and flowers growing in a corymbus on the sides of the branches. 2. Tabernæmontana with oblong, oval, acute pointed leaves, which are placed opposite, and flowers growing in a corymbus, terminating the branches.

The first sort grows naturally in Jamaica, and some of the other islands in the West-Indies. This rises with an upright woody stalk to the height of fifteen or sixteen feet, covered with a smooth grey bark, which abounds with a milky juice, and sends out several branches from the side, which grow erect, garnished with thick leaves, which have a milky juice, of a lucid green, and have many transverse veins from the midrib to the border, standing opposite on foot stalks an inch long. The flowers come out in roundish bunches from the wings of the stalk; they are small, of a bright yellow colour, and have an agreeable odour. The tube of the flower is half an inch long; the brim is cut into five acute points, which spread open like those of the common jasmine. These flowers, in their native soil, are succeeded by two swelling capsules, joined at their base, but spread from each other horizontally, and are filled with oblong seeds, lying over each other like the scales of fish, and are included in a soft pulp.

The second sort was discovered by the late Dr. William Houstoun, in the year 1730, growing naturally at La Vera Cruz. This rises with a woody stalk ten or twelve feet high, covered with a wrinkled grey bark, sending out many branches towards the top, which are garnished with oblong oval leaves, of a lucid green, and of a thick consistence; they are five inches long and two and a half broad, rounded at both ends, but terminate with an acute point. These are placed opposite, and have short foot-stalks. The flowers come out in pretty large roundish bunches at the end of the branches; they are white, and smaller than those of the first sort, having an agreeable scent. These are succeeded by shorter and rounder pods, which spread from each other horizontally like the former.

Both these plants are very impatient of cold, so will not live in this country unless they are placed in a warm stove. They may be propagated by seeds or cuttings; if by seeds, they may be procured from the countries where the plants grow naturally; these should be sown early in the spring on a hot-bed, and when the plants are come up, they must be carefully transplanted into small pots, filled with light rich earth, and plunged into a hot-bed of tanners bark, being careful to shade them in the heat of the day, until they have taken new root; after which time they must have free air admitted to them every day when the weather is warm; but if the nights should prove cold, the glasses of the hot-bed should be covered with mats every evening, soon after the sun goes off from the bed. These plants must be often refreshed with water, but it must not be given to them in large quantities, especially while they are young; for as they are full of a milky juice, they are very subject to rot with much moisture.

The plants may remain during the summer season in the hot-bed, provided the tan is stirred up to renew the heat when it wants, and a little new tan added; but at Michaelmas, when the nights begin to be cold, the plants

plants should be removed, and plunged into the bark-bed in the stove; where, during the winter season, they must be kept in a moderate degree of warmth, and in cold weather they should have but little water given them. As these plants are too tender to live in the open air in this country, they should constantly remain in the stove, where, in warm weather, they may have free air admitted to them, by opening the glasses; but in cold weather they must be kept warm. With this management the plants will thrive and produce their flowers; and as their leaves are always green, they will make a pleasant diversity amongst other tender exotic plants in the stove.

These plants may also be propagated by cuttings during the summer season, which should be cut off from the old plants, and laid to dry in the stove five or six days before they are planted, that the wounded parts may heal, otherwise they will rot. These cuttings should be planted in pots filled with fresh light earth and plunged into the hot-bed of tanners bark, and closely covered with a hand-glass, observing to shade them from the sun in the middle of the day in hot-weather, as also to refresh them now and then with a little water. When the cuttings have taken root, they may be transplanted into separate pots, and treated in the same manner as those which are raised from seeds.

TABES, in medicine, or **TABES DORSALIS**, arises from a disorder of the spinal marrow, and is principally incident to persons of a falacious disposition, or such as are newly married. The patients are free from a fever, eat and digest well. The person labouring under this disorder, when interrogated with respect to his state, affirms, that he perceives, as it were, ants falling from the superior part of his body, his head, for instance, into the spine of the back; and, when he discharges his urine or excrements, there is, at the same time, a copious evacuation of liquid semen, in consequence of which, he is incapable of propagating his species, answering the purposes of marriage, or being amused with venereal dreams. He is generally short-breathed and weak, especially after running, or walking up a steep place; he perceives a sense of weight in his head, and is afflicted with a ringing of his ears. The patient is, in process of time, seized with various species of violent fevers, and at last dies of that kind of fever called lypiria.

This efflux of the nutritious juice being once stopped by art, the dispirited and impoverished blood must be replenished, as soon as may be, with new chyle, by such food as is delicious, and affords a good juice, and is most grateful to the patient's stomach; must be given often in a day, though in a little quantity at a time. And that the appetite may be the more excited, let him be advised to be cheerful; for there is nothing destroys the appetite, and confirms a consumption, more than grief or sadness. Let him also enjoy the benefit of the open air, which is beneficial to the nerves, and, consequently, to the appetite and stomach. But he must religiously abstain from wine and spirituous liquors, which are subject to put the blood, which before was too hot, into a greater flame. No purges are to be used to procure any other considerable evacuation, which may create farther expences to nature, when she is already weak.

TABLATURE, in anatomy, a division or parting the skull into two tables.

TABLE, in architecture, a smooth, simple member or ornament of various forms, but most usually in that of a long square.

A projecting table is that which stands out from the naked of the wall, pedestal, or other matter it adorns.

Raked-table, is that which is hollow in the die of a pedestal, or elsewhere, and is usually encompassed with a moulding.

Razed-table, is an embossment in a frontispiece for the putting an inscription, or other ornament, in sculpture. This is what M. Perrault understands by abacus in Vitruvius.

Crowned-table, that which is covered with a cornice, and in which a basso relievo is cut, or a piece of black marble incrustated for an inscription.

Rusticated-table, that which is picked, and whose surface seems rough, as in grottos, &c.

TABLE, in perspective, denotes a plain surface, supposed to be transparent, and perpendicular to the horizon. It is always imagined to be placed at a certain distance between the eye and the objects, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective-plane.

TABLE, in anatomy. The cranium is said to be composed of two tables, or laminæ, i. e. it is double, as if it consisted of two bones laid over one another.

TABLE of Pythagoras, or Multiplication TABLE. See **MULTIPLICATION.**

Laws of the twelve TABLES, were the first set of laws of the Romans, thus called either by reason the Romans then wrote with a style on thin wooden tablets covered with wax, or rather, because they were engraven on tables, or plates, of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to take in the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermodorus was first appointed to translate them, and the decemviri afterwards compiled and reduced them into ten tables. After a world of care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 303. The following year they found something wanting therein, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorized; all these being engraven on two other tables made the laws of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLES of the Law, in Jewish antiquity, two tables on which were written the Decalogue, or Ten Commandments, given by God to Moses on Mount Sinai.

Many questions have been started about these tables, as concerning their matter, form, number, author, and contents. Some suppose them to have been made of wood, others of precious stone. These again are divided; some supposing them to have been of ruby, and others of carbuncle. Some oriental authors pretend they were ten in number, and others seven, but the Hebrews acknowledge no more than two. Moses observes, that these tables were written on both sides: many think they were transparent, so that they might be read through: others are of opinion that the same Ten Commandments were written on each of the two tables; and others, that the ten were divided, five being written on one table and five on the other. Moses expressly says that these tables were written by the hand of God. Some understand this literally, others ascribe it to the ministry of an angel, and others explain it by an order of God to Moses himself, to write them. The Mahometans say that God commanded the archangel Gabriel to make use of the pen, which is the invocation of the name of God, and of the ink which is taken out of the river of light, and therewith to write the tables of the law. When Moses brought these tables down from the mount, and saw the idolatry into which the children of Israel had fallen, he dropt them out of his hand, and by the fall they were broken to pieces; but this loss was repaired by the second table which God gave to Moses, and in which he commanded him to write down the words of the covenant which he had made with Israel. From hence some conclude that these latter tables were not written by the hand of God, though the first were. But Moses takes express notice that God himself wrote them; whence it follows either that they were both written by the finger of God, or that neither of them was so written.

New TABLES, Tabulae novae, an edict, occasionally published in the Roman commonwealth, for the abolishing all kinds of debts and annulling all obligations.

TABLE, among the jewellers. A table diamond, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles; in which sense a diamond,

diamond, cut table-wise, is used in opposition to a rose-diamond.

TABLE is also used for an index or repertory put at the beginning or end of a book, to direct the reader to any passage he may have occasion for: thus we say table of matters, table of authors quoted, &c. Tables of the Bible are called Concordances.

TABLE of Houses, among astrologers, certain tables ready drawn up for the assistance of practitioners in that art, for the erecting or drawing of figures or schemes.

TABLE, in mathematics, a system of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations: thus we say, tables of the stars; tables of sines, tangents, and secants; tables of logarithms, rhumbs, &c. sexagenary tables; loxodromic tables, &c.

Astronomical TABLES, are computations of the motions, places, and other phenomena of the planets, both primary and secondary.

The oldest astronomical tables are the Ptolemaic, found in Ptolemy's *Almagest*; but these no longer agree with the heavens.

In 1252, Alphonso XI. king of Castile, undertook the correcting them, chiefly by the assistance of Isaac Hazan, a Jew; and spent four hundred crowns therein. Thus arose the Alphonsine tables, to which that prince himself prefixed a preface. But the deficiency of these was soon perceived by Purbachius and Regiomontanus; upon which the latter, and after him Waltherus and Warnerus, applied themselves to celestial observation, for the further amending them; but death prevented any progress therein.

Copernicus, in his books of the celestial revolutions, instead of the Alphonsine tables, gives others of his own calculation, from the latter, and partly from his own observations.

From Copernicus's observations and theories, Erasmus Reinholdus afterwards compiled the Prutenic tables, which have been printed several times, and in several places.

Tycho Brahe, even in his youth, became sensible of the deficiency of the Prutenic tables; which was what determined him to apply himself with so much vigour to celestial observation. Yet all he did thereby, was to adjust the motions of the sun and moon; though Longomontanus, from the same, to the theories of the several planets published in his *Astronomia Danica*, added tables of their motions, now called the Danish Tables; and Kepler likewise, from the same, in 1627, published the Rudolphine Tables, which are now much esteemed. These were afterwards, in the year 1650, turned into another form, by Maria Cunitia, whose astronomical tables, comprehending the effect of Kepler's physical hypothesis, are exceedingly easy, and satisfy all the phenomena, without any trouble of calculation, or any mention of logarithms; so that the Rudolphine calculus is here greatly improved.

Mercator made a like attempt in his *Astronomical Institutions*, published in 1676; and the like did J. Bap. Morini, whose abridgement of the Rudolphine tables was prefixed to a Latin version of Street's *Astronomia Carolina*, published in 1705.

Lansbergius, indeed, endeavoured to discredit the Rudolphine tables, and framed perpetual tables, as he calls them, of the heavenly motions; but his attempt was never much regarded by the astronomers; and our countryman Horrox gave an abundant check to his arrogance, in his *Defence of the Keplerian Astronomy*.

Nor was the authority of the Rudolphine tables impaired by the Philolaic tables of Bullialdus's hypothesis; or the Britannic tables of Newton; or the French ones of the count de Pagan, or the Caroline tables of Street, all calculated on Dr. Ward's hypothesis, or the Novalmagestic tables of Ricciolus. Among these, however, the Philolaic and Caroline tables are esteemed the best; inasmuch that Mr. Whiston, by the advice of Mr. Flamsteed, a person of undoubted authority in such cases, thought fit to subjoin the Caroline tables to his *Astronomical Lectures*.

The Ludovician tables were published in 1702, by M. de la Hire, wholly from his own observations, and with-

out the assistance of any hypothesis; which, before the invention of the micrometer, telescope, and the pendulum-clock, was held impossible. But the latest, and much the best, are those of the celebrated Dr. Halley.

TABOR, *Tabourin*, a small drum.

TABORITES, or THABOUTS, a branch or sect of the ancient Hussites. They carried the point of reformation farther than Huss had done, rejected purgatory, auricular confession, the unction of baptism, transubstantiation, &c. They reduced the seven sacraments of the Romanists to four, viz. baptism, the eucharist, marriage, and ordination.

TACAMAHACA, in the materia medica, a resin obtained from a tree resembling the poplar, bearing at the extremities of the branches small roundish fruits, including a seed like a peach-kernel; a native of the temperate parts of the continent of America, and in a sheltered situation enduring the winters of our own country.

Two sorts of this resin are sometimes to be met with. The best, called, from its being collected in a kind of gourd-shells, tacamahaca in shells, is somewhat unctuous and soft, of a pale yellowish or greenish colour, a bitterish aromatic taste, and a fragrant delightful smell approaching to that of lavender and ambergris. This sort is very rare. That commonly found in the shops is in semitransparent grains, or glebes, of a whitish, yellowish, brownish, or greenish colour, and of a less grateful smell than the foregoing. The first is said to exude from the fruit of the tree, the other from incisions made in the trunk. The tree, as raised among us, affords in its young buds, or the rudiments of the leaves, a resinous juice of the same kind of fragrance.

Tacamahaca is used chiefly as an ingredient in warm nervine plasters; though the fragrance and taste of the finer sort points out its being applicable to other purposes, as an internal balsamic corroborant. Both kinds dissolve in rectified spirit into a gold-coloured liquor, only a small quantity of impurities being left: they impregnate water also considerably with their smell and taste, but give out very little of their substance to this menstruum.

TACHYGRAPHY, *ταχυγραφία*, the art of writing fast, or of short-hand; of which authors have invented several methods.

TACTICS, in the art of war, is the method of disposing forces to the best advantage in order of battle, and of performing the several military motions and evolutions.

TADPOLE, a young frog, before it has disengaged itself from the membranes that envelope it in its first stage of life.

This animal furnishes the curious in microscopic observations with a beautiful view of the circulation of the blood, especially when it is young.

The method of procuring them for this purpose in the greatest perfection is this: let a small quantity of frog's spawn be kept some days in water, and from this will be produced a vast number of young tadpoles; these, while very young, are perfectly transparent, and, when placed before the double microscope, the heart may be easily seen, and its pulsation regularly observed; and the blood protruded thence may be beautifully seen circulating thro' the whole body; but particularly in the tail, where, tho' so very minute, more than fifty vessels may be seen at one view. The young brood grow more and more opaque every hour, and in a day or two the circulation of the blood can only be seen in their tail, or in the fins near the head.

TÆNIA, the TAPE-WORM, in zoology, a genus of worms, the body of which is of an oblong form, and composed of evident joints or articulations, in the manner of the links of a chain, or beads of a necklace.

The tape-worm grows frequently to several ells in length, and its articulations are a third of an inch long each. There is also another small species, which never exceeds two inches in length, and is commonly not more than half an inch.

TÆNIA, in architecture, a member of the Doric capital, resembling a square fillet, or reglet: it serves instead of a cymatium.

TAFFETY, in commerce, a kind of fine, smooth, filken, stuff, having usually a remarkable lustre or gloss.

There are taffeties of all colours, some plain, others striped with gold, silver, silk, &c. others chequered, others flowered, others in the Chinese point, others the Hungarian; with various others, to which the mode or the caprice of the workmen give such whimsical names, that it would be as difficult as it is useless to rehearse them; besides that, they seldom hold beyond the year wherein they first rose. The old names of taffeties, and which still subsist, are taffeties of Lyons, Spain, England, Florence, Avignon, &c. The chief consumption of taffeties is in summer-dresses for women, in linings, scarves, window-curtains, &c.

There are three things which contribute chiefly to the perfection of taffeties, viz. the silk, the water, and the fire. The silk is not only to be of the finest kind, but it must be worked a long time, and very much, before it be used. The watering, besides that it is only to be given very lightly, seems only intended to give that fine lustre, by a peculiar property not found in all waters. Lastly, the fire, which is passed under it to dry the water, has its particular manner of application whereon the perfection of the stuff depends very much.

Octavio May, of Lyons, is held the first author of the manufacture of glossy taffeties; and tradition tells us the occasion of it. Octavio, it seems, going backwards in the world, and not able to retrieve himself by the manufacture of taffeties, such as were then made, was one day musing on his misfortunes, and, in musing, chanced to chew a few hairs of silk which he had in his mouth. His reverie being over, the silk he spit out seemed to shine, and on that account engaged his attention. He was soon led to reflect on the reason; and, after a good deal of thought, concluded, that the lustre of that silk must come, first, from his having pressed it between his teeth. Secondly, from his having wet it with his saliva, which had something glutinous in it; and thirdly, from its having been heated by the natural warmth of his mouth. All this he executed upon the next taffeties he made; and immediately acquired immense riches to himself, and to the city of Lyons the reputation it still maintains, of giving the gloss to taffeties, better than any other city in the world.

It will not, we conceive, be less useful than curious, to give here the description of the engine contrived by Octavio to give the gloss to taffety; to add the manner of applying it, and the composition of the water used therein.

The machine is much like a silk loom, except that, instead of iron points, here are used a kind of crooked needles, to prevent the taffety from slipping: at the two extremities, are two beams; on one of which is rolled the taffety, to take the gloss; and on the other, the same taffety as fast as it has received it. The first beam is kept firm by a weight of about 200 pounds; and the other turned by means of a little lever passing through mortises at each end. The more the taffety is stretched, the greater lustre it takes; care, however, is to be used it be not over-stretched.

Besides this instrument for keeping the stuff stretched, there is another to give it the fire: this is a kind of carriage, in form of a long square, and the breadth of the taffeties. It moves on trundles, and carries a charcoal fire under the taffety, at the distance of about half a foot.

The two machines prepared, and the taffety mounted, the lustre is given it by rubbing it gently with a ball, or handful of lifts of fine cloth, as it rolls from one beam to the other; the fire, at the same time, being carried underneath it to dry it. As soon as the piece has its lustre, it is put on new beams to be stretched, a day or two; and the oftener this last preparation is repeated, the more it increases the gloss.

For black taffeties, the gloss is given with double beer, and orange or lemon juice; but this last is the least proper, as being apt to whiten. The proportion of the two liquors is a gallon of orange juice to be boiled together to the consistence of a rich broth. For coloured taffeties they use gourd-water, distilled in an alembic.

TAGETES, *Franch* **MARYGOLD**, or *African* **MARYGOLD**, in botany, the name of a genus of plants, the

flower of which is of the radiated kind; its disk is composed of floscules divided into several segments, and its outer edge of semi-floscules; all standing on embryo seed; and contained in a one-leaved cup of a tabulated form. The embryo's finally become seeds of an angular form, furnished with a foliaceous head, and affixed to the thalamus of the flower. There are also some species in which the flower is wholly composed of semi-floscules.

We have a great many species of this plant annually raised in our gardens, for the beauty of their flowers. They are propagated by sowing the seeds in spring, on a moderately hot-bed; when the young plants come up, they must have air allowed them; and, when three inches high, they should be removed to another hot-bed, which should be arched over with hoops that it may be sheltered with mats. They are to be planted here at about eight inches distance, and, when they are grown stronger, as about the beginning of May, they are to be taken up with a ball of earth about their roots, and placed where they are to remain; or else at eighteen inches distance in a nursery, where, when they flower, the finest sorts may be marked and removed, with a large ball of earth to their roots, either into pots, or into the borders of the flower-garden. They are very beautiful; but their smell is very offensive. *Miller's Gard. Dict.*

TAJACU, the **Musk-Hog**, in zoology, a species of hog, with a cyst on the back, and no tail: it is a native of Mexico, and is smaller than the common hog. On the middle of the head there arises a kind of crest, composed of a large cluster of bristles; and on the middle of the back there is a kind of cyst or gland, with an opening at the upper part, in which is secreted a perfumed fluid matter, of a mixt smell between that of musk and civet; whence the English name.

TAIL, *Cauda*, the train of a beast, bird, or fish; which, in land animals, serves to drive away flies, &c. and in birds and fishes, to direct their course, and assist them in ascending or descending in the air or water.

TAIL of a Comet, denotes the luminous rays issuing from a comet towards that part of the heavens from whence it seems to move. See **COMET**.

We have an enquiry into the cause of the tails of comets by Mr. Euler in the *Mem. de l'Acad. de Berlin*. He thinks there is a great affinity between these tails, the zodiacal light, and the aurora borealis; and that the common cause of them all is the action of the sun's light on the atmospheres of the comets, of the sun, and of the earth. He supposes that the impulse of the rays of light on the atmosphere of comets may drive some of the finer particles of that atmosphere far beyond its limits; and that this force of impulse, combined with that of gravity towards the comet, would produce a tail, which would otherwise always be in opposition to the sun, if the comet did not move. But the motion of the comet in its orbit, and about an axis, must vary the position and figure of the tail, giving it a curvature, and deviation from a line drawn from the center of the sun to that of the comet; and that this deviation will be greater, as the orbit of the comet has the greater curvature, and the motion of the comet is more rapid. It may even happen, that the velocity of the comet, in its perihelion, may be so great, that the force of the sun's rays may produce a new tail before the old one can follow; in which case the comet might have two or more tails. The possibility of this is confirmed by the comet of 1744, which was observed to have several tails, while it was in its perihelion.

TAIL of the Trenches, in the art of war, is the post or place where the besiegers begin to break ground.

Dragon's TAIL, in astronomy, the descending node of a planet.

Horse's TAIL, in the customs of the eastern nations, is the ensign, or flag, under which they make war.

TAIL, or **FEE-TAIL**, in law, is a limited estate, or fee; opposed to fee-simple.

Fee tail is an inheritance whereof a person is seised, to him and the heirs of his body, begotten or to be begotten; so that the tenant in tail cannot alien, either before or after issue had, or forfeit such lands, longer than for his own life; because an estate in tail always remains

mains to the issue of the donee and his heirs; or in case he has no issue, then to the donor and his heirs.

Estates-tail of lands are either general or special. General tail is where lands or tenements are given to a man, or woman, and the heirs of either of their bodies begotten; which is called a general tail, because however many wives a person that holds by this title shall have one after another in lawful marriage, his issue by them severally are all capable of inheriting in their turns: and if the woman has issue by several husbands, they may all inherit after each other, as heirs of her body. A tail-special, on the other hand, is when lands, &c. are limited to a man and his wife, and the heirs of their two bodies begotten, so that the children by a second wife, or former wife, stand absolutely excluded.

Where lands are granted to a man and his heirs-male, or heirs female of his body begotten, such male or female issue shall only inherit pursuant to the limitation: and hence it is, that where a grant is to a man and the heirs-male of his body begotten, and he has issue a daughter, who has a son, this son cannot inherit the estate, because he cannot prove his descent by heirs-male.

Where lands, &c. are given to a husband and wife, and the heirs of their two bodies begotten in special tail, and one of them dies without issue had between them; in such case, the survivor shall hold the lands for life, as tenant in tail after possibility of issue extinct, as the lawyers call it.

Nevertheless, as great mischiefs were occasioned by inheritances being intailed; as defrauding of creditors, &c. disobedience of sons, when they knew they could not be disinherited, and the like, the judges found out a way to bar an intailed estate with remainders over, by a feigned recovery.

TALC, or TALK, in natural history, a large class of fossil bodies, composed of broad, flat, and smooth laminae or plates, laid evenly and regularly on one another; easily fissile, according to the site of these plates, but not all so in any other direction; flexible and elastic; bright, shining and transparent; not giving fire with steel, nor fermenting with acid menstrua, and sustaining the force of a violent fire without calcining.

Venice talc is a soft smooth concrete, unctuous or sopy to the touch, of a white or pale greenish colour, with a silver-like lustre, generally found in small pieces. It may be split into numerous fine plates or leaves, which, singly, prove somewhat flexible and elastic, and perfectly pellucid, though the entire mass is commonly opaque, or at most only semitransparent. The smallest pieces are to be preferred; the larger, however white and apparently pure on the outside, being apt to have specks or veins of heterogeneous matter in the internal part. This mineral has received the epithet Venetian, not from its being originally the product of Venice, but probably from that city having formerly been a principal mart for it. Though it may perhaps be met with in some parts of the Venetian dominions, it is more common in other countries; in Muscovy, England, Norway, Hungary, Bohemia, Spain, and the Eastern nations.

Talc is generally supposed to be entirely unsubduable by fire. But Mr. Boyle relates, that having kept some Venice talc for a length of time in a glass-house furnace, it lost of its volume, its compactness, and its lustre, and became more brittle, though it still retained the appearance which it had at first. I have myself also observed a like effect, the talc by strong calcination having lost its lustre and unctuousity, though the diminution in weight was only one dram upon six ounces: some white vapours arose in the calcination, resembling those of the acid of sea-salt, but no spirit could be collected on repeating the operation in a retort; the talc here lost nothing of its weight, but had contracted a blackish hue. Morhoff in his epistle to Langelott on the transmutation of metals, declares that he has seen talc, in the space of half an hour and by a small fire, calcined into a spongy mass, friable betwixt the fingers into a subtile powder. Charas has already questioned this experiment, and we may be certain it was not performed on any true talc: probably the lapis specularis, or selenites, were mistaken for talc; a suspicion which is countenanced by the au-

thor's own words; he says the mineral was deprived of its yellow colour, a colour which those stones frequently have, but Venice talc has not. Though talc, however, in great measure resists the action of culinary fire, I have found it incapable of resisting the concentrated solar heat; a piece of the true Venice talc, exposed to the focus of Tschirnhaus's large burning lens, presently melted into an untransparent vitreous mass.

I have examined talc with all the mineral acids, and with alkaline lixivia, which some report to have a greater action on it; but without finding that either of them had any action at all; the talc remaining undiminished in weight, and neither the talc or the liquors suffering any sensible alteration. I have calcined it also with sulphur, with sulphur and common salt, with nitre, with sal ammoniac; without any other effect than a little change in its colour. On trying to melt it with twice its weight of borax the talc fell to the bottom, as soon as the borax came into fusion. Alkaline salts, and caustic alcalies taken in four times the weight of the talc, succeeded no better; this refractory earth refusing to unite with them; the salts being afterwards deliquated in the air, the addition of acids occasioned no precipitation, which they must have if the alcalies had taken up in fusion any part of the talc.

Talc is employed, in those places where it is found in any considerable quantity, in compositions for earthen vessels; and by some for tests and cupels. From its smoothness, unctuousity, and brightness, it has been greatly celebrated as a cosmetic; and the chemists have submitted it to a variety of operations, for procuring from it oils, salts, tinctures, magisteries, &c. for that intention. But all their labours have been in vain; and all their preparations sold under the name of talc have either contained nothing of that mineral, or only a fine powder of it.

The pulverization of this mineral is attended with some difficulty. The more brittle pieces may be pulverized pretty easily; but the very tough and flexible scarce at all; nor is the heating the mortar and pestle red-hot, which some recommend, of any advantage. The most commodious method of reducing it into fine powder, is by cautiously filing, or grating it with a fish skin.

Besides the white and greenish talcs already mentioned, there are yellow, red, and black foliaceous concretes distinguished by the same name; but these are in general rather of the gypseous than talky kind. Thus the black talc, mentioned by Hoffman, which laid on burning coals falls into leaves and acquires a golden colour, seems to be a species of lapis specularis. Those of a yellow colour have been called solar talcs, and imagined to be impregnated with a sulphur of gold; which some of the chemists have pretended to extract by spirit of salt or aqua regis. But the yellow tincture which these minerals communicate, and the red sublimate which arises on distilling the solutions, proceeds entirely from ferrugineous matter, common to these with other coloured earths. *Neumann's Chemistry.*

TALENT, *Talentum*, a weight and coin, both very famous among the ancients, but very different in different countries. The value of the talent is very hard to assign in English money, as being used among all the people throughout the East; and its value, and the manner of computation, different among each: A difficulty abundantly shewn by Budæus, in his learned treatise *De Asse*.

There were various kinds of talents, both with regard to weight and to species; the value of these last still increasing, as the metal of which it consisted was purer: though the talent weights all contained the same number of pounds and drams. For as the French have a livre Paris and a livre Tournois, each of which contains alike 20 sols; yet, these compared together, the Paris livre contains 25 sols of the Tournois livre, the Paris sol exceeding that of Tours by one-fifth; so all talent weights were equally 60 minæ, and the mina 100 drachmæ; but the drachma of one place exceeding that of another, there hence arose a difference in the talents.

The Attic drachma, for instance, was 60 Attic oboli, and that of Ægina 10 of the same oboli, whence the Ægean

Ægean talent, computed on the foot of the Attic weight, was 100 minæ; whereas, reckoned on the foot of its own drachmæ, it was no more than 60.

The common Attic talent then, the talent weight we mean, contained 60 Attic minæ, or 62 and a half Attic pounds, or 6000 Attic drachmæ; equal, according to Dr. Arbuthnot's reduction, to 56 pounds 11 ounces English troy-weight. Some authors, as Priscian, mention another Attic talent of 100 minæ; but this is to be understood of ancient minæ, as they stood before Solon, each only worth 75 drachmæ.

The Syrian talent contained 15 Attic minæ; that of Alexandria 96 Attic minæ, or 91 lb. troy. The Babylonian, Persian, and Antiochic talents were the same with the Egyptian. Among the Romans there were two kinds of talents, the little and the great talent: the little was the common talent; and whenever they say, simply, *talentum*, they are to be understood of this: the little talent was 60 minæ, or Roman pounds; the mina, or pound, estimated at 100 drachmæ, or denarii: it was also estimated at 24 great sesterces, which amounted to 60 pounds.

The great talent exceeded the less by one-third part. Budæus computes, that the little talent of silver was worth 75 pounds sterling; and the greater 99 l. 6 s. 8 d. sterling — The greater talent of silver he makes worth 99 l. sterling. — The greater of gold worth 1125 l. sterling.

TALENT, as a species, or money, among the Hebrews, was sometimes used for a gold coin, the same with the shekel of gold, called also stater, and weighing only four drams. The Hebrews reckoned by these talents as we do pounds, &c. Thus a million of gold, or million of talents of gold, among them, was a million of shekels, or nummi; the nummus of gold being the same weight with the shekel, viz. 4 drams.

Yet the Hebrew talent weight of silver, which they called cicar, was equivalent to that of 3000 shekels, or 113 pounds English troy-weight, according to Arbuthnot's computation.

TALES, in law, a word used for a supply of men impannelled on a jury, and not appearing; or upon appearance, being challenged for the plaintiff or defendant, as not indifferent; in which case the judge, upon motion, of course grants a supply to be made by the sheriff, of some persons there present, equal in reputation to those that are impannelled. Where a person has had one tales, he may have another, but not have the latter to contain so many as the former, because the first tales must be under the number of the principal pannel, except in the case of appeal; and in like manner every tales is to be less than other, until the whole number made use of, are persons without exception. There are two kinds of tales, the one de circumstantibus, and the other a decem tales: that of circumstantibus, is, when a full jury does not appear at the nisi prius, or so many are challenged as not to have a full jury; on which motion being made, the judge will grant this tales, which the sheriff immediately returns into court. A decem tales is when a full jury does not appear at a trial at bar, in which case this writ goes out to the sheriff, commanding him to *apponere decem tales*.

TALIO, *Lex Talionis*, a species of punishment in the Mosaic law, whereby an evil is returned similar to that committed against us by another; hence that expression, "Eye for eye, tooth for tooth." This law was at first inserted in the twelve tables amongst the Romans, but afterwards set aside, and a power given to the prætor to fix upon a sum of money for the damage done.

TALISMANS, magical figures cut or engraved with superstitious observations on the characteristics and configurations of the heavens, to which some astrologers have attributed wonderful virtues, particularly that of calling down celestial influences.

The word is pure Arabic; though Menage, after Salmasius, thinks it may come from the Greek, *τελεσμα*, operation, or consecration. Borel says it is Persian, and signifies literally, an engraven constellation. Others derive it *à talamaci literis*, which are mysterious characters, or cyphers used by focerers; thus called from *talamasca*, a phantom, or illusion.

TALLOW, a sort of animal fat melted down and clarified for the use of making candles, &c. See the article **CANDLE**.

TALLOW-TREE, in China, is a tree growing in great plenty in that country, which produces a substance like our tallow, and serving for the same purpose.

It is about the height of a cherry-tree, its leaves in form of a heart, of a deep-shining red colour, and its bark very smooth. Its fruit is inclosed in a kind of pod, or cover like a chestnut, and consists of three round white grains of the size and form of a small nut, each having its peculiar capsula, and within a little stone. This stone is encompassed by a white pulp, which has all the properties of true tallow, both as to consistence, colour, and even smell; and accordingly the Chinese make their candles of it; which would doubtless be as good as those in Europe, if they knew how to purify their vegetable, as well as we do our animal, tallow.

All the preparation they give it, is to melt it down and mix a little oil with it, to make it softer and more pliant. It is true their candles made of it yield a thicker smoke, and a dimmer light, than ours; but those defects are owing in a great measure to the wicks, which are not of cotton, but only a little rod of dry light wood covered with the pith of a rush wound round it; which, being very porous, serves to filtrate the minute parts of the tallow, attracted by the burning stick, which by this means is kept alive.

TALLY, in law, a piece of wood cut in two parts, whereon accounts were antiently kept, by means of notches; one part of the tally being kept by the debtor, and the other by the creditor.

As to the tallies of loans, one part thereof is kept in the Exchequer, and the other part given to particular persons in lieu of an obligation for the monies they have lent to the government on acts of parliament. This last part is called the stock, and the former the counter stock, or counter tail.

Tallies of debt, are a kind of acquittance for debt paid to the king, upon the payment of which every debtor receives one of these tallies; and on carrying the same to the clerk of the Pipe-office, has an acquittance there given him, on parchment, for his full discharge.

Tallies of reward, were an allowance made to sheriffs for such sums as they have cast upon them in their accounts, but cannot levy.

TALMUD, or **THALMUD**, among the Jews, a collection of the doctrines of their religion and morality. It is the *corpus juris*, or body of the laws and customs of the Jews, who esteem it equal to the scriptures themselves.

TALON, in architecture, a kind of moulding, which consists of a cymatium, crowned with a square fillet; frequently found to terminate joiners-work, as those of doors, windows, &c.

TALPA, in surgery, is a tumour generally confined to the head, and appearing as the consequence of the venereal disease. The *talpæ* elevate the skin from the pericranium, and generally denote a foulness of the bone beneath; but the nates are generally seated in the neck.

TALUS, in anatomy, the same with the astragal. See **ASTRAGAL**.

TALUS, or **TALUT**, in architecture, the inclination or slope of a work; as of the outside of a wall, when its thickness is diminished by degrees, as it rises in height to make it the firmer.

TALUS, in fortification. Talus of a bastion, or rampart, is the slope or diminution allowed to such a work, whether it be of earth or stone, the better to support its weight.

The exterior talus of a work, is its slope on the side towards the country; which is always made as little as possible, to prevent the enemy's scalado; unless the earth be bad, and then it is absolutely necessary to allow a considerable talus for its parapet. The interior talus of a work is its slope on the inside towards the place.

TAMARIND, *Tamarindus*, in the materia medica, the fruit of a pretty large tree, growing in Arabia, and in the East and West Indies. The fruit is a pod, somewhat resembling a bean cod, including several hard seeds,

together with a dark-coloured viscid pulp: the East India tamarinds are longer than those of the West, the former containing six or seven seeds each, the latter rarely above three or four: they nevertheless seem both to be the produce of one species of plant. The pulp, with the seeds, connected together by numerous tough strings or fibres, are brought to us freed from the outer shell: the oriental sort is drier and darker-coloured than the occidental, and has more pulp: the former is sometimes preserved without addition, the latter has always an admixture of sugar.

The pulp of tamarinds is an agreeable laxative acid; of common use in inflammatory and putrid disorders, for abating thirst and heat, correcting putrefaction, and loosening the belly. The dose, as a laxative, is two or three drams: an ounce or two prove moderately cathartic. It is an useful addition to the purgative sweets, cassia and manna, increasing their action, and rendering them less liable to produce flatulencies: the resinous cathartics are somewhat weakened by it. Tournefort observes that an essential salt may be obtained from tamarinds, by dissolving the pulp in water, and setting the filtered solution, with some oil upon the surface, in a cellar for several months; that the salt is of a sourish taste, and difficultly dissoluble in water; and that a like salt is sometimes found also naturally concreted on the branches of the tree.

The tamarind tree grows to a very large size in those countries where it is a native, but in England it will not thrive out of a stove, especially in winter. The stem is very large, covered with a brown bark, and divides into many branches at the top, which spread wide every way, and are closely garnished with winged leaves, composed of sixteen or eighteen pair of lobes, without a single one at the end. The lobes are about half an inch long, and a sixth part of an inch broad, of a light green, a little hairy, and sit close to the midrib. The flowers come out from the side of the branches five, six, or more together upon the same foot stalk in loose branches; these are composed of five reddish petals, one of which is reflexed, upward like the standard in some of the butterfly flowers, two others stand on each side like the wings, and the other two are turned downwards.

The plants are preserved in the gardens of those who have conveniency to maintain rare exotic trees and shrubs.

They are easily propagated by sowing their seeds on a hot-bed in the spring; and when the plants are come up, they should be planted each into a separate small pot, filled with light rich earth, and plunged into a hot-bed of tanners bark to bring them forward, observing to water and shade them until they have taken root; and as the earth in the pots appears dry, they must be watered from time to time, and should have air given them in proportion to the warmth of the season and the bed in which they are placed: when the pots in which they are planted, are filled with their roots, the plants should be shifted into pots of a larger size, which must be filled up with rich light earth, and again plunged into the hot-bed, giving them air, as before, according to the warmth of the season; but in very hot weather the glasses should be shaded with mats in the heat of the day, otherwise the sun will be too violent for them through the glasses, nor will the plants thrive, if they are exposed to the open air, even in the warmest season; so that they must be constantly kept in the bark stove both summer and winter, treating them in the same manner as the coffee-tree, with whose culture they will thrive exceedingly well.

TAMBAC, a mixture of gold and copper, which the people of Siam hold more beautiful, and set a greater value on, than gold itself.

TAMBOUR, in architecture, a term applied to the Corinthian and Composite capitals, as bearing some resemblance to a drum, which the French call tambour.

TAMBOUR is also used for a little box of timber-work covered with a ceiling, within the porch of certain churches both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding doors.

TAMBOUR also denotes a round coarse stone, several

of which form the shaft of a column not so high as a diameter.

TAMPION, or **TOMPION**, among gunners, a plug to stop the mouths of cannons, mortars, &c. to keep them clean within.

TAN, the bark of oak, chopped and ground by a tanning mill into a coarse powder to be used in the tanning or dressing skins.

Tan is of great use in gardening: first, by its fermentation, when laid in a body, which is always moderate and of a long duration, which renders it of great service to hot-beds: and, secondly, after it is well rotted, it becomes excellent manure for all sorts of cold stiff land; upon which one load of tan is better than two of rotten dung, and will continue longer in the ground.

The use of tan for hot-beds has not been many years known in England; the first hot-beds of this sort, which were made in England, were at Blackheath, in Kent, about fifty-five years ago: these were designed for raising of orange-trees; but, the use of these hot-beds being but little known at that time, they were made but by two or three persons, who had learned the use of them in Holland and Flanders, where the gardeners seldom made any other hot-beds: but in England there were very few hot-beds made of tanner's bark, before the ananas were introduced into this country, which was in 1719, since which time the use of these hot-beds have been more general; and are now made in all those gardens, where the ananas plants are cultivated, or where there are collections of tender exotic plants preserved: and the gardeners here are now better skilled in making and managing of these hot-beds, than in most other countries; which might render it less necessary to give a full description of them here: but, yet, as there may be some persons in the remote parts of England, who have not had an opportunity of informing themselves of the use of tanners bark for this purpose, I shall insert the shortest and plainest method of making and managing these hot-beds, as they are practised by the most knowing persons, who have long made use of these-hot beds: and, first, I shall begin with the choice of the tan.

The tanners in some parts of England do not grind the bark to reduce it into small pieces, as is commonly practised by the tanners near London; where there is great difference in the size of the bark, some being ground much smaller than the other, according to the different purposes for which it is intended; but in many places the bark is only chopped into large pieces, which renders it very different for the use of hot-beds; for, if the tan is very coarse, it will require a longer time to ferment, than the small tan; but, when it begins to heat, it will require a much greater degree, and will retain the heat a much longer time than the small; therefore, where there is choice, the middling-size tan should be preferred; for it is very difficult to manage an hot-bed when made of the largest tan: the heat of which is often so great, as to scald the roots of plants, if the pots are fully plunged into the bed; and I have known this violent heat continue upwards of two months; so that it has been unsafe to plunge the pots more than half their depth into the tan, till near three months after the beds have been made: therefore, where the persons, who have the care of these beds, do not diligently observe their working, they may in a short time destroy the plants which are placed in the beds: on the other hand, if the tan is very small, it will not retain the heat above a month, or five weeks; and will be rotten and unfit for an hot-bed in a short time; so that, where the middle-sized tan can be procured, it should always be preferred to any other.

The tan should be always such as has been newly taken out of the pits; for if it lies long in the tanner's yard, before it is used, the beds seldom acquire a proper degree of heat; nor do they continue their heat long; so that when it has been more than a fortnight or three weeks out of the pit, it is not so good for use as that which is new. If the tan is very wet it will be proper to spread it abroad for two or three days to drain out the moisture, especially if it is in the autumn or winter season; because, then, as there will be little sun to draw a warmth into the tan, the moisture will prevent the fer-

U u u mentation

mentation, and the beds will remain cold: but, in the summer-season, there is no great danger from the moisture of the tan; the heat of the sun through the glasses will be then so great, as soon to cause a fermentation in the tan.

These tan-beds should always be made in pits, having brick walls round them, and a brick pavement at the bottom, to prevent the earth from mixing with the tan; which will prevent the tan from heating; these pits must not be less than three feet deep, and six feet in width; the length must be in proportion to the number of plants they are to contain: but, if they are not ten feet in length, they will not retain their heat long: for, where there is not a good body of tan, the out-side of the bed will soon lose its heat; so that the plants which are there plunged, will have no benefit of the heat; nor will the middle of these beds retain their heat long; so that they will not answer the purpose for which they are intended.

When the tan is put into the bed, it must not be beaten or trodden down too close; for that will cause it to adhere, and form one solid lump; so that it will not acquire an heat; nor should it be trodden down at the time when the pots are plunged into the beds; to avoid which there should be a board laid cross the bed, which should be supported at each end to prevent its resting on the tan; upon which the person should stand, who plunges the pots; so that the tan will not be pressed down too close. When the tan is quite fresh, and has not been out of the pits long enough to acquire an heat, then the beds will require a fortnight or three weeks time, or sometimes a month, before they will be of a proper temperature of warmth to receive the plants: but, in order to judge of this, there should be three or four sticks thrust down into the tan, about eighteen inches deep, in different parts of the bed; so that by drawing out the sticks, and feeling them at different depths, it will be easy to judge of the temper of the beds; and it will be proper to let a few of these sticks remain in the bed, after the plants are plunged, in order to know the warmth of the tan; which may be better judged of by feeling these sticks, than by drawing out the pots, or plunging the hand in the tan.

When the tan is good, one of these beds will retain a proper degree of heat for near three months; and, when the heat declines, if the tan is forked up, and turned over, and some new tan added to it, the heat will renew again, and will continue two months longer: so that by turning over the tan, and adding some new tan every two months, or thereabout, as the bed is found to decline of its heat, they may be continued one year: but every autumn it will be proper to take out a good quantity of the old tan, and to add as much new to the bed, that the heat of the bed may be kept up in winter; for, if the heat is suffered to decline too much during the cold season, the plants will suffer greatly: to prevent this, there should always be some new tan added to the bed in winter, when the heat is found to decline; but the tan should be laid in a dry place, a week or ten days, to dry, before it is put into the bed; otherwise the moisture will chill the old tan in the bed, and prevent the fermentation: so that unless the tan is turned over again, there will be little or no heat in the beds: which often proves fatal to the plants which are plunged into them: therefore, whoever has the management of these beds, should be very careful to observe constantly the warmth of the tan; since, upon keeping the beds in a due temperature of warmth, the whole success depends; and, where this caution is not taken, it frequently happens, that the ananas plants run into fruit very small, or the plants are infested by insects; both which are occasioned by the growth of the plants being stopped by the decline of the heat of the tan; therefore great regard must be had to that, especially in winter.

The great advantages which these tan-beds have of those which are made of horse-dung, are, the moderate heat which they acquire; for their heat is never so violent as those of horse-dung; and they continue this heat much longer; and, when the heat declines, it may be renewed, by turning the beds over, and mixing some new tan with the old, which cannot be so well done with horse-dung; and likewise the beds will not

produce so great steams, which are often injurious to tender plants; so that these tan-beds are much preferable to those of horse-dung for most purposes.

Tan, when it is well rotted, is also an excellent manure for all cold and stiff lands: and if it is laid upon grass-ground in autumn, that the rains in winter may wash it into the ground, it will greatly improve the grass; but when it is used new, or in the spring of the year, when dry weather comes, it is apt to cause the grass to burn; which has occasioned the disuse of tan in many places; but, if properly used, it will be found an excellent dressing for all stiff lands.

Flowers of TAN.— Flower of tan is a name given by the people employed in the tanning trade to a yellow substance, often found upon old tan, or oak bark broken to pieces, which has been used as tan, and is of no farther service.

The name, however, is very improper; and, though every body conversant in tan-yards must have seen the thing, yet it has always passed as an efflorescence of the bark, till the curious Mr. Marchand enquired more accurately into its nature, and found it to be a plant of itself, wholly different from the matter of the tan; and to which the bark which had been often wetted and dried again, served as a proper matrix. He found it to be more nearly allied to the sponge than to any other genus of plants; and therefore named it "*Spongia fugax, mollis, flava, et amœna in pulvere coriario nascens, soft, beautiful, yellow, fading sponge, growing on tanners bark.*"

It makes its appearance most frequently in the summer months, and is then seen in small tufts of a beautiful yellow colour, on different parts of the old heaps of bark. It appears at first in form of a thin yellow scum, and is of a sort of jelly-like structure; but it every day grows larger and thicker, till it stands above half an inch out from the surface of the bark. As it grows, its surface becomes more and more cavernous and spongy, the pores or holes being of different diameters, and the interstitial matter forming a sort of net-work more or less regular, and often interrupted by irregular prominences in several parts; and, in fine, when the growth is complete, the whole more resembles a sponge, than any other vegetable substance, and is of a deep yellow colour, and considerably thick and tough consistence; there are no roots to be discovered issuing from it; its smell is like to that of rotten wood, and its taste is somewhat styptic. It always appears in the warm months, and always upon such old tan as has begun to ferment, and is in the state in which our gardeners use it for hot-beds. If it happens to stand exposed to the south sun, it is but of short duration; but, if it be in a sheltered place, it will last a considerable time, and often spread itself to a great extent, and make a very beautiful figure for many weeks. *Mem. Acad. Par. 1727.*

TANGENT, in geometry, a right-line which touches a circle but in one point, and consequently, if infinitely produced, could never cut the same.

TANGENT of an Arch, is a right-line drawn perpendicularly from the end of a diameter, passing to one extremity of the arch, and terminated by a right-line drawn from the center, through the other extremity of the arch.—Thus A T, plate CXXV. fig. 3. is the tangent of the arches S A and S D.

Co-TANGENT of an Arch, is the tangent of the complement of that arch.—Thus B G is the co-tangent of the arch S A, or the tangent of the arch S B the complement of S A.

TANGENT of a Curve, is a right-line which only touches the curve in one point, but does not cut it.

Method of drawing TANGENTS to Curves.—The fluxion of the ordinate is to the fluxion of the abscisse, as the ordinate is to the sub-tangent.

Let A C c, plate CXXV. fig. 4. represent a curve, A its vertex, A B the abscisse, B C the ordinate, V C a tangent to the curve in the point C, and V B the sub-tangent. I say, that the ordinate B C is to the sub-tangent V B, as the fluxion of the ordinate B C is to the fluxion of the abscisse A B.

Conceive the ordinate B C to flow uniformly, and move till it come into the place b c, and draw C E parallel to A B.

Gantaler's Cope

It is manifest that CE and cE are in the first ratio of the nascent increments of AB and BC , generated in the first moment of time; for while AB flowed into, or became Ab , BC flowed into or became bC .

Draw Cc subtending the arch Cc , and produce it till it cut the abscissa produced in the point u , then will the triangles ECc and cBu be similar.

And it will be as $cE : EC :: cb : bv$;

That is, as $cE : EC :: cE + Eb : bB + Bu$;

For $cb = cE + Eb$, and $bu = bB + Bu$;

Also, $Eb = CB$, and $Bb = CE$;

Wherefore, $cE : EC :: cE + CB : EC + Bu$.

Let us now imagine the ordinate bC to return back into its former place, and become BC , at which time the right lines cCu and VC will be coincident, the increments $cEEC$ will vanish, and the triangle cEC , in its evanescent form, will be similar to the triangle CBV , and consequently, $cE : EC :: CB : BV$, which was the thing to be demonstrated. Whence it follows, supposing x to represent the abscissa AB of any curve AC , y the ordinate BC , and t the sub-tangent BV , that

$y : x :: y : t$; whence $tj = xy$, and $t = \frac{xy}{y}$; and hence

arises this general rule for drawing of tangents to curves.

1. Find the fluxionary value of the abscissa from the equation expressing the nature of the curve.

2. Multiply the fluxionary value by y , and divide that product by the fluxion of the same ordinate. Or, which is the same thing, in the room of y , in the fluxionary value of the sub-tangent, substitute the fluent itself, and the result, in either way, will be the value of the sub-tangent in the terms of the equation first given. And hence we are taught how to draw a tangent to any point in a curve, the equation, expressing the nature of the curve, being first given.

Let it be required to draw a tangent to a given point in the curve of the common parabola. The equation of this curve being $2px = y^2$ ($2p$ being the latus rectum) we shall have $2p\dot{x} = 2y\dot{y}$, and consequently $\dot{y} = \frac{2p\dot{x}}{y}$; whence

$\frac{y\dot{x}}{\dot{y}}$, or its equal t , becomes $\frac{yy}{p}$, or $2x$: hence it appears that in the common parabola the subtangent is double the abscissa.

Line of TANGENTS, a line usually placed on the sector and Gunter's scale. See **SECTOR**, and **GUNTER'S Scale**.

TANNER, one who dresses hides, &c. by tanning them.

TANNING, the preparing of skins or hides in a pit, with tan and water, after the hair has been first taken off, by putting the skins into lime-water.

Method of TANNING Oxen-hides. The skin being flayed off the carcase, if it is intended to be kept, is salted with sea-salt and alum, or with a coarse kind of salt-petre. If it is not for keeping, the salting is saved, as being of no use but to prevent the hide from corrupting before it can be conveniently carried to the tan-house. Whether the hide has been salted or not, the tanner begins with taking off the horns, the ears, and the tail, after which it is thrown into a running water for about thirty hours, to wash off the blood and other impurities adhering to the inside. This done, it is laid over night in a lime-pit, already used, whence it is taken and left to drain three or four days on the edge of the pit. The first and slightest preparation over, it is retained into a strong lime-pit for two days, then taken out for four days more; and thus for six weeks alternately it is taken out and put in twice a week. At the six weeks end it is put into a fresh pit, where it continues eight days, and is then taken out for so many, and thus alternately for a year or eighteen months, according to the strength of the leather and the weather; for in great heats they put in fresh lime twice a week; and in frost they sometimes do not touch them for three months.

Every fresh lime-pit they throw them into, is stronger and stronger. At the end of four, five, or six weeks, the tanner scrapes off the hair on a wooden leg or horse, with a kind of knife made for that purpose. And after a year or eighteen months, when the hair is perfectly gone, he carries it to a river to wash, pares off the flesh on the leg

with a kind of cutting knife, and rubs it briskly with a sort of whetstone, to take off any remains of flesh or of filth on the side of the hair. The skin is now put into tan, that is, it is covered with tan as it is stretched in the pit, and water is let in upon it; if the skin is strong, five coverings of tan will be required; for weaker, three or four may suffice. When the skin has not been kept long enough in lime, or in the tan-pit, upon cutting it in the middle there appears a whitish streak, called the horn or crudity of the skin, and it is this crudity that is the reason why the soles of shoes, boots, &c. stretch so easily and take water. When the hides are sufficiently tanned, they are taken out of the pit to be dried, by hanging them in the air; then the tan is cleared off them, and they are put into a place neither too dry nor too moist; they are there well stretched over one another with weights a-top, to keep them tight and strait; and in this condition are sold under the denomination of bend-leather. This is the method of tanning bullocks or oxen-hides. Cows, calves, and horses skins are tanned much after the same manner of those of oxen, except that they are only kept four months in the lime pit, and that before they be put in the tan, there is a preparation required thus: cold water is poured into a wooden vat, or tub, wherein the skins are put, which are kept stirring while some other water is warming in a kettle; and as soon as that water is little more than lukewarm, it is poured gently into the vat, and upon this is cast a basket of tan; during which time the skins are still kept turning, that the water and tan may not scorch them. After an hour they are taken out and cast for a day into cold water, then returned to the former vat and the same water they had been in before, and here they are left for eight days: which expired, they are put into the tan-pit, and three coverings of tan given them; the first of which lasts five weeks, the second six, and the third two months.

The operation of tanning is performed, on leather, better in the West Indies than in England. They use three sorts of bark, the mangrove bark, the olive-bark, and another; and the whole business is so soon done, that a hide delivered to them is in six weeks ready to be worked into shoes, though they bestow less labour than we do. *Phil. Trans.* N^o. 36.

Every part of the oak-tree, of what age or growth soever, is fit for the tanners use, and all oaken coppice-wood, of any age or size, being cut and procured in barking-time, will tan all sort of leather, at least as well as the bark alone. When this material is got at the proper season, it must be very well dried in the sun more than the bark alone; thence it is to be cut up, and preserved in a covered place for use.

When it is to be used, the greater wood must be first cleft small, to fit it for the beating and cutting engine; and the smaller must be put into the engine as it is. Which done, it must be again dried on a kiln, and after that ground in the same manner that the tanners grind their bark. Such wood as is to be used presently after it is gotten, will require the better and the more drying upon the kiln; and, if this is omitted, it will blacken and spoil all the leather it is to be used about. Where oak is scarce, black-thorn will tolerably well supply its place, and, where that is not to be had in sufficient plenty, the white-thorn will do. *Phil. Trans.* N^o. 108.

Birch also, being ordered in the same manner with oak, is fit for some uses in tanning, particularly it does very well for tanning of shoe-sole leather. All these ingredients will tan much better than bark alone, and that with much less charge; so that this discovery may very well save the felling of trees when the bark is wanted, at a season when the sap is up, which, when it is done, causes the outsidings of the trees to rot and grow worm-eaten; whereas, if the trees had been felled in winter, when the sap is down, they would have been almost all heart, as the people express it, and not subject to worms. The manner of using the wood with the bark, in tanning, will also increase the value of underwoods very considerably. *Phil. Trans.* N^o. 105.

The engine necessary for cutting the wood consists of a long square wooden block, and some pieces of iron to be

be fastened on, and used about it, viz. a hammer, an anvil, and iron holding the wood to be bruised and cut, and a knife to cut it. The whole is a very simple and cheap machine, and is described at large, and figured in the abovementioned number in the *Philosophical Transactions*.

By Mr. de Buffon's experiments upon different skins, it was found that a decoction of young oak wood succeeded perfectly well in tanning sheep and calves skins, but did not do equally well for ox, and the other harder skins. This, however, he imagines might be only for want of knowing the best method of using the wood. And, certainly, these trials deserve to be farther prosecuted; since the small branches of the oak, which are of little value, might be thus made to supply the place of a much dearer commodity, the bark; and, as in many trees, the bark of the young branches is found to be of greatly more virtue than that of the larger branches, or the trunk, the use of these small boughs, bark and all, might very probably be found to answer to all the effects of the bark, of the larger kind alone. *Memoires Acad. Scien. Par. 1736.*

The saw-dust of the oak has also been found, by several experiments made before the Society of Arts, &c. to answer full as well as the bark itself.

In the year 1729, a paper was printed and addressed to the House of Commons in Ireland, containing an expeditious and cheap method of tanning without bark; upon which the house voted an immediate reward to the proposer, Mr. William Maple, and promised him further encouragement. The substance of the above paper was as follows.

Oak bark, by its insinuating into the pores, and incorporating with the substance of the hide, produces a firmness, strength, and consolidation of the parts: it must therefore stand to reason, that other vegetable materials, possessing the same apparent qualities, may probably produce the like effects, when applied to the same use.

Mr. Maple observes that tormentil and cinquefoil roots are ranged in the same medical class with oak bark, and have the same apparent qualities, especially the first, in a more eminent degree than bark itself.

In the trials made in Ireland in this affair, by Mr. Maple and his friends, they were found to answer beyond expectation. The cinquefoil, it is true, did not give so good a colour as the tormentil, but in other respects tanned the hides well.

The tormentil, however, made ample amends; for in all respects, as to colour, bloom, substance, solidity, and weight, in the tanned hide, it completely answered, and in much less time than when bark, even of the best kind or growth, was used.

This assertion is by no means founded on a single experiment, on which little dependence can be had: on the contrary, it is grounded on several years experience, and confirmed by the opinion and testimony of several tanners, and others, who were supposed (by the committee of the House of Commons of Ireland, to whom the consideration of the affair was referred by the house) to be good judges in a matter of this nature.

It may not be amiss, to lay down a state of what passed before the above committee, when this affair was coolly, impartially, and carefully enquired into, and the specimens produced by Mr. Maple examined by all present with due attention.

The committee were pleased, for their greater satisfaction, to summon a great number of tanners, curriers, shoemakers, and others, to attend to give their testimony in relation to the several specimens and proofs that were to be laid before them.

In respect to the goodness of the leather so tanned, the following specimens were exhibited.

Number I. A calf's skin from the ooze.

Numb. II. A calf's skin uncurried.

Numb. III. A calf's skin curried.

(Each of these, when tanned and dried, weighing about three pounds.)

Numb. IV. A calf's skin, very strong and large, when tanned and dried weighing about six pounds.

Numb. V. Seven or eight pair of soles, of a calf's skin raised.

Numb. VI. A bend of bullock's hide for harness.

These were all proved, by Thomas Cooly and Patrick Shale, to be tanned without bark, and with the roots.

Mr. Henderson, master of the tanners, said he was diffident of the goodness of the specimens; but that he should have been thoroughly satisfied, had he known how the leathers had proved, if worn by some porters or chairmen; that the colour of Number II. or III. was not so good as some tanned with bark, producing a calf's skin curried, to compare with them; but did own all the specimens were thoroughly struck, and well tanned; that if they were in the shop, intermixed with skins tanned by bark, he could not distinguish them; and that what tanned Numb. V. and VI. would tan (time and quantity allowed) the thickest bullock's hide.

Mr. Dobson, tanner, affirmed the specimens were not well tanned, because they did not come up to the colour of the skin produced by Mr. Henderson; but in other respects, the leather appeared to be as good, in their respective kinds, as any tanned with bark.

Mr. Nicholas Gibton, master of the curriers, affirmed, that the skin produced by Mr. Henderson was of an extraordinary colour; that there were not ten such in Dublin; that the difference in colour was but very small, and in regard even to colour, he would chuse those tanned by the vegetables as soon as Mr. Henderson's skin; that all the specimens appeared to be very well tanned; and that he could in no wise distinguish them from bark tannage.

Mr. Devereux, currier, being sent out, returned and produced two calves skins tanned by the bark, which he took indifferently, and without choosing, from the next currier's shop. They were allowed by all to be of a general, or common colour, and, being compared, were much exceeded by the specimens, and particularly as to colour.

Mr. Edmund Shield, currier, said he never saw better tanned leather than the specimens; that their colour was very good; and that what tanned Numb. V. would tan any hide whatever.

Mr. Brookfield, tanner, reported, the specimens exhibited were well tanned, and thoroughly struck; that neither he, or any other, could distinguish them from bark tannage; and what tanned Numb. V. could not fail in any tannage.

Mr. Veckers, tanner, allowed the specimens to be very well tanned, and gave it, as his opinion, that what tanned Numb. V. and VI. would tan the thickest sole-leather.

Mr. John Gades, shoemaker, after giving his testimony that all the specimens appear to be exceedingly well tanned, produced a shoe made by him of the leather of this tannage, affirming the leather wrought very well; and that the soles exhibited, under the hammer, all the signs of extraordinary leather.

Mr. Ellis, shoemaker, reported, the specimens were very well tanned; that leather, either dead, or highly tanned, would never carry so beautiful a colour as leather otherwise tanned; that the sole-leather appeared to be very well tanned; and that, in his opinion, this tannage would, in every respect, answer the same end, or intentions, as bark tannage.

Mr. King, shoemaker, said all the specimens were effectually tanned.

Mr. Richard Norris, shoemaker, produced a sole of this tannage, beaten; asserting he never saw so good a sole of raised calf's skin; that it beat firm, solid, and without spreading, or suziness, which are the distinguishing characters of good sole-leather. He desired it might be cut in several places, that the closeness and firmness might be viewed; which accordingly was done, and answering expectation, was approved.

There were a great many other tanners, curriers, and shoemakers, who were of the same opinion: but, considering their testimonies would be but so many repetitions, they need not be recited.

Dr. Richard Hefham, professor of natural philosophy in Trinity College, said Mr. Maple had communicated to him what was used in this tannage, which appeared to him to be well adapted to tanning, and would not fail to give a sufficient strength and rigidity to the fibres; adding, he wore a pair of shoes, the upper leathers of this tannage, daily for four months, and, being

ing willing to try the utmost of the leather, he had new soles put to them; that since, he had worn them about a month; shewing them without any cracks or defect.

Patrick Carrol produced two slips of curried calf-skin, the one tanned by bark, the other by the roots, each three tenths of an inch broad, and ten inches long. The first was the thickest, and weighed a tenth part more than the other. He said he was present, with several others, when it broke, by a weight of one hundred and twenty-nine pounds being hung to it; that the slip of this new tannage being tried with the same circumstances, bore twenty-nine pounds more than the hundred and twenty-nine pounds, before it either yielded or broke.

In respect to time.

That the specimens, Numb. I. II. and III. were tanned in five weeks, Numb. IV. in nine weeks, Numb. V. in four months, without any hurry extraordinary, or illegal methods, was proved by Mr. Thomas Cooley, and Patrick Shale. On the other side it appeared, that, in tanning with bark, from three to five months were required for calves skins; from seven to nine were requisite for soles of raised calves skins; and from ten to thirteen months for bullocks hides, which, by this tannage, may be effected in nine or ten.

In regard to cheapness, part of the roots used were purchased at three farthings the pound; but afterwards Mr. Maple, being willing to engage the privacy of the gatherer, gave a penny: they lose about a third in drying. Allowing these as facts, and taking it at the dearest, less than five shillings worth of roots will go farther than a barrel, or four bushels, of the best bark.

TANNING ENGINES, machines used by tanners for beating, cutting, and grinding tan, or the materials used in tanning. See **TAN**, and the preceding article.

The machine for cutting tan, as represented in plate CXXV. *fig. 4* and 5. consists of a long square wooden block, which is best of oak or elm; and of some pieces of iron to be fastened on it, and used about it, viz. an anvil, a hammer, an iron holding the wood to be bruised and cut, and a knife. *AB*, *fig. 4*. is the length of the block, being about four feet; *CD* the breadth, which is fifteen or sixteen inches; *EF* the depth, eight or ten inches; *GHIK* a square cavity to receive a plate of iron, serving for an anvil to beat and bruise the tanning materials upon; this is to be about four inches deep, nine inches broad, and twelve inches long; *LMNO* the iron for claspings and holding fast the materials to be bruised and cut; which must lie cross the engine, about the middle of the said piece of timber, and may be about three inches broad; *PQ* are two hooks at one end of it, which are turned upwards, and must be hooked into the loops of the two hinges that are let in and fastened to the sides of the engine. *RS*, in such a manner that this clasping-piece may be a little raised for putting the tanning materials under it. At the side *T*, (*fig. 5*.) is a single hook turned also upwards, to hang a weight upon it, whilst the stuff is a bruising by the anvil, or a cutting by the knife. The button in *fig. 4*. serves to take up this piece by; *aaaa* on the other side of the block, *fig. 5*. are the places for the four feet of the engine, which are to be of a convenient height to work upon it. *b* (*fig. 6*.) is the hammer for beating and bruising the stuff, which may be of six pounds weight, and the head about three inches square, to work with both hands; but for one hand, it may be made of three pounds weight, and the head about two inches square: the surface of one end of these hammers should be smooth, but that of the other indented. *cd*, *fig. 4*. the knife for cutting the bruised stuff, which must be eight or nine inches long, and near as much in breadth, made like a tobacco-knife, with a handle, and fastened to the block at the two opposite sides, that are to be hollowed, with two grooves, *efgh*, *fig. 5*. and *iklm*, *fig. 4*. with two pieces of iron fitted in the grooves, to hold and guide the knife in cutting. *nopq*, *fig. 4*. is to be fastened to the end of the knife *c*, by a pin *r*, passing through three holes; and this end is to be screwed into the groove *efgh*, *fig. 5*. by a couple of screw-pins; the other piece, *stuxyz*, *fig. 4*. being forked in, is to receive the other end of the knife *d*, and the solid square part thereof, *IKLM*, is to be fastened in the groove under it by two iron-plates *aaee*, under

which it must run in the said groove so as to be slipped out from under it, and laid by when the machine is not used, when also the piece at the other end may be unscrewed and laid up. The long squares upon one end of the block, viz. 5, 6, 7, 8, *fig. 4*. are two iron plates, to be fastened where the knife, moving in a fit cavity, is to cut the bruised stuff between them; and of these plates that which lies next the end is to be laid a little lower, the block being there pared accordingly, that so the stuff may fall off from the end of the machine the quicker, as the left-hand supplies the bruised materials, whilst the right-hand cuts them. Let the hollow place where the knife cuts be as near as possible, only large enough for the knife to rise and fall easily; and let the block be hollowed under the cutting-hole, and sloped off at that end, for the stuff to fall off, as it is cut by the knife.

The stuff being cut small by the engine, is to be well dried again on a kiln, and then ground into a coarse powder upon the mill, being a large round wooden trough with a pretty large stone set on edge in it, and turned round by a horse, as represented *fig. 7*.

TANTALUS'S CUP, in hydraulics, a siphon so adapted to a cup, that the long leg may go down through the bottom of the cup.

This bended siphon is called Tantalus's cup, from the resemblance of the experiment made with an image in the glass, representing Tantalus in the fable, fixed up in the middle of the cup with a siphon concealed in his body, beginning in the bottom of his feet, and ascending to the upper part of his breast; there it makes a turn, and descends through the other leg, on which he stands; and from thence through the bottom of the cup, where it runs out, and causes the water to subside in the cup: as soon as it rises to the height of the siphon, or to the chin of the image, which is above *Ss*, (plate CXXV. *fig. 8*.) the water will begin to run through the siphon concealed in the figure, till the cup is emptied in the manner explained under Siphon, and represented more distinctly in *fig. 9*.

Sometimes the Tantalus's cup is made without a figure fixed in it, as *fig. 10*. where the water being up at *Ss*, the cup does not run; but as soon as the figure, or an apple, or orange, &c. is thrown in, the water begins to run out at the foot of the cup, and does not cease till the whole cup is empty. This happens because the body thrown into the cup, raises the water's surface from *Ss* to *BC*, where being above the upper end *S* of the pipe *SP* concealed in the handle, which thereby is made a siphon, the water which is come into the handle at *O* runs into the middle pipe at *S*, and so out at *P*, under the foot, so long as there is any water above *O*.

TANTAMOUNT, something that amounts, or is equivalent, to some other.

TAPER, **TAPERING**, is understood of a piece of timber, or the like, when broad at one end gradually diminishing to the other, as is the case in pyramids, cones, &c.

TAPER BOARD, is applied to a piece of ordnance when it is wider at the mouth than towards the breech.

TAPER also denotes a kind of tall wax candle placed in a candlestick, and burnt at funeral processions, and in other church solemnities. Tapers are made of different sizes; in some places, as Italy, &c. they are conical or taper; both kinds are pierced at the bottom for a kind of pin in the candlestick to enter. For the method of making tapers, both by the ladle and by the hand, see the articles **CANDLE** and **FLAMBEAU**.

Paschal **TAPER**, among the Romanists, a large taper whereon the deacon applies five bits of frankincense in holes made for the purpose in form of a cross, and which he lights with new fire in the ceremony of Easter-Sunday.

TAPESTRY, or **TAPISTRY**, a curious kind of manufacture, serving to adorn a chamber or other apartment, by covering or lining the walls thereof. It is a kind of woven hangings of wool and silk, frequently raised and enriched with gold and silver, representing figures of men, animals, landscapes, histories, &c.

The invention of tapestry seems to have come to us from the Levant; and this seems the more probable, in that the workmen concerned in it were called, at

least in France, Sarrafins, or Sarrafinois. It is supposed that the English and Flemish, who were the first that excelled in making tapestry, might bring the art with them from some of the croisades, or expeditions against the Saracens. Be this as it will, it is certain that these two nations, especially the English, were the first who set on foot this noble and rich manufacture in Europe, now one of the finest ornaments of palaces, churches, &c. and therefore if they may not be allowed the inventors, they have at least the glory of being the restorers of this so curious and admirable an art, as gives a kind of life to wools and silks, in no respect inferior to the paintings of the best masters.

Tapestry-work is distinguished by the workmen into two kinds, viz. that of high, and that of low warp; though the difference is rather in the manner of working than in the work itself; which is in effect the same in both; only the looms, and consequently the warps, are differently situated; those of the low warp being placed flat and parallel to the horizon, and those, on the contrary, of the high warp erected perpendicularly. The English anciently excelled all the world in the tapestry of the high warp, and they still retain their former reputation, though with some little change: their low warps are still admired; but, as for the high ones, they are quite laid aside by the French. The French have three considerable tapestry-manufactures besides that of the Gobelins; the first at Aubusson in Auvergne, the second is at Felletin in the Upper Marche, and the third at Beauvais. They were all equally established for the high and the low warp; but they have all laid aside the high warp, except the Gobelins. There are admirable low warps in Flanders, generally exceeding those of France; the chief and almost only Flemish manufactures are at Brussels, Antwerp, Oudenard, Lisle, Tournay, Bruges, and Valenciennes.

The usual widths of tapestries are from two ells to three ells Paris measure.

The Manufacture of TAPESTRY of the high warp.—

The loom, whereon it is wrought, is placed perpendicularly: it consists of four principal pieces; two long planks or cheeks of wood, and two thick rollers or beams. The planks are set upright, and the beams across them, one at the top, and the other at the bottom, or about a foot distance from the ground. They have each their trunnions, by which they are suspended on the planks, and are turned with bars. In each roller is a groove from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which is a kind of worsted, or twisted woollen thread, is wound on the upper roller; and the work, as fast as wove, is wound on the lower. Within side the planks, which are seven or eight feet high, fourteen or fifteen inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at one end, serving to sustain the coat-stave; these pieces of iron have also holes pierced, by putting a pin, in which the stave is drawn nearer or set farther off; and thus the coats or threads are stretched or loosened at pleasure. The coat-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the coats or threads, which make the threads of the warp cross each other. It has much the same effect here, as the spring-stave and treadles have in the common loom. The coats are little threads fastened to each thread of the warp with a kind of sliding knot, which forms a sort of mask or ring. They serve to keep the warp open for the passage of broaches wound with silks, woollens, or other matters used in the piece of tapestry. In the last place, there are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing them across: and, that the threads thus crossed may retain their proper situation, a packthread is run among the threads, above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does, is to draw on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry;

which is done by applying cartoons, made from the painting he intends to copy, to the side that is to be the wrong side of the piece, and then, with a black-lead pencil, following and tracing out the contours thereof on the thread of the right-side, so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workmen, and wound on a long staff from which a piece is unrolled from time to time, as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the woof within the threads of the warp; these are a broach, a reed, and an iron-needle.

The broach is made of a hard wood, seven or eight inches long, and two thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, gold, or silver to be used in the work, being wound on it.

The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremity of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only bigger and longer. Its use is to press close the wool and silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works as it were blind-fold, seeing nothing of what he does, and being obliged to quit his post, and go to the other side of the loom, whenever he would view and examine the piece, to correct it with his pressing needle. To put silk, &c. in the warp, he first turns and looks at the design, then, taking a broach full of the proper colour, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the coats or threads, fastened to the staff; this he repeats every time he is to change his colour. Having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have, in order to reform the contours with his needle, if there be occasion. As the work advances, it is rolled upon the lower beam, and they unroll as much warp from the upper beam, as suffices them to continue the piece: the like they do of the design behind them. When the pieces are wide, several workmen may be employed at once.

We have but two things to add: the first is, that the high-warp tapestry goes on much more slowly than the low-warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this, that in the low-warp there is a red fillet, about one twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

But, for the satisfaction of our readers, we shall here present them with a representation of the loom for the manufacture of tapestry of the high-warp, or that in a situation perpendicular to the horizon. See plate CXXVI. fig. 1, where 1, 1, represent the loom posts, or the thick planks, which support the rollers. 2. The rollers; the upper end holds the chain, the lower holds the tapestry, which is rolled upon it, according as the work goes forward: the threads are fastened at their ends to a dweet, or thick rod, which is lodged in a groove made on each roller. 3. The two tantoes; one called the great tantoe, for turning the upper roller; the other the little tantoe, for turning the lower roller. 4. The pole of the leishes, which runs quite across the chain, takes up all the leishes, and brings them to the workman's hand. These leishes are little strings, tied by a slip-knot to each thread of the chain, to be raised up according as the chain sinks down; they serve to draw the particular thread which the weaver wants: he holds the thread separate from the rest, and passes a spindle of such a woof and colour as he thinks proper; then he lets the spindle hang down, and hinders the thread from running off, by a slip knot. After having taken one or two threads of the forepart of the chain by another leish, he

brings the threads of the opposite side to him. By this alternative work he constantly makes them cross one another, to take in and secure the woof. In order to distinguish the threads of both sides, he is assisted by the cross rod, which is put between two rows of threads.

5. A long tract of dots formed by the ends of the leishes, which take hold of the leishes of the chain by a slip-knot; and on the other hand encompass the pole of the leishes. 6. The cross-rod. 7. A little chain, each loop of which contains four or five threads of the warp, and keeps them perpendicular. 8. An iron-hook, to support the pole of the leishes. 9, 9, 9. The broacher-quill, to pass the threads of the woof, which is wound on it. 10. The comb, to strike in the work. 11. The end of the dweet let into the roller, in a groove.

When the chain is mounted, the draughtsman traces the principal out-lines of the picture, which is to be wrought, with black chalk, on the fore and back side of the chain. The weaver in the upright way having prepared a good stock of quills, filled with threads of all colours, goes to work, placed on the back part, as in the flat way, or in the manufacture of the low-warp. He has behind him his drawings, on which he frequently looks, that he may from time to time see how his work succeeds on the right or fore-side, which the other cannot do.

The Manufacture of TAPESTRY of the Low-warp. The loom or frame wherein the low-warp is wrought, is much like that of the weavers; the principal parts thereof (*fig. 2.*) are two strong pieces of wood, forming the sides of the loom, and bearing a beam or roller at each end; they are sustained at bottom with other long pieces of wood, in manner of tressels; and, to keep them the firmer, are likewise fastened to the floor, with a kind of buttresses, which prevent any shaking, though there are sometimes four or five workmen leaning on the beam at once. The rollers have each their trunnions, by which they are sustained; they are turned by large iron-pins, three feet long. Along each beam runs a groove, in which is placed the wick, a piece of wood above two inches diameter, and almost the length of the roller. This piece fills the groove intirely, and is fastened therein, from space to space, by wooden-pins. To the two wicks are fastened the two extremities of the warp, which is wound on the further roller, and the work, as it advances, on the nearer. Across the two sides, almost in the middle of the loom, passes a wooden bar, which sustains little pieces of wood, not unlike the beam of a ballance: to these pieces are fastened strings, which bear certain spring staves, wherewith the workman, by means of two treddles under the loom, on which he sets his feet, gives a motion to the coats, and makes the threads of the warp rise and fall alternately. Each loom has more or fewer of these spring-staves, and each staff more or fewer coats, as the tapestry consists of more or fewer threads. The design or painting the tapestry-man is to follow, is placed underneath the warp, where it is sustained from space to space with strings, by which the design is brought nearer to the warp. The loom being mounted, there are two instruments used in working of it, viz. the reed and the flute.

The flute does the office of the weaver's shuttle: it is made of a hard polished wood, three or four lines thick at the ends, and somewhat more in the middle, and three or four inches long. On it are wound the silks, or other matters, to be used as the woof of the tapestry, represented. The comb, or reed, is of wood or ivory: it has usually teeth on both sides; it is about an inch thick in the middle, but diminishes each way to the extremity of the teeth; this serves to beat the threads of the woof close to each other, as fast as the workman has passed and placed them, with his flute, among the threads of the warp; as represented at 10, *fig. 1.*

The workman is seated on a bench before the loom, with his breast against the beam, only a cushion or pillow between them; and in this posture separating with his fingers the threads of the warp, that he may see the design underneath; and taking a flute, wound with the proper colour, he fastens it among the threads, after having raised or lowered them, by means of the treddles, moving the spring staves and coats.

Lastly, to press and close the threads of the silk or yarn, &c. thus placed, he strikes each course, i. e. what the flute leaves in its passing and coming back again, with the reed.

That which is very remarkable in the manufacture of the low-warp, and which is common to it with the high, is, that it is all wrought on the wrong side; so that the workman cannot see the right side of his tapestry, until the piece is finished, and taken out of the loom.

TAPLINGS, in the English salt-works, the name given to certain bars of iron, which support the bottom of the pan in which the brine is boiled.

These pans are very large, and cover a wide furnace; but as their width would make them apt to bend in the middle, which would spoil the working of the salt, there is a sort of wall made of brick carried along the middle of the furnace, and on the top of this are placed these taplings; they are about eight inches high, and from four to six in thickness, being smallest at the top. These are placed at about three foot distance one from another, and the wall which supports them, and which is called the midfeather, is broad at the base, and so narrow at the top, as barely to give room for the bases of the taplings.

TAPPING, in general, the act of piercing an hole in a vessel, and applying a tube or cannula in the aperture, for the commodious drawing off the liquors contained therein.

Tapping, in agriculture, is the making an incision in the bark of a tree, and letting out the juice. To tap a tree at the root, is to open it round about the root. In the tapping of trees, the juice taken in from the earth, ascends from the root; and, after it is concocted and assimilated in the branches, &c. it descends, like a liquor in an alembic, to the orifice or incision, where it issues out. One of the most effectual ways of tapping, so as to obtain the greatest quantity of sap, and that in the shortest time, is not only to pierce the bark, or to cut the body of the tree almost to the pith with a chissel, as some have directed, but to bore through all the circles on both sides the pith, leaving only the outermost circle and the bark on the north-east side unpierced. This hole is to be bored sloping upwards, as large as the largest auger will make; and that also through, and under a large arm near the ground; and thus it will not need any stone to keep open the orifice, nor tap to direct the sap into the receiver. This way the tree will, in a short time, afford liquor enough to brew withal: and with some of this sweet sap, one bushel of malt is said to make as good ale as four bushels of malt with ordinary water. The large maple, called the sycamore, is said to yield the best brewing sap, its juice being very sweet and wholesome. It is affirmed that the liquor which may be drawn from a birch, in the spring-time, is equal to the whole weight of the tree, branches, root, and all together.

To preserve the sap for brewing, insolate it by a constant exposure to the sun, in proper vessels, till the rest be gathered and ready, otherwise it will contract an acidity. When there is enough, put into it as much very thin cut and hard-toasted rye-bread, as will serve to ferment it; and when it works, take out the bread, and bottle up the liquor. A few cloves in each vessel that receives the sap, as it oozes from the tree, will also preserve it a twelve-month.

TAPPING, in surgery. See the article **PARACENTESIS**.

TAPUYERS, and **TAPINAMBES**, two numerous tribes which the Portuguese found in Brasil, in South America, when they planted that country.

TAR, a thick, black, resinous, very adhesive juice, melted out by fire from old pines and fir-trees. The trees, cut in pieces, are inclosed in a large oven, which being heated by a fire on the out-side, or the wood itself kindled and smothered, the juice runs off by a canal at the bottom.

Tar differs from the turpentine or native resinous juice of the trees in having received a disagreeable empyreumatic impression from the fire; and in containing, along with the pungent bitter terebinthinate matter, a portion of the acid which is extricated from the wood by the heat, and likewise of its gummy or mucilaginous matter.

By

By the mediation of these principles, a part of the terebinthinate oil and resin becomes dissoluble in watery liquors, which extract little or nothing from the purer turpentine.

Water impregnated with the more soluble parts of tar has been recommended as a remedy for almost all diseases. The proportions that have been commonly followed are, two pounds of tar to a gallon of water; which are to be well stirred together, then suffered to settle for two days, and the clear liquor poured off for use. It is observed, "That tar-water, when right, is not paler than French, nor deeper-coloured than Spanish white wine, and full as clear: if there be not a spirit very sensibly perceived in drinking, the tar-water is not good. It may be drank either cold or warm. As to the quantity, in common chronical indispositions a pint a day may suffice, taken on an empty stomach, at two or four times: more may be taken by strong stomachs. But those who labour under great and inveterate maladies, must drink a greater quantity, at least a quart every twenty-four hours. In acute cases, it must be drank in bed warm, and in great quantity, the fever still enabling the patient to drink, perhaps a pint every hour." Though this medicine is undoubtedly very far inferior to the character that has been given of it, it is apparently capable of answering important purposes, as a deobstruent balsamic solution, moderately warm and stimulating. It sensibly raises the pulse, and increases either perspiration or the grosser evacuations; and we are informed of some late instances of its good effects in disorders of the leprous kind.

Some have imagined the acid to be the principle that gives virtue to tar-water, and hence have endeavoured to introduce, instead of the infusion, an acid spirit extracted from tar by distillation. But the effects of this, as of other acids, are opposite to those experienced from tar-water; nor does the acid of tar differ from that which is extricated by fire from all kinds of recent wood. Tar-water, distilled, yields a liquor very considerably impregnated with its flavour, though more grateful than the infusion itself both in smell and taste; there remains a light, spongy, blackish substance, not acid but bitter, partially dissoluble again in water.

This juice is sometimes given also in substance, mixed with so much powdered liquorice, or other like powdery matters, as is sufficient to render it of a due consistence for being formed into pills. An ointment, made by melting it with an equal weight of mutton-suet, and straining the mixture whilst hot, is sometimes used as a digestive, and said to be particularly serviceable against scorbutic and other cutaneous eruptions.

On inspissating tar, or boiling it down to dryness without addition, it gives over an acid liquor in considerable quantity, and an ethereal oil of the same general nature with that of turpentine, but impregnated with the empyreumatic flavour of the tar. The solid residuum is the common pitch. This is less pungent and less bitter than the liquid tar, and is used only in some external applications, as a warm adhesive resinous substance. Neumann observes, that when melted with oils, resins, and fats, into ointments and plasters, the pitch is greatly disposed to separate and precipitate.

Tar is likewise used for coating and caulking ships, and many other intentions at sea.

TAR-WATER.—In some parts of America, tar-water is made by putting a quart of cold water to a quart of tar, and stirring them well together in a vessel, which is left standing till the tar sinks to the bottom. A glass of clear water, being poured off for a draught, is replaced by the same quantity of fresh water, the vessel being shaken, and left to stand as before. And this is repeated for every glass, so long as the tar continues to impregnate the water sufficiently, which will appear by the smell and taste.

But, as this method produces tar-water of different degrees of strength, Bishop Berkley says, he chuses to make it in the following manner: pour a gallon of cold water on a quart of tar, and stir and mix them thoroughly with a ladle or flat stick, for the space of three or four minutes; after which the vessel must stand eight and forty hours, that the tar may have time to subside; when

the clear water is to be poured off, and kept for use, no more being made from the same tar, which may still serve for common purposes.

It has been found, that several persons infected with cutaneous eruptions and ulcers were immediately relieved, and soon after cured, by the use of this medicine. It is said, that, even in the foulest distempers, it proved much more successful than salivations and wood-drinks had done. It also succeeded, beyond expectation, in a tedious and painful ulceration of the bowels, in a consumptive cough, and, as appeared by expectorated pus, an ulcer in the lungs, in a pleurisy and peripneumony. And, when a person who had been for some years subject to erysipelous fevers, perceived the usual forerunning symptoms to come on, the drinking of tar-water prevented the erysipelas.

Tar-water cures indigestion, and gives a good appetite. It is an excellent medicine in an asthma; it imparts a kindly warmth and quick circulation to the juices, without heating, and is therefore useful, not only as a pectoral and balsamic, but also as a powerful and safe deobstruent in cachectic and hysterical cases. As it is both healing and diuretic, it is very good for the gravel. The bishop says, he believes it to be of great use in a dropsy, having known it cure a very bad anasarca in a person whose thirst, though very extraordinary, was in a short time removed by the drinking of tar-water. It may likewise be safely used in inflammatory cases; and, in fact, hath been found an admirable febrifuge, at once the safest cooler and cordial.

To sailors, and all sea-faring persons, who are subject to scorbutic disorders, and putrid fevers, especially in long southern voyages, he is persuaded this tar-water would be very beneficial.

It is to be observed, that tar-water should not be made in unglazed earthen vessels, these being apt to communicate a nauseous sweetness to the water.

The same ingenious author recommends tar-water in the plague, and for the distemper among the horned cattle; with what success must be left to experience.

TARANTISMUS, in medicine, the disease or affection of those bit by the tarantula.

TARANTULA, in the history of insects, a species of araneus, with an oval hairy body and thick legs.

This is one of the large spiders, but is not the very largest known: its body is three quarters of an inch long, and of the thickness of one's little finger; it is usually of an olive brown, variegated with a dusky colour; but in this it varies greatly: it is covered with a short and soft down, or hairiness; the points of its forceps are very fine and sharp: this species is a native of Apulia.

As to the effects of the poison they convey into the wound they make, there seems yet room for much explanation about it. We are told, that in the summer months, especially when the heats are greatest, as in the dog-days, the tarantula, creeping among the corn in the fields, bites the mowers and passengers: that in the winter it lurks in holes, and is scarcely seen; and that if it bites then, it is not so venomous, neither does it induce any ill symptoms: but in hot-weather, according to Dr. Mead, although the pain of its bite is at first no greater than what is caused by the sting of a bee, yet the part is quickly after discoloured with a livid, black, or yellowish circle, and raised to an inflamed swelling; the patient within a few hours is seized with a violent sickness, difficulty of breathing, universal faintness, and sometimes trembling, with a weakness in the head; and on being asked his ailment, with a tremulous voice, and melancholy look, points to his breast, as if the heart was most affected: the patient grows by degrees more melancholy, stupid, and strangely timorous, and in a short time expires, unless music is called to his assistance, which alone, without the help of medicines, is said to perform the cure, the usual alexipharmics and cordial medicines being of no service: for at the first sound of the musical instrument, although the sick lie as it were in an apoplectic fit, they begin by degrees, to move their hands and feet, till at last they get up, and fall to dancing, with wonderful vigour at first, for three or four hours; then they

they are put to bed, refreshed from their sweating a short time, and repeat their exercise with the same vehemence, perceiving no weariness or weakness from it, but professing that they grow stronger and nimbler the more they dance. At this sport they usually spend twelve hours a day; and it continues three or four days, by which time they are freed from all their symptoms; which, nevertheless, attack them about the same time next year; and if they do not take care to prevent this relapse by music, they fall into the jaundice, want of appetite, universal weaknesses, and such like diseases, which are every year increased, if dancing be neglected, till at last they prove incurable. As music is the common cure, so they who are bitten are pleased, some with one sort of it, and some with another; one is pleased with a pipe, another with a timbrel, one with a harp, and another with a fiddle; so that the musicians sometimes make several essays before they can accommodate their art to the venom; but this is constant and certain, notwithstanding this variety, that they all require the quickest and briskest tunes; and are never moved by a slow dull harmony. While the Tarantati are dancing, they lose in a manner the use of all their senses, are like so many drunkards, do many ridiculous and foolish tricks, talk and act obscenely and rudely, take great pleasure in playing with vine-leaves, with naked swords, red cloaths, and the like; and, on the other hand, cannot bear the sight of any thing black; so that if any bystander happen to appear in that colour, he must immediately withdraw, otherwise they relapse into their symptoms with as much violence as ever. Baglivi, who resided in Italy, and probably had good opportunities of informing himself with respect to this insect, has written a treatise expressly upon the subject: and most medicinal writers mention the distempers arising from the bite thereof, as a thing certain.

But, notwithstanding all these great authorities, there is good reason to believe the whole story fabulous, and a vulgar error; for it is treated as such by an Italian physician, in the *Philos. Transf.* and a great many gentlemen of unquestionable veracity, who resided at Taranto many months, and during the time in which the bite of a tarantula is said to be most pernicious, affirm, that there was not a physician in the country, who believed there ever was such a distemper, from such a cause: that among the vulgar there is a tradition, that distempers attended with very extraordinary circumstances, had been excited by the bite of a tarantula; but that no body ever remembers a single instance; and that there is no other spider to be found in that country, different from those which are common in most warm countries.

TARANTOLA-FISH, a species of osmerus, with eleven rays in the pinna ani.

This fish is of the size of the smelt, or larger; the body is rounded, and the belly flat; its thickness is about that of a man's thumb, when its length is seven inches; the belly is white, the head is flattened, and there is a little furrow between the eyes; the opening of the mouth is very large, and the rostrum acute; there is in each jaw a single series of long teeth on each side of the palate; the back fin has twelve rays, and there is towards the extremity of the back a membranous appendage of the appearance of a fin, but without any rays; the pectoral fins have each thirteen rays.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that inclose, or bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed net. Several sorts of goods have their tares ascertained, and those are not to be altered or deviated from, in any case, within the port of London; unless the merchant thinking himself, or the officers of the crown, to be prejudiced by such tares, shall desire that the goods may be unpacked, and the net-weight taken; which may be done either by weighing the goods in each respective cask, &c. net; or, as is practised in East-India goods particularly, by picking out several casks, &c. of each size, and making an average, compute the rest accordingly. But this must not be done without the consent of two surveyors, attested by their hands in the

landwaiter's books; and in the out ports, not without the consent of the collector and surveyor. And as to those goods which have not their tares ascertained, two surveyors in London, and the collector and surveyor in the out-ports, are to adjust and allow the same, in like manner. Sometimes the casks, &c. are weighed beyond sea, before the goods are put in; and the weight of each respective cask, &c. marked thereon, as is usual for most goods imported from the British plantations, or else inserted in the merchant's invoice; in which case, if the real invoice be produced, and the officers have satisfied themselves, by unpacking and weighing some of them, that those weights are just and true, they do then, after having reduced them to British weight, esteem them to be the real tares, and pass them accordingly. But the unpacking goods, and taking the net-weight, being supposed the justest method, both for the crown and merchant, it is usually practised in the port of London, in all cases where it can be done with convenience, and without detriment to the goods.

TARGET, a kind of shield or weapon of defence made use of by the ancients.

TARGUM, a name whereby the Jews call the Chaldee paraphrases, or expositions, of the Old Testament, in the Chaldee language. After the captivity, the Jewish doctors, in order to make the people understand the Holy Scripture, which was read in Hebrew in their synagogues, were obliged to explain the law to them in a language they understood, which was the Chaldean, or that used in Assyria. The Targums now remaining, were composed by different persons, upon different parts of scripture, and are eight in number.

TARIF, or **TARIFF**, a table or catalogue, containing the names of different sorts of merchandize, with the duties to be paid, as settled by authority, amongst trading nations.

TARPAULIN, a piece of canvas, well tarred over, to keep out the rain from any place. The term is also used in derision to a person bred at sea, and educated in the mariner's art.

TARRACE, or **TERRACE**, a kind of plaster or mortar. See **TERRACE**.

TARSO, in the glass-trade, a white kind of stone, used instead of sand, for the finest crystal. See the article **GLASS**.

TARSUS, in anatomy, is the space between the bones of the leg and the metatarsus, consisting of seven bones, viz. the astragalus, or talus, calcaneum, navicular, three ossa cuneiformia, and the cubiforme.

TARSUS is also a name given, by some anatomists, to the cartilages which terminate the palpebræ, or eyelids, and from which the cilia or hairs arise.

They are exceedingly thin and fine, which makes them light and flexible.—Their form is semi-circular; that of the upper eye-lid is somewhat longer than that of the under: they serve alike to close the eyes.

TARTANE, a kind of bark used for fishing and carriage: they are flush fore and aft, and commonly use oars. They are plenty in the Mediterranean: they have only a main-mast and a mizen: their sails are triangular. When they put up a square sail, it is called a sail of fortune.

TARTAR, *Tartarum*, an acid concrete salt, thrown off from wines, after complete fermentation, to the sides and bottoms of the casks; of a red or white colour, and more or less drossy, according to the colour and quality of the wine. The white is generally purer than the red: both kinds, when purified, are exactly the same.

This salt is one of those which are most difficultly dissoluble in water, being scarcely affected by it in the cold, and requiring ten or twelve times its own weight when assisted by a boiling heat. From this saturated solution the tartar begins to separate almost as soon as the boiling ceases: if the quantity of water is greater, as about twenty times the weight of the salt, it continues long enough suspended to be passed, with due care, through a woollen strainer or a filter. The filtered liquor appears limpid and colourless, whether the tartar made use of was red or white: if hastily cooled, the salt separates in small grains like sand, but if the vessel is closely covered,

and the heat very leisurely diminished, it shoots into semitransparent white crystals: if the filtered liquor be kept boiling, a thick skin forms on the surface, which, being taken off with a perforated wooden skimmer, is succeeded by fresh cuticles, till the whole of the salt is thus formed into what is called *creme of tartar*. The refining of tartar is practised, in the way of trade, chiefly about Montpellier, from whence the shops are generally supplied both with the crystals and *creme*; the process being so troublesome, and requiring so large conveniences, that it is scarcely ever attempted here. The purer sort of white tartar, unrefined, especially that of Rhenish wine, is, for many purposes, particularly for combinations with other bodies, not inferior either to the *creme* or crystals.

Pure tartar, in doses of half a dram, or a dram, is a mild cooling aperient: two or three drams gently loosen the belly; and six or eight prove moderately cathartic. Its acidity and laxative power are its medical characters.

Tartar, dissolved in water, effervesces with fixed alkaline salts, and saturates, of the vegetable alkalies, near one third its own weight. The compound salt, resulting from their union, is a neutral one, more purgative than the tartar itself, and far easier of solution, whence its name soluble tartar. This salt is prepared, either by boiling the refined tartar in ten times its weight of water till it is dissolved, and then dropping in strong alkaline ley; or by dissolving the alkali in boiling water in the proportion of a pound to a gallon, and then adding the tartar, till a fresh addition occasions no further effervescence: the liquor is then filtered while hot, and either crystallized, or evaporated to dryness. As this salt difficultly crystallizes, inspissation to dryness is the most convenient method; and in this case, to secure the perfect neutralization of the salt, the tartar should be made to prevail at first, and the liquor suffered to cool a little before filtration, that the redundant tartar may concrete and separate from it.

Of the mineral fixed alkali or soda, this acid saturates, according to the faculty of Paris, four fifths its own weight. The neutral salt resulting from its coalition with this alkali, is somewhat less dissoluble than that with the vegetable; and shoots much more easily, into pretty large hard, multangular crystals, some columnar and flattish, others more irregular. It is milder in taste, and in virtue less purgative, requiring to be given to the quantity of an ounce or an ounce and a half to purge effectually: eight drams seem to be about equivalent, in cathartic power, to six of the soluble tartar.

Tartar forms likewise soluble compounds with all the absorbent earths, and with some metallic bodies; but with these last it is difficultly made to satiate itself completely, the part that is first saturated seeming to impede the action of the rest; for after long boiling, a very considerable part of the tartar separates on crystallization unchanged.

It is observable, that if any of these combinations of tartar, with alkalies, with earths, or with metals, be dissolved in water, and any other acid added, the pure tartar separates and falls to the bottom, as acid, and as difficult of solution, as at first; the substance, that was combined with it, being absorbed by the acid superadded. As the acids of the vegetable kingdom, whether native or fermented, vinegar, lemon juice, tamarinds, &c. have this effect of disuniting tartar from all the bodies that are combinable with it, equally with those of the mineral kingdom; it follows, that the tartareous acid is of a kind essentially different from all the other known vegetable ones, and that no acid, unless it be tartar itself, can be joined in prescription to the *tartarum solubile*, the *sel de Seignette*, or the combinations of tartar with earths or metals.

TARTARY, a vast country in the northern parts of Asia, bounded by Siberia on the north and west: this is called Great Tartary. The Tartars who lie south of Moscow and Siberia, are those of Astracan, Circassia, and Dagestan, situated north-west of the Caspian sea: the Calmuc Tartars, who lie between Siberia and the Caspian sea: the Usbec Tartars and Moguls, who lie

north of Persia and India: and, lastly, those of Tibet, who lie north-west of China.

TASSEL, a sort of pendent ornament at the corners of a cushion or the like.

In building, tassels denote those pieces of board that lie under the ends of the mantle-trees.

TASTE, *Savour*, in physiology, a peculiar sensation, excited by means of the organs of taste, viz. the papillæ on the tongue.

The tastes of bodies depend on a certain determinate magnitude of their particles, adapted to excite different sensations by means of the papillæ of the tongue.

Savours, which are the objects of the taste in general, proceed chiefly from the saline parts, which are found in all matters, whether animal or vegetable, which we take either as food or physic. These little angular pungent bodies are fitter than others to penetrate even to the immediate organ, and to make themselves perceived there: we may judge of them by putting a grain of pure salt, of any kind whatever, upon the tongue, where it will make a very strong impression; and their analysis discovers, that, of all mixed bodies, those that affect the organ most, are such as abound most in salts. See SALT.

The most simple favours, and upon which men are more generally agreed, are those wherein the salts are the least mitigated by the mixture of other matters. Every one knows what is meant by salt, sour, sweet, bitter, harsh, &c. These different sensations are so remarkable that they are presently distinguished: they are, as it were, the basis of all others, which become so much the more difficult to describe and express, the more they recede from their primary simplicity. The bitterness of coffee, for example, corrected by the sweetness of sugar, produces a mixed sensation; the juice of fruits, mingled with spirit of wine, takes a new taste: the taste of victuals changes almost entirely, and is disguised a thousand different ways, by that infinite number of preparations and mixtures, which the present age has rendered an important art.

TASTE is also used, in a figurative sense, for the judgment and discernment of the mind.

We constantly hear talk of good and bad taste, without well understanding the meaning of these terms: in effect, a good taste seems, at bottom, to be little else but right reason, which we otherwise express by the word judgment. Mad. Scudery and Mad. Dacier call good taste a harmony between the mind and reason; and according as that harmony is more or less just, the person has more or less of this taste.

TATIANITES, in church history, Christian heretics in the second century; so called from their leader Tatian, a disciple of St. Justin.

This heresiarch took from Valentinus the fable of the æons, and from Marcion the doctrine of two principles. But what particularly distinguished his followers was, their condemning of marriage, and forbidding the eating of flesh or drinking of wine.

TAT-TOO, q. d. a beat of a drum at night, to advertise the soldiers to retreat or repair to their quarters in their garrison, or to their tents in a camp.

TAURUS, the bull, in zoology. See the article BULL.

TAURUS, in astronomy, one of the twelve signs of the zodiac, the second in order, consisting of 44 stars, according to Ptolemy; of 41, according to Tycho; and of no less than 135, according to the Britannic catalogue.

TAUTOLOGY, in rhetoric, a needless repetition of the same thing in different words.

TAWING, the art of dressing skins in white, so as to be fit for divers manufactures, particularly gloves, &c.

All skins may be tawed; but those chiefly used for this purpose are lambs, sheep, kids, and goat-skins.

The method of tawing is this: Having cleared the skins of wool or hair, by means of lime, &c. as described under the article SHAMMY, they are laid in a large vat of wood or stone set on the ground full of water, in which quick-lime has been slaked, wherein they are allowed to lie a month or six weeks, according

ing as the weather is more or less hot, or as the skins are required to be more or less soft and pliant.

While they are in the vat, the water and lime is changed twice, and the skins are taken out and put in again every day; and when they are taken out for the last time, they are laid all night to soak in a running water, to get out the greatest part of the lime; and in the morning are laid together by sixes one upon another, upon the wooden leg, and are scraped stoutly one after another, to get the flesh off from the fleshy side, with a cutting two handled instrument called a knife; and then they cut off the legs, if they are not cut off before, and other superfluous parts about the extremes. Then they are laid in a vat or pit with a little water, where they are felled with wooden pestles for the space of a quarter of an hour, and then the vat is filled up with water, and they are rinsed in it.

In the next place, they are thrown on a clean pavement to drain, and afterwards cast into a fresh pit of water, out of which they rinse them well, and are laid again on the wooden leg, six at a time, with the hair-side outmost, over which they rub a kind of whetstone very briskly to soften and fit them to receive four or five more preparations, given them on the leg, both on the flesh side and the hair-side, with the knife, after the manner above-mentioned.

After this they are put into a pit of water and wheaten-bran, and stirred about in it with wooden poles, till the bran is perceived to stick to them, and then they are left; as they rise of themselves to the top of the water by a kind of fermentation, they are plunged down again to the bottom, and at the same time fire is set to the liquor, which takes as easily as if it were brandy, but goes out the moment the skins are all covered.

They repeat this operation as often as the skins rise above the water; and when they have done rising they take them out, lay them on the wooden leg, the fleshy side outwards, and pass the knife over them to scrape off the bran.

Having thus cleared them of the bran, they lay the skins in a large basket, and load them with huge stones to promote their draining: and when they have drained sufficiently, they give them their feeding, which is performed after the manner following:

For one hundred of large sheep skins, and for smaller in proportion, they take eight pounds of alum, and three of sea-salt, and melt the whole with water in a vessel over the fire, pouring the dissolution out, while yet luke-warm, into a kind of trough, in which is twenty pounds of the finest wheat-flour, with the yolks of eight dozen of eggs; of all which is formed a kind of paste, a little thicker than children's pap; which, when done, is put into another vessel, to be used in the following manner:

They pour a quantity of hot water into the trough in which the paste was prepared, mixing two spoonfuls of the paste with it; to do which they use a wooden spoon, which contains just as much as is required for a dozen of skins; and, when the whole is well diluted, two dozen of the skins are plunged into it; but they take care that the water be not too hot, which would spoil the paste and burn the skins.

After they have lain some time in the trough, they take them out, one after another, with the hand, and stretch them out; this they do twice; and after they have given them all their paste, they put them into tubs, and there fill them afresh with wooden pestles.

Then they put them into a vat, where they are suffered to lie for five or six days, or more; then they take them out in fair weather, and hang them out to dry on cords or racks, and the quicker they are dried the better; for if they be too long a-drying, the salt and alum within them are apt to make them rise in a grain, which is an essential fault in this kind of dressing.

When the skins are dry, they are made up into bundles, and just dipped in fair water, and taken out and drained; and being thrown into an empty tub, and after having lain some time, are taken out and trampled under foot.

Then they draw them over a flat iron instrument, the top of which is round like a battledore, and the bottom fixed into a wooden block, to stretch and open them; and having been opened, they are hung in the air upon cords to dry: and being dry, they are opened a second time, by passing them again over the same instrument. In the last place they are laid on a table, pulled out, and laid smooth, and are then fit for sale.

After the same manner are dressed horses, cows, calves, skins, &c. for the saddlers, harness makers, &c. as also those of dogs, wolves, bears, &c. except that in these they omit using the paste, salt and alum-water being sufficient.

TAX, a tribute rated upon every town, which formerly was wont to be paid annually into the King's-Exchequer, but now not without consent of parliament; it differs from a subsidy in this, that it is always certain, as set down in the Exchequer-book, and in general levied of every town, and not particularly of every man, &c. The antient way of levying taxes was by tenths and fifteenths, afterwards by subsidies and royal aids, and at length by a pound rate; the former of these were all upon the person and personal estate, but the last upon lands and rents. In the late reigns, a land-tax has been annually granted of two, three, or four shillings in the pound, according to present exigencies, to be levied by commissioners on the several counties, cities, towns, &c. And in respect of this tax, the tenants, or occupiers, of the land are to be charged or assessed, and the same deducted out of the rent due to the landlords; and if any persons refuse to pay what they are rated, the collectors in every parish may levy it by distress and sale of their goods; but in case they are over-rated, they may be relieved by an appeal to the commissioners, who have power to charge the overplus on others, as they shall see cause; or where there appears to be a deficiency, they may make a re-assessment, &c.

TAXIS, a term used by Vitruvius for what is now called ordonnance, being that which gives every part of a building its just dimensions with respect to its uses. See **ORDONNANCE**.

TAXUS, the yew-tree, in botany, a genus of plants, without any corolla. The calyx of the male flower is composed of three leaves: the stamina are numerous: the seed is single, and surrounded by an undivided baccated calyx: the tree is very slow in growing, but there are many very large ones upon some barren cold soils in divers parts of England; the timber is much esteemed for many uses.

There is hardly any sort of ever-green tree, which has been so generally cultivated in the English gardens as the yew, upon the account of its being so sensible, as to be with ease reduced into any shape the owner pleased; and it may be too often seen, especially in old gardens, what a wretched taste of gardening prevailed formerly in England, from the monstrous figures of beasts, &c. we find these trees reduced into; but of late this taste has been justly exploded by persons of superior judgment; for what could be more absurd than the former methods of planting gardens? where, those parts next the habitation were crowded by a large quantity of these and other sorts of ever-green trees, all of which were clipped into some trite figure or other, which besides the obstructing the prospect from the house, filled up the ground; so that little room was left for other shrubs and flowers. Besides, it occasioned an annual expence to render the trees disagreeable; for there never was a person who had considered the beauty of a tree in its natural growth, with all its branches diffused on every side, but must acknowledge such a tree infinitely more beautiful than any of those shorn figures so much studied by persons of a grovelling imagination.

The only use this tree is fit for in gardens, is to form hedges for the defence of exotic plants; for which purpose, when it is necessary to have hedges, it is the most proper of any tree in being; the leaves being small, the branches are produced very closely together; and if carefully shorn, they may be rendered so close, as to break the winds better than any other sort of fence whatever, because they will not be reverberated, as against walls, pales,

pales, and other close fences; therefore consequently, are much to be preferred for such purposes.

These trees may be easily propagated by sowing their berries in autumn, as soon as they are ripe, upon a bed of fresh undunged soil, covering them over about half an inch thick with the same earth.

In the spring the bed must be carefully cleared from weeds, and if the season prove dry, it will be proper to refresh the bed with water now and then, which will promote the growth of the seeds; many of which will come up the same spring, but others will remain in the ground until autumn or spring following; but where the seeds are preserved above ground till spring before they are sown, the plants never come up till the year after, so that by sowing the seeds as soon as they are ripe, there is often a whole year saved.

These plants, when they come up, should be constantly cleared from weeds, which, if permitted to grow amongst them, would cause their bottoms to be naked, and frequently destroy the plants when they continue long undisturbed.

In this bed the plants may remain two years; after which, in autumn, there should be a spot of fresh undunged soil prepared, into which they should be removed the beginning of October, planting them in beds about four or five feet wide, in rows about a foot asunder, and six inches distance from each other in the rows, observing to lay a little mulch upon the surface of the ground about their roots, as also to water them in dry weather until they have taken root; after which they will require no farther care, but to keep them clear from weeds in summer, and to train them according to the purpose for which they are designed.

In these beds they may remain two or three years, according as they have grown, when they should again be removed into a nursery, placing them in rows at three feet distance, and the plants eighteen inches asunder in the rows, observing to do it in autumn, as before directed, and continue to trim them in the summer, for what they are intended; after they have continued three or four years in this nursery, they may be transplanted where they are to remain, always observing to remove them in autumn where the ground is very dry; but on cold moist land it is better in the spring.

These trees are very slow in growing, but yet there are many very large trees upon some barren cold soils, in divers parts of England. The timber of these trees is greatly esteemed for many uses.

TEA, the leaf of an oriental shrub, called by Caspar Bauhine, *Chaa herba* in Japonia; by Breynius and Ray, the *Sinenfium five t'sja Japonensibus*; by Kämpfer *Thea frutex*, &c. "The tea shrub, with leaves like those of the cherry-tree, flowers like those of the dog-rose, and a fruit composed of one, two, and, for the most part, three berries." This plant comes the nearest, in its general appearance, to the dog-rose, but is smaller, and without prickles. Dr. Cleyer, who lived some time in the East-Indies, sent several specimens to Simon Pauli in Denmark, and Dr. Mentzel in Berlin; of which figures may be seen in the *Acta Hafnienfis*, and the *German Ephemerides*.

Only one species of the tea-plant is as yet known; the differences in this commodity, as brought to us, proceeding from a difference in the climate, soil, age, method of collection and curation: some indeed mention a single and a double-flowered sort, but of this we have no certainty.

It is said by some to be a native of China only, by others both of China and Japan: others add a third country, namely, Siam; and suppose, not without probability, that the Japonic name *Tsia* is derived from thence. Thus much is certain, that at present it is regularly cultivated in different provinces of Japan and China, but does not in all prove of equal goodness: Fisien in Japan, and Nankin in China, produce the best.

The Chinese plant whole fields with tea; the Japanese only the borders of fields fronting the south. From six to a dozen of the berries are planted together, as they are very apt to fail; and covered with dung and earth: it is said, that they are three years in coming up,

and that they are carefully covered in the winter with straw. After a certain number of years, which Kämpfer limits between seven and ten, appear the admired leaves: after these have been gathered, the plant is either cut down, and new shoots expected from the root, or extirpated and renewed from seed. As the berries are extremely apt to spoil, inasmuch as to require being planted quite fresh in their native climate, and as the shrub does not bear being removed entire, there are little hopes of our being ever able to introduce it into Europe; nor would it, probably, in these colder climates, prove equal in quality to the Chinese, since even in China and Japan it proves greatly different in different provinces.

If the winter does not prove very severe, the leaves come forth in February, and about the end of this month, or the beginning of next, the first collection is made. These early tender leaves are the true Imperial, called also improperly bloom tea; but they cannot be the sort to which the Dutch give that name, as being sold upon the spot, to the princes of the country, for vastly more than the common bloom-tea is sold for in Europe. About the end of March or the beginning of April, the second and most considerable crop is gathered: a large linen cloth is stretched over the bush, to defend from the sun not only the gatherers, but the leaves themselves, lest they should dry too fast, and lose their flavour. The leaves are picked one by one, so curiously, that the most industrious can scarcely collect four pounds in a day. They are commonly divided into four sortments; of which the smaller upper ones are the best, the larger lower ones the worst, and the intermediate of a middling goodness. The third collection is in the end of April or beginning of May; this likewise affords different sorts, which are those mostly brought into Europe: the very best sort which we meet with here, called imperial tea, is but the lower leaves of the second crop. About the end of May, all the leaves on the plant are gathered promiscuously, without sorting, and sold about the streets to the poorer people; these being the worst of all, and unfit for being cured in the Chinese manner.

The Japanese, who swallow their tea in substance along with its infusion, dry it hastily in iron pans over the fire, and grind it into powder. The Chinese, on the other hand, are very curious of preserving the leaves entire; and roll them up that they may be less apt to break in carriage. So soon as gathered, they are brought into an apartment furnished with a number of little furnaces, each of which is covered with a smooth iron plate. The leaves are spread upon the plates, and kept rolling with the hands, in one direction, till they become moderately dry, and begin to curl up about the edges, when they are immediately swept off upon tables covered with smooth close mats, on which one person continues to roll them over and over, whilst another fans them, that they may cool hastily, and retain the curl. This process is repeated two or three times or oftener, according as the leaves are disposed to unbend upon standing. If exsiccated without artificial heat, or by a very soft one, they rarely take the curl, and never hold it.

Meister relates, that the leaves are put into a hot kettle just emptied of boiling water; and that in this they are kept closely covered till cold, and then committed to the hot plates: according to Lemery, they are held in the steam of water. But Kämpfer mentions nothing of all this; and if any such thing is practised in regard to green-tea, it is to be supposed it is only for softening such of the leaves as have happened to grow too dry, and would break in the curling. Boerhaave pretends that the preparers employ green vitriol for improving the colour of the tea: this must certainly be false, because green vitriol, instead of heightening the green colour of tea, changes it to an inky blackness.

Thus much of the green-tea. With regard to bohea, we have not been able to meet with any satisfactory account, either in books, or from the communication of merchants, of both which great numbers have been consulted. Kämpfer, and Dr. Cunningham, physician to the English settlement at Chusan, affirm, that it is the leaves of the first collection; but this must certainly be a mistake, as all the travellers agree that none of the first crop

crop is brought into Europe, but that it is all reserved for the princes of the land, and sold at an immense price in China itself; whereas bohea comes over in large quantity, and is cheaper than the second and third crops, if not than the fourth also. Possibly a particular kind of bohea is made from the first crop, for the use of the nobility; and our bohea, prepared in imitation of that, from the third and fourth collections, or perhaps from the earlier growths also in those provinces where the plant does not come to such perfection as to afford a good green-tea. The dark-brownish colour, and rose flavour observed in this kind of tea, I hold, with Sigesbeck, to be artificial: the method of curation described by Meister, which certainly is in general not practised for the green, probably is for the bohea, which receives, perhaps, in the kettle, both its tincture and its flavour. This at least is certain, that by a similar process good bohea may be made among ourselves; a specimen of which I have exhibited to a numerous audience. Some of the dealers in this commodity, in England, are not ignorant that certain European leaves, particularly those of the dog-rose and cherry tree, may be so coloured and prepared, as to pass for good bohea. But I forbear to say any thing further of this manufacture, lest a handle should be given for new abuses.

The Japan tea has been observed to be of a clearer green colour than the Chinese, and to have its leaves smaller; but which of the two is the best has not hitherto been determined, some preferring the one, and others the other: this controversy does but little concern us, the Chinese being the only one brought into Europe. In China, tea is divided into a great number of different fortments: there are sixteen or twenty of the green leaves, from the difference in the collection only; and these are further multiplied, when the leaves are dry, by picking out such as have miscarried in the preparation. Among us, there are three principal kinds of green, and five of bohea: from what province they are brought, of what crop they are the produce, and to which of the Chinese sorts they belong, is unknown: they have all names, but these are merely arbitrary, and serve only for the conveniency of the dealer. The best of the green-teas is called *bing*, imperial and bloom-tea, *Thea imperialis folio amplo laxo* of Dale: the second best *Hysson*, *Thea viridis optima folio oblongo* Dal: the third or worst, *Singlo*, *Thea viridis folio minore* Dal. Of bohea (*Thea fusca folio ad nigredinem vergente*) the sorts are ordinary, *pecco*, *congo*, *camho*, and *fouchong*; of which the first is the worst, and the last the best.

The Chinese are extremely curious and cleanly in every branch of the tea manufacture. They gather the leaves, as I have been well assured, with gloves made of a thin kind of leather. The workmen employed in the curation are restrained, for a fortnight before, from flatulent foods, and whatever might endanger communicating any ill flavour. The tea, when cured, is packed up in large vessels made of a mixture of lead and tin called *calin*, or in wooden chests lined with this composition, or in cannisters of tinned plates soldered with the same, so tight, that they may be kept occasionally under water.

As soon as tea became known in Europe, with its uses among the Chinese, all the European nations thirsted after it. Its great price at that time confined it to the rich, whence the learned were induced to examine the European plants, with a view to discover a cheap succedaneum to it. The most celebrated of our substitutes is *veronica*, on which Hoffmann and Joh. Francus have written particular dissertations. The leaves of the red whortle-berry and rose-bush are at present in greater esteem, and come nearer to the taste of the true tea than any of the other plants that have been employed for this purpose, as *betony*, *nettles*, *agrimony*, *coltsfoot*, *eyebright*, *strawberry*, *scabious*, *cow-slips*, *golden-rod*, *cherry-tree*, *peach-tree*, *wall-rue*, *sharp-leaved plantane*, *sanicle*, *liverwort*, *lungwort*, *brankursine*, *balm*, *sage*, *rosemary*, &c. It must be acknowledged that these plants are possessed of considerable virtues; greater in particular cases, than any that tea can pretend to; yet still they want the chief excellence of tea, that of being a diluent almost universally acceptable.

Some pretended to have discovered the oriental tea itself in Europe or America. The first of these was Simon Paulli, who obstinately maintained that tea was no other than the *chamæleagnus* or Dutch myrtle, but was refuted by several botanists in Europe, and by the specimens sent by Dr. Cleyer. The next was father Labat, who in his *Voyages to America* relates, that in Martinico there grows a plant called wild tea, agreeing in all respects with the China, fort except that it has not so much of the violet smell; for in every other respect, he says, it is assuredly the same thing. He adds further, that he had procured tea-seeds from the East Indies, and raised the plant in America. That he was mistaken here, as he often was in botanic matters, is obvious from his own account: his seeds were smaller than poppy seeds, whilst those of tea are a kind of large nut or berry: his flowers had each but four stamina, whilst in one of the tea-flowers Kämpfer counted two hundred and thirty. The plant is no other than that called in England West-India tea, found in great plenty by Sir Hans Sloane about Spanish-town in Jamaica. About twenty years ago there was another pretended discovery of tea in the Imperial dominions; but this like the others, when examined by a botanist, was found to be a quite different plant; and the Jesuits have at times made great noise with this plant, under the name of Roman tea.

The oriental tea, as we have already seen, is of two kinds, green and bohea. The first is not only externally green, but likewise imparts the same colour to water; the fresher the tea, the greener is the infusion; its prevailing smell is generally that of violets or new hay: bohea on the other hand is externally of a blackish brown colour, gives a brownish tincture to water, and smells of roses. Green tea should be chosen fresh, of a fine colour, not inclining to a yellowish or brownish, which are marks of too great age, well rolled, consisting of entire leaves, thoroughly dry, so as to be friable betwixt the fingers, of a bitterish subastringent not ungrateful taste, and a pleasant light smell. When either the violet or hay-smell are very strong, we may suspect them to be introduced by art, the leaves having but little from nature: the first is communicated by putting into the cannisters a little Florence orris root; the latter, by placing the tea for a few days, wrapt in papers, among new made hay; this leaf being remarkably susceptible of any kind of flavour. There are other abuses common among the Dutch: as mixing, with the tea, leaves of European growth and manufacture; and introducing into the old decayed green, a fresh tincture.

The preparation and use of tea as a dietetic liquor, are in general well known. With regard to its medical effects, some have excessively extolled, and others as extravagantly condemned it. Tea is in many cases a very useful liquor; a grateful diluent in health, and a salutary drink in sickness: it attenuates viscid juices, promotes the natural excretions, excites appetite, and proves serviceable particularly in fevers, in immoderate sleepiness, after a debauch, and in head-achs arising from that cause; no other plant is known, whose infusion passes off more freely by the emunctories of the body, or more speedily excites the spirits. It is not however without its inconveniencies: in habitual colics it is found to do harm, and in urinary obstructions it should be sparingly drank: its immoderate use is productive of cacochymic, cachectic, chlorotic disorders, and weakens the tone of the stomach and nervous system. It is said, when new, to be narcotic, and to disorder the senses; but to lose this quality, in great part by the exsiccation, and totally by being kept for a year: in the tea countries, it is a principal caution to abstain from it till this period, but in Europe there is no danger of its being used too new.

Some ascribe the good or ill effects observed from the use of tea wholly to the leaves, and others to the water. The simple element has undoubtedly a considerable share in both: it is not, as some have supposed, the virtue of the tea-leaf, but the warm aqueous liquor, with the climate and diet, that preserves the inhabitants of China and Japan from calculous and gouty disorders. But on the other hand, that the herb communicates also some peculiar qualities to the liquor is equally certain: in

weak stomachs, a moderately strong infusion of tea, without sugar, generally provokes a puke: an infusion of two or three drams of bohea in two ounces of water, is a common emetic among the Chinese; and the green is sometimes employed in the like intention among ourselves.

Both the green and bohea teas have an agreeable smell, a lightly bitterish subastringent taste, as hath been already observed: with solution of chalybeate vitriol, they strike an inky blackness. They give out their smell and taste both to watery and to spirituous menstrua: to water, the green sorts communicate their own green tincture, and the bohea their brown: to rectified spirit they both impart a fine deep green. On gently drawing off the menstrua from the filtered tinctures, the water is found to elevate nearly all the peculiar flavour of the tea, while rectified spirit brings over little or nothing, leaving the smell as well as the taste concentrated in the extract: both extracts are very considerably astringent, and not a little ungrateful: the spirituous most so.

TEARS, *Lachrymæ*, a watery humour issuing out at the corner of the eye by the compression of the muscles, serving to moisten the cornea, to express our grief, and even to alleviate it.

TEASEL, or TEAZEL, *carduus fullonum*, in botany. See the article DIPSACUS.

This plant is much used by the fullers, cloth-workers, and stocking-weavers, to card or draw out the wool or nap from the thread or ground of several kinds of cloth, stuffs, stockings, &c. in order to render them closer and warmer.

This plant is propagated by sowing the seeds in March, upon a soil that has been well prepared. About one peck of seed will sow an acre; for the plants should have room to grow, otherwise the heads will not be so large, nor in so great quantity. When the plants are come up, they must be hoed in the same manner as is practised for turnips, cutting down all the weeds, and singling out the plants to about eight inches distance; and as the plants advance, and the weeds begin to grow again, they must be hoed a second time, cutting out the plants to a wider distance; for they should be, at last, left at least a foot asunder: and should be kept clear from weeds, especially the first summer; for when the plants have spread so as to cover the ground, the weeds will not so readily grow between them. The second year after sowing, the plants will shoot up heads, which will be fit to cut about the beginning of August; at which time they should be cut, and tied up in bunches, setting them in the sun, if the weather be fair; but if not, they must be set in rooms to dry them. The common produce is about an hundred and sixty bundles or staves upon an acre, which they sell for one shilling a staff. Some people sow caraway and other seeds amongst their teasels; but this is not a good method, for the one spoils the other; nor can the weeds be so well cleaned away from the teasels.

TEBETH, the tenth month of the Jewish ecclesiastical year, and fourth of the civil. It answers to our month of December.

TECHNICAL expresses somewhat relating to arts or sciences: in this sense we say technical terms. It is also particularly applied to a kind of verses wherein are contained the rules or precepts of any art, thus digested to help the memory to retain them; an example of which may be seen in the article MEMORY.

TE DEUM, the name of a celebrated hymn, used in the Christian church, and so called because it begins with these words, *Te Deum Laudamus*; We praise thee, O God. It is sung in the Romish church, with great pomp and solemnity, upon the gaining of a victory, or other happy event.

TEETH, *Dentes*. See the article TOOTH.

TEGUMENT, or INTEGUMENT, any thing that surrounds or covers another. The common teguments of the human body are the cutis, cuticle, and fat.

TEINTS, and SEMI-TEINTS, in painting, denotes the several colours used in a picture, considered as more or less high, bright, deep, thin or weakened, and diminished, &c. to give the proper relievo, softness, or distance, &c. of the several objects.

TELAMON, or ALAS, a name given to those figures or half figures of men so commonly used instead of columns or pilasters, to support any member in architecture, as a balcony, or the like.

TELESCOPE, an optical instrument consisting of several lenses, by means of which remote objects are so magnified as to appear nigh at hand.

That the telescope is of a modern invention is most certain; neither does it appear that microscopes, or optic glasses of any kind, were known to the ancients.

It is contended, that Alexander de Spina, a native of Pisa, was the first that made the use of glasses known to the world; but our countryman, friar Bacon, who died twenty-one years before him, was, in all probability, acquainted with them first; for he wrote a book of perspective, in which he plainly shews that he did not only understand the nature of convex and concave glasses, but the use of them when combined in telescopes; though he no where, in that treatise, discovers the manner in which they are to be put together. The telescope, with the concave eye glass, was first invented by a mechanic of Middleburgh in Zealand, called Z. Johannides, about the year 1590, though J Lipperhoy, another Dutchman, is candidate for the same discovery; from whence this sort of telescope is called *tubus Batavus*.

Franciscus Fontana, a Neapolitan, contends, that he was the first contriver of the telescope composed of two convex glasses, which is now the common astronomical telescope; and Rheita pretends to be the first that rendered that telescope fit for terrestrial uses, by adding two eye-glasses to it.

The telescope is of two sorts, viz. dioptric, or refracting; or cata-dioptric, by reflection and refraction conjointly.

Dioptric or Refracting TELESCOPE consists of an object-glass xx (plate CXXVI. fig. 3.) by which the image fd of an object OB , at a distance, is formed in the focus e of the said glass, and in an inverted position. This image may be viewed by a single lens, ab , placed at its focal distance, as is usually done for viewing the heavenly bodies, because in them we do not regard the position: but for viewing objects near us, whose image we would have erect, we must, for that purpose, add a second lens pq , at double its focal distance from the other, that the rays which come from ab may cross each other in the focus o , in order to erect the image gn , which it will form in its own focus m , because the rays come parallel from the first lens ab . Lastly, a third lens ic is added, to view the secondary image gn . These three lenses, or eye-glasses, are usually of the same size and focal length; and the power of magnifying is always as the focal length of the object-glass ew divided by the focal length of the eye-glass lm or he : for instance, suppose $ew = 10$ feet or 120 inches, and he or $lm = 3$ inches; then will the object appear to the eye, through such a telescope, 40 times bigger than to the naked eye; and its surface will be magnified 1600 times, and its bulk or solidity 64000 times.

If instead of a convex eye-glass we should use a concave one of the same focal length, it would represent the object erect, equally magnified, and more distinct and bright; but the disadvantage of this glass is, that it admits but of a small area, or field of view, and, therefore, not to be used when we would see much of an object, or take in a great scope; but it is used to great advantage in viewing the planets and their satellites, Saturn's ring, Jupiter's belts, &c.

The manifesting power of a refracting telescope is thus estimated. Let AB (fig. 4.) be the object-glass, and CD the eye-glass; and let HFI and GFM be two rays coming from the extreme parts of a distant object, and crossing each other in the center F of the glass AB . Then is the angle $GFH = IFM$, that under which the object appears to the naked eye; but $IE M = CKD$ is that under which the image appears as magnified by the eye-glass CD . But the angle $IE M$ is to the angle IFM , as LF to LE , or as the focal distance of the object-glass to the focal distance of the eye-glass; and in that proportion is the object magnified.

There is a defect in all telescopes of this kind, not to be remedied by any means whatever, which was thought only

only to arise from hence, viz. that spherical glasses do not collect rays to one and the same point; but it was happily discovered by Sir Isaac Newton, that the imperfection of this sort of telescope, so far as it arises from the spherical form of the glasses, bears almost no proportion to that which is owing to the different refrangibility of light. This diversity in the refraction of the rays is about a twenty-eighth part of the whole, so that the object-glass of a telescope cannot collect the rays, which flow from any one point in the object, into a less room than the circular space, whose diameter is about the fifty-sixth part of the breadth of the glass. Therefore, since each point of the object will be represented in so large a space, and the centers of those spaces will be contiguous, because the points in the objects the rays flow from are so, it is evident that the image of an object made by such a glass must be a most confused representation, though it does not appear so when viewed through an eye-glass that magnifies in a moderate degree; consequently, the degree of magnifying in an eye-glass must not be too great with respect to that of the object-glass, lest the confusion become sensible. Notwithstanding however this imperfection, a dioptrical telescope may be made to magnify in any given degree, provided it be of sufficient length; for the greater the focal distance of the object-glass is, the less may be the proportion which the focal distance of the eye-glass may bear to that of the object-glass, without rendering the image obscure. Thus an object-glass, whose focal distance is about four feet, will admit of an eye-glass whose focal distance shall be little more than one inch, and, consequently, will magnify almost forty-eight times: but an object-glass of forty feet focus, will admit of an eye-glass of only four inch focus, and will therefore, magnify 120 times; and an object-glass of an hundred feet focus, will admit of an eye-glass of little more than six inch focus, and will therefore magnify almost 200 times.

The reason of this disproportion, in their several degrees of magnifying, is to be explained in the following manner: since the diameters of the spaces, into which rays flowing from the several points of an object are collected, are as the breadth of the object-glass, it is evident, that the degree of confusedness in the image is as the breadth of the glass, for the degree of confusedness will only be as the diameters or breadths of those spaces, and not as the spaces themselves. Now the focal length of the eye-glass, that is, its power of magnifying, must be as that degree; for, if it exceeds it, it will render the confusedness sensible; and, therefore, it must be as the breadth or diameter of the object-glass. The diameter of the object-glass, which is as the square root of its aperture or magnitude, must be as the square root of the power of magnifying in the telescope; for, unless the aperture itself be as the power of magnifying, the image will want light: the square root of the power of magnifying, will be as the square root of the focal distance of the object-glass; and, therefore, the focal distance of the eye-glass must be only as the square root of that of the object-glass. So that in making use of an object-glass of a longer focus, suppose than one that is given, you are not obliged to apply an eye-glass of a proportionably longer focus than what would suit the given object-glass, but such a one only whose focal distance shall be to the focal distance of that which will suit the given object glass, as the square root of the focal length of the object glass you make use of, is to the square root of the focal length of the given one. And this is the reason that longer telescopes are capable of magnifying, in a greater degree than shorter ones, without rendering the object confused or coloured.

Cata-dioptric, or Reflecting TELESCOPE, is the most noble and useful of all others; the mechanism of which is as follows:

A B E H, *fig. 5.* is the large tube, or body of the instrument, in which B E is a large reflecting mirror, with a hole in the middle C D. This mirror receives the rays, *a, c, b, d*, coming from the object at a distance, and reflects them converging to its focus *e*, where they cross each other, and form the inverted image I M; *x y* is a small concave mirror, whose focus is at *f*, at a small distance from the image. By this means the rays coming

from the image are reflected back through the central hole C D of the large mirror, where they fall on the plano-convex lens W X, and are by it converged to a focus, and there form a second image R S, very large and erect, which is viewed by a meniscus eye-glass Y Z, by the eye at P, through a very small hole in the end of the eye-piece Y C D Z. If the first lens W X were taken away, the image would be formed somewhat larger at M I; but the area or scope would be less, and therefore the view not so pleasant. At T V is placed a circular piece of brass, with a hole of a proper size to circumscribe the image, and cut off all superfluous or extraneous rays, that so the object may appear as distinct as possible.

As the image is formed by reflection, the rays of every sort will be united nearly in one point, and will therefore admit of an eye-glass Y Z of a deep charge, or small focal distance; and so the power of magnifying will be proportionally increased.

The magnifying power of a reflecting telescope is thus computed. The parallel rays K B (*fig. 6.*) and L E are reflected by the large object speculum A F to its focus *a*, where the image I M is formed; which image is defined by two other rays N Q, P Q, coming from the extreme parts of the object at a remote distance, and meeting in the center of the large speculum at Q. Now, if *f* be the focus of the small mirror G H, supposing the image were formed in the said focus *f*, that is, that both the foci *a* and *f* were coincident, then the rays proceeding from the image I M will proceed parallel after reflection, and produce distinct vision of the image, which will then subtend an angle I O M at the center O of the speculum G H, which is to the angle I Q M, under which the object appears to the naked eye, as *a Q* to *a O* or *f O*. So that the magnifying power would in this case be as $\frac{a Q}{f O}$.

But, to increase this magnifying power, the image I M is not placed in the focus of the small speculum; but at a small distance beyond it; by which means the rays coming from the image to the speculum G H will be reflected converging to a distant focus R, where a secondary large image I M is formed from the first image I M; which image I M is seen under the same angle I O M with the former from the center of the speculum G H: but from the center of the eye-glass T V it is seen under the large angle I S M. But the angle I S M is to the angle I O M as O R to S R; wherefore the second ratio, or part of the magnifying power, is that of $\frac{O R}{S R}$.

Consequently the whole magnifying power of the telescope is $\frac{a Q}{a O} \times \frac{O R}{S R}$, because in this case *f O* becomes *a O*. Or in other words, the angle N Q P, under which the object appears to the naked eye, is to the angle I S M, under which the large magnified secondary image I M appears to the eye through the eye-glass, as $\frac{a Q \times O R}{a O \times S R}$. Such is the theory of the telescope first

contrived by Dr. J. Gregory, and therefore called the Gregorian telescope; but it received its last improvement from the late Mr. Hadley, and is now in common use.

A small alteration was made in the structure of this telescope by Mr. Cassegrain, viz. in using a convex speculum G H (*fig. 7.*) instead of the concave one G H. Now if they are equally spherical, that is, if they are segments of the same sphere, then will *f* be also the virtual focus of the convex G H; and if all other things remain the same, the first image I M will be virtually the same as before, and the last image I M will be really the same: so that the magnifying power of this form of the telescope is $\frac{a Q \times O R}{a O \times S R}$ which is equal to that of Gregory's form.

Sir Isaac Newton ordered this telescope to be made in a different form or manner, as follows: A B C D (*fig. 8.*) was a large octagonal tube or case; E F a large polished speculum, whose focus is at *a*; G H a plane speculum truly concentrated, and fixed at half a right angle with the

the axis of the large one. Then parallel rays aE, bF , incident on the large speculum EF , instead of being reflected to the focus o , were intercepted by the small plane speculum GH , and by it reflected towards a hole cd in the side of the tube, crossing each other in the point O , which is now the true focal point; and from thence they proceed to an eye-glass ef placed in that hole, whose focal distance is very small, and therefore the power of magnifying may be very great in this form of the telescope; because the image IM is made by one reflection; for that of the plane speculum only alters the course of the rays, and adds nothing to the confusion of the image, and will, for that reason, bear being viewed by a glass of a very deep charge, in comparison of an image formed by differently refrangible rays.

This telescope is a very good one, as to its effect or performance, but it is not so commodious for common use as those of the Gregorian form, and is therefore now pretty much laid aside. They who would see a larger account thereof, may consult Sir Isaac Newton's Optics, and several Philosophical Transactions, where he describes it at large, and the reasons which induced him to make choice of this structure rather than that of Dr. Gregory: or see a compendious account of the whole in the last edition of Dr. Gregory's Elements of Optics.

Solar TELESCOPE. This instrument is applied to use in the following manner: AB (*fig. 9.*) represents a part of the window shutter of a darkened room, CD the frame, which, by means of a screw, contains the scioptric ball EF , placed in a hole of the said shutter adapted to its size. This ball is perforated with a hole $abcd$ through the middle; on the side bc is screwed into the said hole a piece of wood, and in that is screwed the end of a common refracting telescope GH, IK , with its object-glass GH , and one eye-glass at IK ; and the tube is drawn out to such a length, as that the focus of each glass may fall near the same point.

This being done, the telescope and ball are moved about in such a manner as to receive the sun-beams perpendicularly on the lens GH , through the cylindric hole of the ball; by this glass they will be collected all in one circular spot m , which is the image of the sun. The lens IK is to be moved nearer to or farther from the said image m , as the distance at which the secondary image of the sun is to be formed requires, which is done by sliding the tube $IKLM$ backwards and forwards in the tube $LMNO$. Then of the first image of the sun m will be formed a second image PQ , very large, luminous, and distinct.

In this manner the sun's face is viewed at any time, without offence to weak eyes; and whatever changes happen therein may be duly observed. The spots, which make so rare an appearance to the naked eye, or through a small telescope in the common way, are here all of them conspicuous, and easy to be observed under all their circumstances of beginning to appear, increase, division of one into many, the uniting of many into one, the magnitude, decrease, abolition, disappearance behind the sun's disk, &c.

By the solar telescope, we also view an eclipse of the sun to the best advantage, as having it in our power by this means to represent the sun's face or disk as large as we please, and consequently the eclipse proportionably conspicuous. Also the circle of the sun's disk may be so divided by lines and circles drawn thereon, that the quantity of the eclipse estimated in digits, may this way be most exactly determined; also the moments of the beginning, middle, and end thereof, for finding the longitude of the place: with several other things relating thereto.

The transits of Mercury and Venus over the face of the sun, are exhibited most delightfully by this instrument. They will here appear truly round, well defined, and very black; their comparative diameters to that of the sun may this way be observed, the direction of their motion, the times of their ingress and egress, with other particulars for determining the parallax and distance of the sun, more nicely than has hitherto been done.

By the solar telescope, you see the clouds most beautifully pass before the face of the sun, exhibiting a cu-

rious spectacle according to their various degrees of rarity and density. But the beautiful colours of the clouds surrounding the sun, and refracting his rays, are best seen in the picture made by the camera-glass.

The fine azure of the sky, the intensely strong and various dyes of the margins of clouds, the halo's and corona's, are this way inimitably expressed. And since the prismatic colours of clouds, so variously compounded here, make so noble and delightful a phenomenon, it is surprising that no more regard is had thereto by painters, whose clouds, though near the sun, are seldom or never seen tinged or variegated with those natural tints and colours.

Aerial TELESCOPE, is a dioptric telescope, used without a tube, in a dark night; for the use of the tube is not only to direct the glasses, but also to make the place dark where the images of objects are formed.

Huygenius contrived a telescope of this kind for viewing the celestial bodies by fixing the object-glass on the top of a long upright pole, and directing its axis towards any object by means of a silk line coming from the object-glass to the eye-glass below.

We shall here give the description of one of these telescopes. On the top of a long pole, or mast, ab (*plate CXXVI. fig. 10.*) is fixed a board moveable up and down in the channel cd ; e is a perpendicular arm fixed to it, and ff is a transverse board that supports the object-glass inclosed in the tube i , which is raised or lowered by means of the silk thread rl ; gg is an endless rope, with a weight, h , whereby the apparatus of the object-glass is counterpoised; kl is a stick fastened to the tube i ; m the ball and socket, by means of which the object-glass is moveable every way; and to keep it steady there is added a weight n suspended by a wire; l is a short wire, to which the thread rl is tied; o is the tube which holds the eye-glass; q the stick fixed to this tube, s a leaden bullet, and t a spool to wind the thread on; u is pins for the thread to pass through; x the rest for the observer to lean upon; and y the lantern. In this manner, telescopes have been constructed 123 feet long.

There are several ways of preparing a pole of a proper height, which every workman can readily employ. But as unexperienced persons cannot easily find out and follow an object with this sort of telescope, we shall shew how this may be done by means of a small machine placed upon a rest aa (*fig. 11.*) and a variable rhombus, made of brass plates bb , two of whose sides are produced, till they equal the sides of the rhombus, which is fixed at gg to the rest. From the upper angle of the rhombus, there projects a small axis about half an inch: on this axis is fixed the plate e , which upon a very small axis supports the stick and tube of the eye-glass, and the whole is counterpoised upon the axis f by proper weights b, h . Things being thus ordered, to whatever place the observer shall move the object glass, by the handle d , there it will remain at rest.

And for managing the object-glass, M. de la Hire contrived the machine represented *fig. 12.* where EF is an oblong piece of wood, of a convenient magnitude, to the ends of which are fixed two cylindrical staves GH, IK , to serve as an axis; then a hole is bored in a line with this axis, for the wooden axis SLM to pass through, with two nuts S, M . To the upper end, S , is fixed a square board AC , with a circular pole in it to receive the object-glass; and to the bottom corners of this board are fixed two wooden rulers, which meet at N , where there is a pin, R ; to which the silk thread for moving the object-glass is tied, as much below the line CD as the axis GK , which lies upon two tenter-hooks O, P . To keep off the dew from the object-glass, the same gentleman orders it to be included in a paste-board tube, made of spongy-paper, to suck up the humidity of the air: and to find an object more readily, he prescribes a broad annulus of white pasteboard to be put over the tube that carries the eye-glass; upon which the image of the object being painted, an assistant, that sees it, may direct the tube of the eye-glass into its place: or, that the observer himself may see it, he would have it received upon a ring of transparent oiled paper, pasted upon a circular frame instead of pasteboard.

Tapestry Loom for the high Warp, or that in a Perpendicular Situation.

Tapestry Loom for the low Warp, or that in an Horizontal Situation.

TELESCOPICAL STARS, such as are not visible to the naked eye, but discoverable only by the help of the telescope.

TEMACHIS, in natural history; the name of a genus of fossils, of the class of the gypsums, the characters of which are these: it is of a softer substance than many of the other genera, and of a bright and glittering hue.

The name is derived from the Greek, *τεμαχος*, *frustum*, a small irregular fragment; the bodies of this genus being composed of an assemblage of multitudes of irregular flaky fragments, as are all gypsums; but no genus of them so visible as these.

TEMPERAMENT, among physicians, denotes the same with constitution; or a certain habitude of the humours of the human body, whereby it may be denominated hot, cold, moist, dry, bilious, sanguine, phlegmatic, melancholic, &c.

According to Boerhaave, moistening, diluting, and tempering substances are a proper diet for persons of a hot and acid temperament; and, on the contrary, all heating things are prejudicial to them: whereas, in persons of a cold and moist habit, just the reverse of this obtains. To persons of a sanguineous temperament, evacuating and tempering medicines are beneficial, and heating or drastic stimulating things pernicious. Persons of a melancholy temperament are greatly injured by hot, drying, and acrid substances; whereas moistening, refrigerating, relaxing, emollient substances, and such as gently dissolve without any acrimony, are beneficial to them.

TEMPERAMENT, in music, is the rectifying or mending the imperfect concords, by transferring to them part of the beauties of the perfect ones.

In order to this, musicians take a medium between the two, which they call a temperament. Supposing then, one tone increased, and the others diminished, by half a comma, we should have our thirds major perfect: but still, it is necessary to examine, what fifths this supposition would give. Now it is evident, that a tone-major added to an octave, makes just two fifths, thus $\frac{2}{1} \times \frac{2}{1} = \frac{4}{1} = \frac{3}{2} \times \frac{3}{2}$. But the tone here added is a tone major, and the tone we have assumed is a temperate tone, deficient from the tone major by half a comma; hence the sum of the two fifths, on this supposition, will fall short of the truth by $\frac{1}{2}$ of a comma, and consequently one fifth will be deficient by $\frac{1}{4}$ of a comma. Which difference, although it be sensible, yet experience shews, that fifths so diminished are tolerable.

This is what is called the common or vulgar temperament, and consists, as has been said, in diminishing the fifth by $\frac{1}{4}$ of a comma, in preserving the third major perfect, and dividing it into two equal tones. Which being supposed, it follows that the fourth must exceed the truth by $\frac{1}{4}$ of a comma; that the third minor will be deficient by the same quantity; that the sixth minor will be perfect, and the sixth major redundant by $\frac{1}{4}$ of a comma; and lastly, that the semitone major will exceed the truth by $\frac{1}{4}$ of a comma. If we introduce chromatic notes, or flats and sharps, the semitone minor will also exceed the truth by $\frac{1}{4}$ of a comma, and consequently the difference between the two semitones, or the diesis enharmonica, will be preserved.

There are also other temperaments proposed by different authors; as that of 31 parts by Mr. Huygens; Mr. Sauver's of 43, Mr. Hensling's of 50, and that of 12.

TEMPERATURE, or *Climate for Plants*.—The difference of climate or temperature of the air has a very great effect on plants. The different degree of heat is the great cause of those changes, and the different degree of moisture somewhat assists in it. The American and Asiatic plants, famous in medicine when of the growth of their native soils, yet when removed into our climate, though they grow and even produce their flowers and ripen their seeds, which seems the last perfection of a plant, when put to the trial, have been always found to want their proper medicinal virtues.

Many of those plants and trees, which, though natives of another climate, will endure the open air with us, and grow in our gardens; yet lose much of their strength, and become dwarfs, in proportion to what they were

when in their proper climate. But much less violent changes than these are able to produce the like effects, at least in some degree. The several parts of Europe are able to alter the quality of the same plant, even while it grows naturally in them. Thus, the blue aconite or napellus, the root of which is a terrible poison in the south of France; yet in Brittany, a northern province of the same kingdom, the root of the same plant, though it seems to grow with equal vigour there, is equally large and succulent, has no bad effects; but has been eaten by old people and children without any injury.

In general, the farther north we go the less and less hurtful this plant becomes. It is common to almost all Europe, and we find the inhabitants of some places dreading it, and that, with great justice, as a fatal poison; while those of others eat the leaves in their sallads, and even esteem them good to restore the appetite.

The common wood which succeeds well in many parts of England, is not so certain in France; but the different climates, in different parts of that great kingdom, make strange alterations in its juices. In Upper Languedoc they raise great quantities of it, and it makes an extremely fine blue dye for stuffs of all kinds; but, in Brittany, though the plant grows as high, and seems to flourish as well, yet the leaves are never so succulent, and the colour obtained from them is not of so fine a blue, but is dusky and brownish.

This effect of the different climates, in changing the nature of things produced in them, is not confined to plants; but the animal kingdom shares in it. The whole serpent kind are in general larger and more venomous, as we approach the hotter climates.

The differences, made by variety of climates upon plants, are not limited to distance of place, but even in the same province the climate differs greatly in different years, by means of accidents, and more or less heat; and more or less moisture will do as much violence to plants sometimes, as change of place, which only operates by means of the same agents. Our farmers complain of great mischiefs, from long droughts; and the French husbandmen, in many of the provinces, always find, that when there has fallen very much rain, or thick fogs have been very frequent, all the bread-corn of every kind degenerates; the wheat and barley are poor and thin in the ear, and the grain small; but the rye becomes so altered, that it is pernicious to use it in making of bread; and the poor, who are obliged to eat the bread made with it, are subjected to many diseases by it. They call the rye thus vitiated *ergot* and *blé cornu*.

TEMPERING of *Steel and Iron*, the rendering them either more compact and hard, or soft and pliant, according as the different uses for which they are wanted may require.

This operation consists in plunging them, while red hot, into some liquor prepared for the purpose; sometimes in pure water, as locksmiths, &c. which seldom use any other: and sometimes a composition of divers juices, liquors, &c. is used; which is various according to the manner and experience of the workman; as vinegar, mouse-ear water, the water oozing from broken glasses, foot, salt, oil, &c. To harden and temper English, Flemish, and Swedish steel, they must have a pretty high heat given them, and then be suddenly quenched in water to make them hard: but Spanish and Venetian steel require no more than a blood-red heat before it is quenched.

If the steel be too hard or brittle for an edged tool, &c. take it down by rubbing a piece of grind-stone or whet-stone hard upon the work, to take off the black scurf: then brighten or heat it in the fire, and as it grows hotter, you will see the colour change by degrees, coming first to a straw or light gold-colour, then to a darker gold-colour, and at last to a blue colour.

Choose such of these colours as the work requires, then quench it suddenly in the water. The light-gold colour is for files, cold chisels, and punches to punch iron and steel: the dark gold-colour, for punches to use on brass, &c. the blue colour gives the temper for springs.

The tempering of files and needles is performed after a peculiar manner.

The ancients appear to have had some better method of tempering, than any the moderns are acquainted withal; witness their works in porphyry, a stone so hard that none of our tools make an impression upon it. See the article STEEL.

TEMPLARS, TEMPLERS, or Knights of the Temple, a religious military order, instituted at Jerusalem, about the year 1118; the origin of which was as follows:

Some religious gentlemen put themselves under the government of the patriarch of Jerusalem, renounced property, made the vow of celibacy and obedience, and lived like canons regular. At first, there were but nine of this order, the chief of whom were Hugo de Paganis, and Geoffrey of St. Omers. These religious having neither church nor house belonging to the society, king Baldwin gave them an apartment in his palace, which stood over-against the south gate of the church dedicated to Our Saviour. The canons of this church gave them part of their street adjoining, upon certain conditions either of rent or service. They had likewise lands given them by the king, the patriarch, and the nobility, for their maintenance; and the business of their character was to guard the roads for the security of pilgrims.

For the first nine years, they were confined to the number of nine. After this term, a rule was drawn up for them, and a white habit assigned them by pope Honorius II. And now their numbers were left at liberty, and their estates began to improve. About twenty years after, in the popedom of Eugenius III. they had red crosses sewed upon their cloaks, as a mark of distinction; and, in a short time, their number was increased to about three hundred knights, in their convent at Jerusalem; besides great numbers in other parts of Christendom, where their revenues exceeded those of many princes. They took the name of Knights Templars, because their first house stood near the church dedicated to Our Saviour at Jerusalem.

This order of knights, after having done many fine and singular actions against the Infidels, was become rich and powerful all over Europe; but the knights abusing their wealth and credit, fell into great disorders and irregularities. Two of them, who were condemned for their crimes, accused the whole order. King Philip the Fair, who hated the Templars, received the depositions of these two informers, acquainted Clement V. with it, and caused all the knights to be apprehended, on the 5th of October 1307. The king took possession of their house at Paris, and seized all the possessions they had in the kingdom.

The witnesses, who deposed against them, alleged, that the knights when they entered into that order, renounced Jesus Christ, and spit upon a crucifix: that they were addicted to sodomy; and that they worshipped a gilded wooden head, which had a long beard; and committed many other abominable and impious pranks. The knights confessed some of those crimes when they were put to the torture; and the like examinations were made in the other provinces of the kingdom. Some of the principal Templars, by the king's order, were brought to Poitiers, where the pope was, who examined them himself; and, upon their confession, commanded the ordinaries to proceed against them in their dioceses, and decreed, that their estates should be reserved for the succours of the Holy Land.

The pope and the king, having agreed to destroy the order, proceeded against them before ecclesiastical commissioners appointed by the pope. These commissioners met at Paris, in November 1309, to hear the depositions of witnesses, and the defences of the accused. Among the Templars that were brought to Paris, there were seventy-nine, who maintained the innocence of their order. Fifty-nine, who persisted in the denial of what they had confessed before, were delivered over to the secular arm, and condemned to be burnt; which sentence was executed, without St. Anthony's gate, at Paris, in March 1310. They were likewise prosecuted in Italy, in Spain, and other states. In fine, the pope, by his

bull of the 22d of May 1312, given in the council of Vienna, pronounced the extinction of the order of the Templars, united their estates to the order of St. John of Jerusalem, and remitted the judgment of particular ones to provincial councils. The king kept two-thirds of the moveables of the order, on pretence of the expence he had been at in carrying on the process against him. In Arragon, the pope united their estates to the order of Calatrava. However, the king of Arragon reserved to himself seventeen strong places, which had belonged to them. Ferdinand king of Castile united to his domain the cities, lands, and other possessions, which they had in his kingdom. Out of their estates the king of Portugal founded the order of the knights of Christ; and in England they were united to the order of the Hospitallers.

It is a question among historians, whether the knights Templars were really guilty of the crimes laid to their charge, or whether the vast estates they were possessed of were not the occasion of their ruin. As to the confession some of them made of their guilt, the advocates for their innocence impute it to the force of racks and tortures.

TEMPLE, a general name for places of public worship, whether Pagan, Christian, or otherwise. But the word in a restrained sense, is used to denote the places, or edifices, in which the Pagans offered sacrifice to their false gods. Thus we hear of the temples of Jupiter, Apollo, Bacchus, &c.

The origin of temples is not so early as that of religion. The first generations of men worshipped towards heaven in the open air. The Persians had no temples, as not thinking the god to be of human shape: which was the reason, some think, why Xerxes burnt and demolished the temples of Greece. The Greeks originally worshipped their gods upon the tops of high mountains. The same custom is attested in many places of scripture; and the antiquity of it is evident from the history of Abraham, who was commanded by God himself to offer up his son upon one of the mountains in the land of Moriah.

Who it was that erected the first temple, is not agreed by ancient writers. Some ascribe it to Phoroneus the Egyptian, others to Merops, and others to Æacus the son of Jupiter, &c. Many are of opinion, that temples owe their first rise to the superstitious reverence paid by the ancients to their deceased friends; and as most of the gods were men deified on account of their great virtues, so temples are thought to have been no more, at first, than stately monuments erected in honour of the dead. Nor is it any wonder, that monuments should at length be converted into temples, when at every common sepulchre it was usual to offer prayers, sacrifices, and libations.

Temples were built and adorned with all possible splendor and magnificence, partly out of the great respect they bore to the gods, and partly to create an awe and reverence in the worshippers. They were constructed in the manner which was thought most agreeable to the gods, to whom they were dedicated. Thus Jupiter, they thought, took most delight in pillars of the Doric order; Bacchus in the Ionic; and Vesta in the Corinthian: though this rule was not universally or constantly observed. As to the places where temples were built, they made choice of these with a view to the disposition of particular deities. Hence some were erected on the tops of mountains, others in vallies, and others in cities. Those built in the country were generally surrounded with groves sacred to the tutelar deity of the place; and wherever they stood, it was so contrived, that the windows being opened might receive the rays of the rising sun. The most ancient situation was with the front towards the west, and the altars and statues at the east end, it being a custom among the Heathens to worship with their faces towards the east. But, in after ages, they placed the front of temples towards the east, so as that the doors being open should receive the rising sun. If the temples were built by the side of a river, they were to look towards the banks of it: if near the highway, they were so situated that travellers might have a fair

a fair prospect of them, and pay their devotion as they passed by.

Temples were divided into two parts: the one called *Adytum*, *Alytum*, which was the inmost recess of the building, and deemed so sacred, that none but the priests were allowed to enter into it: the other was open, and free to all, who came to pay their worship. In the middle of the temples stood the images of the gods, on pedestals raised above the height of the altar, and enclosed with rails.

Temples, according to the number and difference of their columns, were divided into tetrastyle, prostyle, amphiprostyle, periptere, diptere, &c.

Tetrastyle TEMPLE, was a temple that had four columns in front, and as many behind,—as the temple of Fortuna Virilis at Rome.

Prostyle TEMPLE, that which had only columns in its front or fore-side,—as that of Ceres, at Eleusis, in Greece.

Amphiprostyle, or Double prostyle TEMPLE.—That which had columns both before and behind, and which was also tetrastyle.

Periptere TEMPLE, that which had four rows of insulated columns around, and was hexastyle, that is, had six columns in front,—as the temple of Honour at Rome.

Diptere TEMPLE, that which had two wings, and two rows of columns around, and was also octostyle, or had eight columns in front,—as that of Diana at Ephesus.

TEMPLES, among us, denote two inns of court, thus called, because formerly the dwelling-house of the knights Templars.

TEMPLES, Tempora, in anatomy, a double part of the head, reaching from the forehead and eyes to the two ears.

TEMPORAL, a term generally used for secular, as a distinction from ecclesiastical. Thus we say temporal lords, and spiritual or ecclesiastical lords.

TEMPORALIS, in anatomy. See the article *CROTAPHITES*.

TEMPORIS Os, in anatomy, a bone on each side the head, thus denominated from its situation in the temples.

The figure of the os temporis is nearly circular; the fore and upper parts are very thin, consisting only of one table; the lower and hind parts are thick, hard, and uneven.

It is joined to the os sincipitis by the squamous suture, whence in that part it is called os squamosum; its lower part is joined to the os occipitis and sphenoides, to which latter, as likewise to the bones of the upper jaw, it is joined by means of certain processes, and in that part is called os petrosum.

Each of the ossa temporum has two sinus's, the exterior of which is lined with a cartilage and receives a process of the lower jaw; the interior receives the lower part of the sinus lateralis of the dura mater. Each likewise has four processes; the os jugale, processus mammillaris, styloides, and os petrosum.

TENAILLE, in fortification, a kind of out-work, resembling a horn-work, but generally somewhat different; for instead of two demi-bastions, it bears only in front a re-entering angle betwixt the same wings without flanks, and the sides are parallel.

Tenaille double or flanked, is a work, whose front consists of four faces, making two re-entering angles, and three salient; the wings or sides of this work being in like manner correspondent in the front of the gorge.

Tenaille simple, a work having its front formed by two faces, which make a re-entering angle, the sides running directly parallel from the head to the gorge.

Tenaille of the place, is that which is comprehended between the points of two neighbouring bastions; that is to say, the curtain, the two flanks that are raised on the curtain, and the two sides of the bastions which face one another, so that it is the same with what is otherwise called the face of the fortress.

Tenaille of the foss, is a low work raised before the curtain in the middle of the foss: it is of three sorts; the first is composed of a curtain, two flanks, and two

faces; the rampart of the curtain, including the parapet and talus, is but five fathom thick, but the rampart of the flanks and faces is seven. The second is composed only of two faces made on the lines of defence, whose rampart and faces are parallel. The third sort differs from the second, only in this, that its rampart is parallel to the curtain of the place. All three sorts are good, and cannot be hurt by the besiegers cannon, till they are masters of the covert-way, and have planted their cannon there.

All tenailles are defective in this respect, that they are not flanked or defended towards their inward or dead angle; because the height of the parapet hinders seeing down before the angle, so that the enemy can lodge himself there under covert: wherefore tenailles are never made but when they want time to make a horn-work.

TENANT, or TENENT, in law, one that holds or possesses lands or tenements of some lord or landlord, by any kind of right, either in fee, for life, years, or at will. The term tenant is used with divers additions.—Thus,

TENANT in Dower, is she that possesses lands by virtue of her dower.

TENANT per Statute Merchant, he that holds lands forfeited to him by virtue of a statute.

TENANT in frank Marriage, is he that holds lands or tenements by virtue of a gift thereof made to him upon marriage between him and his wife.

TENANT by Courtesy, holds for his life by reason of a child begotten by him of his wife, being an inheritrix, and born alive.

TENANT by Elegit, holds by virtue of the writ called an elegit.

TENANT in Mortgage, holds by means of a mortgage.

TENANT by Verge, in ancient demesne, is he who is admitted by the rod in court to lands of ancient demesne.

TENANT by Copy of Court-roll, is one admitted a tenant of any lands, &c. within a manor, which time out of mind has been demised according to the custom of the manor.

TENANT by Charter, is he that holdeth by feoffment in writing or other deed.

TENANT in Capite, or Chief, holdeth of the king in right of the crown.

TENANT of the King, is he that holdeth of the person of the king.

Joint TENANTS, those who have equal right in lands and tenements by virtue of one title.

TENANTS in common, those who have equal right, but hold by divers titles.

Particular TENANT, is he that holds only for his term.

Sole TENANT, is he who hath no other joined with him.

TENANT by Execution, is he who holds by virtue of an execution upon any statute, recognizance, &c.

TENANT, or TENAN, in heraldry, is used for something that sustains or holds up the shield, or armory, and is generally synonymous with supporter.

TENAR, in anatomy. See the article *THENAR*.

TENCH, in ichthyology, the English name of the tinca of modern authors, the fullo and gnaphus of the ancients.

It is, according to the Artedian system, a species of the cyprinus, and distinguished by that author by the name of the blackish, mucous, or slimy cyprinus, with the end of the tail even.

This is a delicately tasted fish, though it lives in foul water and seems to feed very coarsely. It is always found in the muddiest parts of ponds, and where there are most weeds.

The slime of the skin of this fish is said to be of a healing nature, and to cure all fresh wounds; and it is pretended that the other fish know this property in it, and always apply to the tench when wounded. Whether their opinion be true or false, the tench has obtained by it the name of the fishes physician. The pike is said to pay such respect to this fish, on this account, that he

never seizes him. But these are things easier to be fancied and said than proved; and, if it should prove that the pike does not eat the tench, it may be resolved into a much more natural cause, by supposing the stime of the tench too disagreeable in his stomach to suffer it.

The season for angling for tench is in June, July, and August. The time of their biting is early in the morning, or late in the evening, and, in hot weather, all night long. The favourite bait for the tench is a large red worm, and they will take this much more greedily, if it be dipped in tar, after it is put on the hook. There are several sorts of paste also that he bites very well at, particularly one made of brown bread and honey, with an admixture of tar. All pastes that have any of the strong-scented oil in them, are also good baits. Other baits are the cad-worm, lob-worm, flag-worm, green-gentle, marsh-worm, or soft-boiled bread corn. All these will do very well at a proper season.

When any number of tench are to be taken out of a muddy pond, where they will not bite freely at the hook, the method is to take a very good and large casting-net, well leaded, and with the meshes from the crown to a full yard and a half, not too small; for then if the pond be deep, the fish will strike away before the net gets to the bottom. The place where the net is intended to be thrown, must be made clean from bushes and large weeds with a rake. When the place is thus cleared of any obstacles to the even descent of the net, a bait is to be prepared to draw the fish together, where the net is to be thrown. This bait is to be thus made: Put a quarter of a peck of wheat into three quarts of water, send it to an oven, and let it be well soaked: then add to it five pints of blood, and as much bran as is necessary to give it the consistence of a paste. Mix some clay with it, that it may the better hold together; and finally, add a quart of lob-worms chopped to pieces. Let the whole be wrought up into a stiff paste, and rolled into balls of the size of a hen's egg; and let these be thrown into the pond, in the place where the net is to be thrown. At times these, and at times some grains, are to be thrown in; and the place in this manner thoroughly baited for several days. When the fish may be supposed to be very well acquainted with the spot, let a very good baiting be given in the morning, and in the close of the evening let the casting-net be carefully thrown in. When the net is sunk, the mud all about is to be stirred up with a long pole, with a fork at the end; the net is to lie half an hour, and the mud to be thus stirred all the time; by this means the tench will be raised, and will be taken in the pulling out the net; but, if the net were to be thrown in and taken out in the common way, there would hardly be one fish taken; for the custom of both tench and carp, when they are frightened, is to plunge their heads up to eyes in the mud, and thus placed, with their tails erect, any net in the world must draw over them, without a possibility of its entangling them.

TENDER, in a legal sense, signifies as much as to offer or endeavour the performance of any thing, in order to save the penalty or forfeiture incurred by non-performance.

TENDERS, in the sea language, are vessels employed to raise seamen for the navy, commanded by a lieutenant of one of his majesty's ships; they likewise attend large ships, and carry stores, &c.

TENDON, *Tendo*, in anatomy, that hard, white, extreme part of a muscle, whereby it is fastened to the bone. See **MUSCLE**.

TENEBRÆ, an office in the Romish church, performed on Wednesday, Thursday, and Friday, in Passion Week, at which time, neither flowers nor images are allowed to be set upon the altars, but they must be covered with purple.

TENEMENT properly signifies a house; but in a larger sense it is taken for any house, land, rent, or other thing, which a person holds of another.

TENEMENTARY LANDS, such as are held by the tenant, distinguished by that name from the demesne land of the lord, called inland.

TENEMENTIS LEGATES, a writ that anciently lay to the city of London, or any other corporation, where, according to the old custom, men might devise tene-

ments, as well as goods and chattels, by their last will; for the determining of any controversy relating thereto, and for rectifying the wrong tenant.

TENENTIBUS IN ASSISA NON ONERANDIS, a writ which lies for the person to whom a disseisor has aliened the land whereof he disseised another; that he be not arrested on the damages awarded on the assize, if the disseisor has wherewith to satisfy them himself.

TENESMUS, in medicine, a name given by medical writers, to a complaint which is a continual desire of going to stool, but without any stool being ready to be voided. This is usually attended with some tumour, sometimes with a very considerable one in the part. This is properly no primary disease, but merely a symptomatic one, and differs in degree according to the disease on which it is an attendant. Signs of it are a titillation and itching about the anus, attended with a violent burning pain, and a desire of compressing and voiding something, and this attended usually with no excrement, or only a pulposus or mucous matter, and very often prolapsus ani, or falling down of the rectum. This disease happens often to people labouring under hæmorrhoidal disorders, especially when the discharges attending them do not succeed regularly, though nature gives all the necessary motions for their excretion. It happens also to people who are subject to void an acrid and bilious matter by stool, and not unfrequently to those who have a stone in the bladder. Women in the latter part of their time in going with child, have also very often terrible fits of it, attended with considerable swelling; this happens to them from the pressing of the uterus with its burden, upon the rectum and hæmorrhoidal veins. The causes of a tenesmus, besides those already mentioned, are the ascarides, a small sort of worms, which usually infest the rectum, and occasion a continual itching and tickling there; the abuse of resinous purging medicines. Much riding will also sometimes occasion it.

As the tenesmus is merely a symptomatic disease, the primary disorder is first to be examined, and treated in order to a cure; thus, when it is occasioned by ascarides, worm medicines are to be given, and clysters of a proper kind injected; and when the worms are by this means destroyed, the tenesmus, which was no more than a symptom, naturally ceases. In general, the regimen and method of cure in a tenesmus, are the same with those prescribed in a dysentery; great relief is afforded by a fomentation of warm milk, in which elder-flowers have been boiled, as also by a clyster of mutton broth, or an emollient clyster, in which earth-worms have been boiled. The medicines, at present, generally used for the cure of a tenesmus, are these following: take of pulvis sanctus and rhubarb, each one scruple; of the oil of cinnamon, one drop; of London laudanum, half a grain; and of the syrup of violets, a sufficient quantity for making into a bolus, to be taken in the morning, and repeated as the situation of the patient requires; at night a paregoric may be exhibited, and clysters afterwards used; for which purpose, take of whey, or mutton-broth, four ounces; of canary wine, two ounces; of gum arabic, half an ounce; of gum tragacanth, one dram; and of crude opium, two grains; make into a clyster, to be injected twice or thrice a day, afterwards continue the following medicine for some time: Take of the confection of Fracastorius, without honey, one scruple; of sperma ceti, fifteen grains; of the species of hyacinthæ, japan earth, red coral, and American bole, each eight grains; of the oil of nutmegs, one drop; and syrup of red roses, a sufficient quantity for making a bolus, to be taken twice a day, in a small quantity of the tincture of red roses. In a tenesmus, the last refuge is to opiates.

TENET, or **TENENT**, a particular opinion, dogma, or doctrine, professed by some divine, philosopher, &c.

TENNE, **TENNY**, or **TAWNY**, in heraldry, a bright colour made of red and yellow mixed; sometimes also called brusk, and expressed in engraving, by thwart, or diagonal strokes or hatches, beginning from the sinister chief, like purple, and marked with the letter T. In the coats of all below the degree of nobles, it is called tenny; but in those of nobles it is called hyacinth; and in princes coats, the dragon's head.

TENON,

TENON, in building, &c. the square end of a piece of wood, or metal, diminished by one third of its thickness, to be received into a hole in another piece, called a mortise, for the jointing or fastening the two together. It is made in various forms, square, dove-tailed for double mortises, and the like.

TENOR, or **TENOUR**, the purport or content of a writing or instrument in law, &c. An action of debt brought upon a judgment in an inferior court, where the defendant pleads, *nul tiel record*, no such record, a tenor thereof only shall be certified; and it likewise is the same on certioraris. A tenor of a libel has been held to be a transcript of it.

TENOR, or **TENORE**, in music, the first mean, or middle part, or that which is the ordinary pitch of the voice, when neither raised to a treble, or lowered to a bass. The tenor is commonly marked in thorough bass with the letter T. This is that part which almost all grown persons can sing; but as some have a greater compass of voice upwards, others downwards, others are confined to a kind of medium, and others can go equally high or low; hence musicians make a variety of tenors, as a low, a high, a mean, a natural tenor, to which may be added, a violin tenor, &c. for instruments. The Italians usually distinguish two kinds of tenor, *tenore primo*, 1^o or P^o, which answers to our upper tenor; and *tenore secundo*, 2^o or II^o, which is our natural tenor, confounding the counter-tenors, &c. under the name of baritone.

TENSE, **TIME**, in grammar, an inflexion of verbs, whereby they are made to signify or distinguish the circumstance of time of the thing they affirm or attribute.

The affirmations made by verbs are different, as to the point of time; since we may affirm a thing is, or was, or will be, hence, a necessity of a set of inflexions, to denote those several times, which inflexions our English grammarians call by a barbarous word tenses from the French *temps*; most other languages call them simply times.

There are but three simple tenses; the present, as I love, *amo*; the preter, preterit, or past, as I have loved, *amavi*; and the future, as I will love, *amabo*.

But, in regard, in the preter tense, one may either express the thing as just done, or past, or indefinitely, and barely that it was done; hence, in most languages arise two kinds of preterits; the one definite, marking the thing to be precisely done, as I have written, I have said; and the other indefinite, or aorist, denoting a thing done indeterminately, as I wrote, I went. The future tense admits of the same variety. Besides the three simple tenses, others have been invented, called compound tenses, expressing the relation of simple ones to each other. The first expresses the relation of the past to the present, and is called the preterimperfect tense, because it does not mark the thing simply and properly as done, but as imperfect, and present with respect to another thing past; as I was at supper, when he entered, *Cum intravit, cenabam*.

The second compound tense marks the time past doubly, and is therefore called *plusquam* perfect tense, as I had supped, *cenaveram*.

The third compound tense denotes the future, with respect to the past; as I shall have supped, *cenavero*.

The several tenses or times, it is to be observed, are properly denoted in the Greek and Latin by particular inflexions; in the English, French, and other modern tongues, the auxiliary verbs to be and to have, *etre* & *avoir*, are called in.

As to the Oriental languages, they have only two simple tenses, the past and future, without any distinction of imperfect, more than perfect, &c. which renders those languages subject to abundance of ambiguities, which others are free from.

TENSION, *Tensio*, the state of a thing bent, or the effort made to bend it.

Animals only sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acuter or deeper sound, as it is in a greater or less degree of tension.

TENT, a pavilion or portable lodge.

TENT, in surgery, a roll of lint worked into the shape of a nail, with a broad flat head. Tents differ in thickness and length, according to the size of the wound for which they are intended, and are chiefly used in deep wounds and ulcers. They are of service not only in conveying medicines to the most intimate recesses and sinuses of the wound, but to prevent the lips of the wound from uniting, before it is healed from the bottom; and by their assistance grumous blood, fordes, &c. are readily evacuated. They ought to be made extremely soft, that the cure of the wound may not be retarded by the pain they would otherwise bring on.

There is another kind of tents made of linen rags not scraped, and worked up into a conical form, to the basis of which is fastened a long thread; the apex of this tent must be a little unravelled, to make it softer, lest it may become painful: the thread is fastened to the basis, that the tent may be recovered with the greater ease, if, by any accident, it should be forced into the cavity of the thorax or abdomen; for the tents we now describe, are chiefly used to keep open wounds that penetrate into the cavity of the thorax or abdomen, in order to make way for the proper discharge of blood, matter, &c. There is a third sort of tents, which serve not only to keep open, but to enlarge, by degrees, the mouth of any wound or ulcer which shall be thought too strait; that, by this means, a free passage may be procured for the blood and matter that were confined, and that proper medicines may find a more ready admittance. These tents are made either of sponge, prepared in a certain manner; or of dried roots of gentian, calamus aromaticus, &c. for their substances imbibe the matter which flows to them, and being presently enlarged dilate the lips of the wound.

TENTER, **TRIER**, or **PROVER**, a machine used in the cloth manufactory, to stretch out the pieces of cloth, stuff, &c. or only to make them even and set them square.

It is usually about four feet and a half high, and for length exceeds that of the longest piece of cloth. — It consists of several long square pieces of wood, placed like those which form the barriers of a manege, so, however, as that the lower cross piece of wood may be raised or lowered, as is found requisite, to be fixed at any height by means of pins. — Along the cross pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

To put a Piece of Cloth on the TENTER: While the piece is yet quite wet, one end is fastened to one of the ends of the tenter; then it is pulled by force of arms towards the other end, to bring it to the length required: that other end being fastened, the upper list is hooked on to the upper cross piece, and the lowest list to the lower cross piece, which is afterwards lowered by force till the piece have its desired breadth. — Being thus well stretched, both as to length and breadth, they brush it with a stiff hair-brush, and thus let it dry. — Then they take it off; and, till they wet it again, it will still retain the width and breadth the tenter gave it.

TENURE, in law, the manner or condition wherein a tenant holds lands or tenements of his lord; or the services performed to the lord, in consideration of the use and occupancy of his lands.

TEPID, in natural history, a term used by writers on mineral waters, to express such of them as have a less sensible cold than common water.

They distinguish all the medicinal springs into three kinds; the hot, the tepid, and the cold; but the middle term might easily be understood to mean a great deal more than they express by it; all that have what can be called the least sensible warmth, are called hot; and the tepid are distinguished from the absolutely cold, only by their being less cold.

Some of this class of mineral waters, and some few also of the cold ones, have a sharpish vinous taste, which is never observed in any of the hot ones. This taste is lost on the giving the waters the slightest heat, and is therefore very difficult to be guessed at as to its origin. It is not only found in the aluminous and vitriolate waters, but also in those which are manifestly nitrous, and which abound in sulphureous salts, quite different in their nature

ture from acids. It is therefore an additional somewhat, quite distinct from the saline properties of the fluid, and as easily connected with one kind of that as with the others.

The causes of heat in the mineral waters remain yet wholly unknown, notwithstanding all that has been written concerning them. It is hard to believe, that there are continual subterranean fires near enough the surface, to give a heat that preserves itself in so great a degree to the very place of their eruptions; and it is equally hard to conceive, that there can be beds of fermenting mineral matters, sufficient in quantity and force to have given the same degree of heat to waters for so many ages, as some of our hot springs are known to have subsisted. *Duclos's Exam. des Eaux Miner.*

TEREBINTHUS, the turpentine tree. See **TURPENTINE**.

TEREDO, a name given by naturalists to a species of sea-worm, which eats its way into the bottoms of ships, lining the hole it makes with a kind of shelly matter.

The head of this creature is well prepared by nature for the hard offices it is to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech; by which it pierces wood, as that animal does the skin. A little above this it has two horns, which seem a kind of continuation of the shell. The neck is as strongly provided for the service of the creature as the head, being furnished with several strong muscles. The rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and, by means of the microscope, several other very remarkable particulars become visible there.

At that part where the intestines end, the tail begins; this is longer than all the rest of the body; it is depressed in the middle, and puffed out on each side, and is joined to the callous part of the lower end of the body in an irregular manner, so that there is an intermediate void space left between: this occupies the middle part between what the natural historians call two soleæ-form fins. This creature is wonderfully minute, when newly excluded from the egg, and at its utmost bigness is a foot long; three or four inches is however its more frequent length.

The skin of this little animal being stripped off, the heart, stomach, and intestines come plainly in view, as also the callous muscles of the neck, and two white ovaries; the heart is composed of two pyramidal vessels.

TERES, in anatomy, a name given to two muscles of the arm; one is called *teres major*, and is one of the depressor muscles, which has its origin at the lower angle of the scapula, and its termination three fingers below the head of the humerus: the other is called *teres minor*, being one of the abductor-muscles, and having its origin at the inferior costa of the scapula; this, together with the *infraspinatus*, properly forms one conjunct muscle, having at the extremity, only a single tendon, which is inserted into the posterior part of the neck of the humerus.

TERM, *Terminus*, in general, signifies much the same with boundary or limit.

TERM, in law, is generally taken for a limitation of time or estate; as a lease for term of life, or years, which is deemed a chattel real.

Term, however, is more particularly used for that time wherein our courts of justice are open; in opposition to which, the rest of the year is called vacation. There are four of these terms in a year, viz. 1. Hilary-term, which begins on Jan. 23. but if that is a Sunday, the next day, and ends on Feb. 12. 2. Easter-term, which begins the Wednesday fortnight after Easter-day, and ends the Monday next after Ascension-day. 3. Trinity-term, which begins on the first Friday after Trinity Sunday, and ends the Wednesday fortnight after. 4. Michaelmas term, which begins on Nov. 6. and ends the 28th of the same month.

It has been held, that courts do not sit except in term-time, as to giving of judgments, &c. and in every term there are four days, thus distinguished; that is, the effoin-day, the day of exceptions, the day of return of

writs, and day of appearance. On the effoin-day the term is said to begin, when one judge sits in each of the courts of Westminster, in order to take and enter effoins: but it is not till three days afterwards, that all the judges sit for the dispatch of business. There are likewise different returns in different terms, some having more, some fewer: and as, in the king's bench, all returns are to be made on some particular day of the week in each term, care must be taken not to make the writs out of that court returnable on a non-judicial day, as Sunday, All-Saints, &c.

Oxford-TERMS. Hilary, or Lent-term begins on Jan. 14. and ends the Saturday before Palm-Sunday. Easter-term begins the tenth day after Easter, and ends the Thursday before Whitsunday. Trinity-term begins the Wednesday after Trinity-Sunday, and ends after the act, sooner or later, as the Vice-Chancellor and convocation please. Michaelmas-term begins on Oct. 10. and ends Dec. 17.

Cambridge-TERMS. Lent term begins on Jan. 13. and ends the Friday before Palm Sunday. Easter-term begins the Wednesday after Easter-week, and ends the week before Whit-Sunday. Trinity-term begins the Wednesday after Trinity-Sunday, and ends the Friday after the commencement. Michaelmas-term begins Oct. 10. and ends Dec. 16.

Scottish-TERMS. In Scotland, Candlemas term begins Jan. 23, and ends Feb. 12. Whitsuntide-term begins May 25, and ends June 15. Lammas-term begins July 20, and ends Aug. 8. Martinmas-term begins Nov. 3, and ends Nov. 29.

TERM, in grammar, denotes some word or expression of a language.

TERM in the arts, or **TERM of art**, is a word which, besides the literal and popular meaning which it has, or may have, in common language, bears a further and peculiar meaning in some art or science.

TERM, in logic. A proposition is said to consist of two terms, i. e. two principal and essential words, the subject, and the attribute.

TERMS of an Equation, in algebra, are the several names or members of which it is composed, and such as have the same unknown letter, but in different powers or degrees: for if the same unknown letter be found in several members in the same degree or power, they shall pass but for one term.

As in this equation, $xx + ax = bb$; the three terms are xx , ax , and bb . Moreover, in this, $x^4 + x^3 + x^2 + \frac{ab}{cd}x + \frac{fp}{rs}x + yy = 0$; the terms are x^4 , x^3 , x^2 , $\frac{ab}{cd}x$, $\frac{fp}{rs}x$, and yy . Where $\frac{ab}{cd}x$, and $\frac{fp}{rs}x$, are the same terms; and the first term in any equation must be that where the unknown root hath the highest dimensions; and that term which hath the root in it, of one dimension of power lower, is called the second term, and so on.

TERMS of Proportion, in mechanics, are such numbers, letters, or quantities, as are compared one with another.

Thus, if $2 : 4 :: 8 : 16$, then a, b, c, d , or $2, 4, 8, 16$, are called the terms; a being the first term, b the second term, &c.

TERMS, or **COURSES**, in medicine, the menses, or womens monthly purgations. See **MENSES**.

TERMINATION, *Terminatio*, in grammar, the ending of a word, or last syllable thereof.

It is the different termination of one and the same words on different occasions, that constitute the different cases, numbers, tenses, and moods, &c.

TERRA, EARTH, in geography and astronomy. See **EARTH**.

TERRA FIRMA, in geography, is sometimes used for a continent, in contradistinction to islands.

Thus Asia, the Indies and South America, are usually distinguished into *terra firmas* and islands.

TERRA A TERRA. Gallies, and other vessels are said to go *terra a terra*, when they never go from the coasts.

The

The phrase is also applied, in the manege, to horses which neither make curvets nor balotades, but run smoothly on the ground, on a pressed gallop, only making little leaps or risings with the fore feet.

TERRÆ-FILIUS, son of the earth, a student in the university of Oxford, formerly appointed, in public acts, to make jesting and satirical speeches against the members thereof, to tax them with any growing corruptions, &c.

TERRA VERTE, in natural history, a native earth, which in all probability is coloured by copper.

It is of a blue green colour, much of that tint which is called sea-green. What we have in common here, is not very bright, but being semi-transparent in oil, and of a strong body in water, and standing equally well with the best pigments, it is very much adapted to answer some purposes in both kinds of painting; though it is not so generally used by those to whom it would be serviceable as it merits. Mr. D'Acosta says, in his book of Fossils, that there is a kind which is very bright, and is found in Hungary: if it could be procured here, it would certainly be a very valuable acquisition to oil painting; as the greens we are forced at present to compound from blue and yellow, are seldom secure from flying or changing.

Terra verte, as brought from abroad, is of a very coarse texture; and requires to be well levigated, and washed over: but no other preparation is necessary previously to its use. The only method of distinguishing its goodness is by the brightness and strength of its colour.

TERRACE, or **TERRAS**, a walk or bank of earth, raised on a proper elevation, so that any person who walks round a garden, may have a better prospect of all that lies round him; and these elevations are so necessary, that those gardens which are flat, and that have them not, are deficient.

When the terraces are rightly situated, they are great ornaments, especially when they are well made, and their ascent not too steep.

There are several kinds of terrace walks. 1. The great terrace, which generally lies next to the house. 2. The side terrace, which is commonly raised above the level of the parterre, lawn, &c. 3. Those terraces which encompass a garden.

As to the breadth of side terraces, this is usually decided by its correspondence with some pavilion, or some little jettee or building; but most of all by the quantity of stuff that is to spare for those purposes.

The side terrace of a garden ought not to be less than twenty feet, and seldom wider than forty.

As for the height of a terrace, some allow it to be but five feet high, but others more or less, according to their fancies; but more exact persons never allow above five or six feet, but in a small garden, and a narrow terrace walk, three feet; and sometimes three feet and a half high are sufficient for a terrace twelve feet wide, and four feet are sufficient for a terrace of twenty feet wide; but when the garden is proportionably large, and the terrace is thirty or forty feet wide, then it must be at least five or six feet high.

The noblest terrace is very deficient without shade, for which elm-trees are very proper; for no seat can be said to be complete, where there is not an immediate shade almost as soon as out of the house, and therefore these shady trees should be detached from the body and wings of the edifice. *Miller's Gard. Dict.*

TERRACE is also applied to the roofs of houses that are flat, and whereon one may walk; as also to balconies that project.

TERRAQUEOUS, in geography, an appellation given to our globe, because consisting of land and water. See **EARTH** and **SEA**.

TERRE-PLEIN, in fortification, denotes the horizontal superficies, or top, of the rampart, between the inferior talus and the banquette. It is thus called, as lying nearly level, with only a little slope inwardly, to bear the recoil of the cannon.

TERRELLA, *μινερση*, an appellation given to a loadstone, when turned into a spherical figure, and is placed so, that its poles and equator, &c. correspond to the poles and equator of the world; as being a just re-

presentation of the great magnetical globe which we inhabit.

Such a terrella, if nicely poised and placed in a meridian, it was imagined, would turn about its axis once in twenty-four hours; but experience has shewn this to be a mistake.

TERRESTRIAL, something partaking of the nature of earth, or belonging to the globe of the earth: thus we say, the terrestrial globe, line, &c. See **GLOBE**, **EARTH**, **LINE**, &c.

TERRITORY, in geography, denotes an extent or compass of land, within the bounds or belonging to the jurisdiction of any state, city, or other subdivision of a country.

TERTIAN, in medicine, an ague, or intermitting fever, the fits of which return every third day; that is, there are two fits in three days, the day intervening being without any fit at all.

A regular tertian is attended with the following symptoms: at first, the head aches, the limbs seem weary, there is a pain in the loins about the first vertebrae of the back, which tends towards the epigastrium, with a painful sensation of a tension in the hypochondria, and costiveness: then comes on a coldness of the external parts, especially of the nose and ears, a stretching, yawning, shivering, and shaking, sometimes so much as to make the bed tremble under them; the pulse is small, contracted, and weak; sometimes the patient is troubled with thirst; then follows a nausea, with a fruitless reaching to vomit: and to these symptoms there succeeds an anxious burning and dry heat, which pervades the whole body; the pulse becomes full and thick, the restlessness increases, the breathing is more difficult, and the patient, with his eyes almost closed, begins to talk a little wildly. However, the duration of the fit is uncertain, continuing sometimes ten or eleven hours, and sometimes twenty-four.

As to the method of cure, it differs but little from that recommended for quartans. See the articles **QUARTAN** and **INTERMITTENT**.

TERTIATE a great Gun, in gunnery, is to examine the thickness of the metal at the muzzle; whereby to judge of the strength of the piece, and whether it be sufficiently fortified or not. This is usually done with a pair of caliber-compasses, and if the piece be home-bred, the diameter less by the height, divided by 2, is the thickness at any place.

TESSELATED PAVEMENTS, those of rich Mosaic work, made of curious square marbles, bricks, or tiles, called tessellæ, from their resembling dice.

TEST, in metallurgy, a vessel of the nature of the coppel, used for large quantities of metal at once.

Tests are usually a foot and a half broad, and are made of wood ashes, not prepared with so much care as for coppel making, and mixed with finely powdered brick-dust; these are made into the proper shape either by means of an earthen vessel of proper dimensions, or only an iron-ring. To make them in the first manner, an earthen vessel is to be procured, not glazed within, and by its depth and breadth proportioned to the quantity of metal to be worked: the inside of this vessel is to be well moistened with fair water, that the ashes to be put into it may adhere the better. Put into this vessel, thus prepared, the ashes and brick-dust beforementioned, and first moistened either with water alone, or with water with a little white of an egg mixed in it: let the quantity of this be so much as will half fill the vessel, then press the mass with a wooden indented pestle; or, if not for a very large test, with a wooden cylinder only of an inch thick: when thus pressed down add fresh ashes, and press them in a second time, as in the making of coppels, and repeat this addition of fresh ashes till the earthen vessel is nearly full; then remove the superfluous ashes with an iron-ruler, and let the inequalities remaining at the border, be smoothed with a wooden ball rolled round about. This done, you are to cut the cavity with a bowed iron, that you may have a broad spherical segment, not very deep: and lastly, by means of a sieve, strew this cavity carefully and regularly over with dry ashes of bones of animals, ground extremely fine, and squeeze these hard in, by the rotation of the wooden ball. Thus you have

a test

a test finished, which, together with its earthen pot, must be set in a dry warm place.

To make the tests in the other manner, or by means of an iron-ring; let a ring of that metal be filled with ashes, mixed with brick-dust, and moistened as before-mentioned, in such manner that they may rise considerably above the ring; then press them strongly, either with your hands, or with an indented pestle, and afterwards, with gentle blows of a rammer, press the ashes from the circumference towards the center, in a spiral line, and that in such a manner, that, after having been sufficiently pressed, they may be a small matter higher than the brink of the ring. If there are now any vacancies in the mass, empty the ring, and fill it again with more ashes; for, if you should attempt to fill up these by adding were it but ever so little ashes, the second or additional quantities will never cohere so firmly with the first, but that they may probably separate in the operation. This done, turn the ring upside down, and on the other side, or bottom, take out the ashes to the quantity of one third part of the depth of the ring; and again fill the vacuity with the same ashes, in such a manner that there may remain no sensible cavity. When the mass is thus prepared, cut out a cavity in the larger surface of the ring, with a bowed iron, as in the former method.

TEST-LIQUOR, a liquor used by dealers in brandies, to prove whether they be genuine, or mixed with home-spirits.

The people who use this, place great confidence in it, but it is really a very vague and uncertain thing. They pretend, that this liquor will shew by the colour which it makes, on being poured into brandy, whether it be genuine and unadulterated; or, if not, in what proportion the adulterating spirit is mixed with it.

The whole fact is this: if a little common green or white vitriol be dissolved in some fair water, it makes a test liquor; a few drops of which, being let fall into a glass of old French brandy, will turn the whole to a purple, or fine violet colour; and, by the strength or paleness of this colour, the dealer judges the brandy genuine or mixed, in different proportions, with home spirits.

Old French brandy, having long lain in the cask, takes a dilute tincture of the wood of the cask, that is, of oak; and this, being of the same nature with a solution or tincture of galls, naturally turns bluish or blackish with vitriol. A new distilled brandy, though wholly foreign, would not give this test; and a common malt-spirit, with oak chips infused in it, will turn as dark as the finest brandy. While our distillers indeed had nothing in use for the colouring their spirits but burnt sugar, it was possible to make some guess at an adulteration with them, because the brandy, in this case, would not become blackish in proportion to its former colour, the sugar-colour not turning to ink with the vitriol like the other; but our distillers have of late found a way of using an extract of oak for the colouring of their spirits, and, since that, this test liquor is of very little use, our common spirits, of any kind, turning as deep with it as the foreign brandies.

The very best way of making this test liquor is with a calcined vitriol of iron, dissolved in a dilute or aqueous mineral acid. The liquor, when well made in this manner, is of a fine yellow colour, and will give, for a time, the finest blue to any spirituous tincture of oak.

The English were, at one time, very fond of high-coloured brandies, and it was then that the use of this test liquor was most esteemed; afterwards we, as well as other nations, finding that this colour was only owing to the cask, began to dislike it, and to favour the pale brandies; at length we fell into the use of such as were wholly limpid and colourless, and the redistilling of all the old brandies people were possessed of took place; on this, the test liquor was found to be of no use at all, and accordingly rejected; but as we are of late again come into the esteem of coloured brandies, and that with great justice, as the colour, when genuine, is a certain mark of the age of the liquor, this test liquor is again got into more credit than it deserves.

The famous Helvetian styptic depended wholly on this accident for its colour; and it was no small mortification to our chemists, when, some years ago, it was introduced into use among us, that they could not make it with our own spirits, but must be at the expence of true French brandy for it; our own spirits, though equally coloured, would never make that violet tincture, because their colour was owing to burnt sugar, not a tincture of oak. At length this mystery was explained, and a little scrapings of galls made all those quantities of this styptic, which had been set by as good for nothing, perfectly fine, and well coloured. *Shaw's Essay on Distillery.*

TEST-ACT, a statute 25 Car. II. cap. 2. which requires all officers, both civil and military, to take the oaths and test, viz. the sacrament, according to the rites and ceremonies of the Church of England; for the neglect whereof, a person executing any office, mentioned in that statute, forfeits the sum of 500 l. recoverable by action of debt.

TESTACEOUS, in natural history, an epithet given to a species of fish, which are covered with a strong thick shell, as tortoises, oysters, pearl-fish, &c.

In strictness, however, testaceous is only applied to fish whose strong and thick shells are entire and of a piece: those which are soft, thin, and consist of several pieces jointed, as the lobster, &c. being called crustaceous.

But, in medicine, all preparations of shells and substances of the like kind, are called testaceous powders: such are powder of crab's claws and eyes, hartshorn, pearl, &c. Dr. Quincy and others suppose the virtue of all testaceous medicines to be alike; that they seldom or never enter into the lacteals, but that the chief of their action is in the first passages; in which case they are of great use in absorbing acidities.

Hence they become of use in fevers, and especially in rectifying the many distempers in children, which generally owe their origin to such acidities.

TESTAMENT, *Testamentum*, in law, a solemn and authentic act whereby a person declares his will, as to the disposal of his estate, effects, burial, &c.

The word is formed from the Latin *testamentum*, which the lawyers usually derive from *testatio mentis*.

TESTATOR, or **TESTATRIX**, the person who makes his or her will and testament.

TESTES, in anatomy, two white, soft, oval bodies serving for generation; usually called diminutively, testicles.

TESTES of the Brain, are two little, round, hard bodies between the third and fourth ventricle, near the pineal gland. See **BRAIN**.

TESTICLE, *Testis*, in anatomy, a double part in male animals, serving for generation. See the article **GENERATION**.

The testicles are two in number, of an oval or egg-like figure, and are contained in a peculiar bag, called the scrotum.

But besides this external covering, the testicles themselves have their coats or tunics; the first of which composes the cremaster-muscle, the office of which is to raise the testicle; the second is the vaginalis tunica, formed of a process of the peritonæum, and laxly surrounds the testicle; the third is the tunica albuginea, which is robust and strong, and adheres closely to the substance of the testicle: this last receives the spermatic vessels, and conveys them to the testicle.

The substance of the testicles is vasculous, being composed of a great number of extremely minute vessels, called *vascula seminalia*; which are convoluted together in the manner of the intestines, and appear beautifully after macerating the testicles in vinegar. There is also a body, called, from the discoverer, *corpus Highmori*, wherein there is a cavity for the reception of the semen: this, in human subjects, is placed in the back of the testicle; but in dogs, and many other animals, it is in the middle of the testicle.

The vessels of the testicles are otherwise called spermatics. As to the use of the testicles, it is to produce the semen masculinum, for the purpose of generation.

Some also give the name of female testicles, testes muliebres, to the ovaries of women.

Tumours of the TESTICLES. When these happen from any external injury, the best applications to disperse them, says Heister, are vinegar of litharge, lime-water, spirit of wine camphorated, and ceruse, tutty, or lapis calaminaris mixed in it; but in the night-time, when the applications of fomentations are not so convenient, a plaster of the mercurial kind, doubly sated with mercury; or, in slight cases, one of simple diachylon, may very properly be kept on. Internal medicines, such as nitre, and the thin decoctions of discutient medicines, are also to be used; and, if occasion call for it, bleeding in the arm is very proper.

This may be the method with tumours of these parts, from external injuries; but when they are from venereal causes, it is always necessary to give brisk purges, with the addition of a proper dose of calomel to each; and warm and weak drinks should be taken frequently, by which means these tumours are often dispersed.

But if either remedies are applied too late, or the inflammation is too violent, the tumour generally ends either in a suppuration or gangrene. In this case the maturing remedies are to be applied, such as warm cataplasms and the like; and if the tumour does not break of itself at a proper time, from the application of these, it must be carefully opened with the knife, and the matter being discharged, the wound is to be cleansed by injecting vulnerary decoctions, and afterwards healed with balsam of Peru, or the like.

TESTICULATED, among botanists, an appellation given to roots composed of two tuberosé knobs, resembling testicles: such are those of orchis, &c.

TESTIMONIAL, a kind of certificate, signed either by the master and a fellow of the college where the person last resided; or by three, at least, reverend divines, who knew him well for three years last past, giving an account of the virtues, uniformity, and learning of the person.

Testimonial is also a certificate, under the hand of a justice of peace, testifying the place and time when a soldier or mariner landed, and the place of his dwelling, &c. whither he is to pass.

There is also another kind of testimonial for the clergy, made by persons present, that a clergyman has in all things complied with the act of uniformity; and to certify, that the clerk has performed what the law requires on his institution and induction.

TESTIMONY, the same with evidence.

TESTUDO, in zoology, a genus of amphibious animals, with four legs and a tail, and the body covered with a firm shell.

This genus comprehends all those animals known in English by the names of tortoises and turtles; of which there are a great many species, some with four toes on each foot, others with five toes on the fore feet, and four on the hinder ones; and others, distinguished by other peculiarities, particularly the compartments of their shells, some being divided into irregular spaces, and others beautifully tessellated.

The shells of these animals are much used in ornamental works, under the name of tortoise shells.

The turtle, whose flesh is so finely flavoured, and so much esteemed at table, is caught in great abundance in the American seas; and grows to a vast size, some having been found to weigh 480 pounds.

The Americans find so good account in catching turtle, that they have made themselves very expert at it: they watch them from their nests on shore, in moonlight nights; and, before they reach the sea, turn them on their backs, and leave them till morning; when they are sure to find them, since they are utterly unable to recover their former posture: at other times they hunt them in boats, with a peculiar kind of spear, striking them with it through the shell; and as there is a cord fastened to the spear, they are taken much in the same manner as the whales.

TESTUDO, in antiquity, was particularly used among the poets, &c. for the ancient lyre; by reason it was originally made by its inventor, Mercury, of the black

or hollow shell of the *testudo aquatica*, or sea-tortoise, which he accidentally found on the banks of the river Nile.

TESTUDO, in the military art of the ancients, was a kind of cover or screen which the soldiers, e. gr. a whole company, made themselves of their bucklers, by holding them up over their heads, and standing close to each other. This expedient served to shelter them from darts, stones, &c. thrown upon them, especially those thrown from above, when they went to the assault.

TESTUDO was also a kind of large wooden tower which moved on several wheels, and was covered with bullocks-hides flayed, serving to shelter the soldiers when they approached the walls to mine them, or to batter them with rams.

It was called *testudo*, from the strength of its roof, which covered the workmen as the shell does the tortoise.

TESTUDO veliformis quadrabilis, a hemispherical vault, or ceiling of a church, wherein four windows are so contrived, as that the rest of the vault is quadrable, or may be squared.

The determining of those windows was a problem proposed to the great mathematicians in Europe, particularly the cultivators of the new calculus differentialis in the *Acta Eruditorum Lipsiæ*, by Sig. Niviani, under the fictitious name of A. D. pio lisci pusillo geometra, which was the anagram of *postremo Galilæi discipulo*.

It was solved by several persons, particularly Mr. Leibnitz, the very day he saw it: and he gave it in the *Leipscic Acts* in an infinity of manners; as also did M. Bernouilli, the marquis de l'Hospital, Dr. Wallis, and Dr. Gregory.

TETANUS, in medicine, is a convulsive motion that makes any part rigid and inflexible. See **CONVULSION**.

TETRACHORD, in the ancient music, a concord consisting of three degrees, tones, or intervals, or four sounds, or terms; called also by the ancients *τετραχορδον*, and by the moderns a fourth.

This interval had the name tetrachord given it, with respect to the lyre and its chords or strings.

TETRADECARHOMBIS, in natural history, the name of a genus of fossils, of the class of the selenitæ, expressing a rhomboidal body, consisting of fourteen planes.

The characters of this genus are, that the bodies of it are exactly of the same form with the common selenitæ; but that in these each of the end-planes is divided into two, and there are, by this means, eight of these planes instead of four. Of this genus there are only three known species. 1. A thin, pellucid one, with transverse filaments, which is frequent in the clay pits of Northamptonshire, and some other counties. 2. A dull, thicker kind, with very slender, transverse filaments: this is a very rare species, and found, as far as is yet known, only in Leicestershire in the yellow brick clay, and at small depths. And, 3. A large scaly kind, considerably long, and of a very rough surface: this is found in Yorkshire, and that sometimes loose, on the sides of the hills, but more frequently buried in the strata of clay.

TETRADIAPASON, a musical chord, otherwise called a quadruple diapason, or eighth.

TETRADITÆ, a name given to several different sects of heretics. The Sabbathians were called *tetraditæ*, from their keeping Easter-day on the fourth day, or on Wednesday. The Manichees, and others who admitted of a quaternity instead of a trinity in the Godhead, were also called *tetraditæ*. The followers of Petrus Fulensis had the same appellation, by reason of the addition they made to the trisagion, to support an error they held, that in our Saviour's passion it was not any particular person of the Godhead that suffered, but the whole deity.

TETRADYNAMIA, in botany, a class of plants, whose flowers have four of their stamina of more efficacy than the rest: these are always known by having the four efficacious stamina longer than the rest.

The *tetradynamia* of Linnæus include those called by

T E T

Tournefort cruciformes, and by Ray, filiquosæ, and filiculosæ.

The general characters of which are these: the perianthium is of an oblong figure, and is composed of four leaves, which are oval, oblong, hollow, obtuse, and converging toward one another, and are gibbous at the base: these all fall off with the flower, and stand in pairs; the opposite ones being always equal in length, this cup is properly the nectarium of the plant, and it is on this occasion that it is gibbous at the base. The flower is of that kind called by Tournefort, cruciform; it consists of four equal petals, which have unguis of the length of the cup, erect, and flat; the petals are broad at the top, and obtuse, and scarce touch one another at the sides; and the insertion of the petals and of the stamina is in the same place.

The stamina are six subulated erect filaments, the two opposite ones are of the length of the cup, the other four are something longer, and are of a less length however than the petals. The antheræ are oblong and pointed, thick at the base and erect, with apices bending sideways. The nectariferous gland in the different genera of this class, is differently situated. It usually, however, is found near the stamina, and most frequently of all is affixed to some short filaments, and stands near their base. Two of the stamina are often curved, that they may not press upon this gland; and it is often owing to this, that two are shorter than the rest. The germen of the pistil is placed above the receptacle, and is every day in its growth raised higher and higher. The style is sometimes wanting, but in such plants as have it, it is of the length of the longer stamina. The stigma is always obtuse.

The fruit or capsule is always a bivalve pod, which often contains two cells; this, when ripe, opens by splitting from the apex to the base, and it has always a little membranous substance serving within as a septum, when the pod is bilocular; this stands out beyond the apex, and is the rudiments of what was before the style. The seeds are roundish, and the pod usually narrow and oblong.

This is a very natural class of plants, and has been received as such under whatever name by all the systematical writers in botany: and the plants contained under it are generally supposed to be all antiscorbutics.

It is naturally subdivided into two series; the one containing the filiculose plants, and the other the filiquose: the first have a short pod, the others a long and slender one: the first pods usually have more of the remains of the style than the others.

TETRAEDRON, or **TETRAHEDRON**, in geometry, one of the five regular or platonic bodies or solids, comprehended under four equilateral and equal triangles.

It is demonstrated by mathematicians, that the square of the side of a tetraedron is to the square of the diameter of a sphere, wherein it may be inscribed, in a subsequential ratio: whence it follows, that the side of a tetraedron is to the diameter of a sphere it is inscribed in, as $\sqrt{2}$ to the $\sqrt{3}$, consequently they are incommensurable.

TETRAGON, in geometry, a general name for any four-sided figure, as a square, parallelogram, rhombus, or trapezium.

TETRAGON, in astrology, an aspect of two planets with regard to the earth, more usually called quartile.

TETRAGONIAS, a name given to a meteor, whose head is of a quadrangular figure, and its tail or train long, thick, and uniform.

TETRAGONISM, in geometry, a term used by some for the quadrature of a circle.

TETRAGONUS, in anatomy, a muscle otherwise called quadratus genæ.

TETRAGRAMMATON, a denomination given by the Greeks to the Hebrew name of God, יהוה, Jehovah, because consisting of four letters.

TETRAMETER, in ancient poetry, an iambic verse, consisting of four measures, or eight feet. This kind of verse is only found in the comic poets, as Terence, &c.

T E U

TETRANDRIA, in the Linnæan system of botany, a class of plants, the fourth in order: comprehending all such plants as have hermaphrodite flowers, with four stamina, or male parts in each. See **BOTANY**.

TETRAPETALOUS, in botany, an epithet given to flowers that consist of four single petala or leaves, placed around the pistil.

TETRAPLA, in church history, an edition of the Old Testament, published by Origen, and so called, because it contained the four different Greek versions, namely, the Septuagint, and those of Aquila, Symmachus, and Theodotion. They were placed in distinct columns, over against each other, in the same page: whence this book was called the tetrapla, or four-fold edition.

Origen bestowed infinite labour on this work, which was finished about the year 250. The original copy was deposited in the library of the church of Cæsarea in Palestine, where St. Jerom many years after, consulted, and transcribed it. The use and excellency of it being known, many copies of it were taken, and dispersed to other churches. At length, about the seventh century, the inundations of the Saracens upon the eastern parts having destroyed all libraries, wherever they came, it was after this never more heard of. However, this design of Origen's gave birth to Polyglots in after ages.

TETRAPTERA, in the history of insects, a name given to that order of insects, which have four wings.

The insects of this order are very numerous, and have certain evident distinctions in the structure of their wings, and are thence arranged under five classes; viz. the coleoptera, scleroptera, neuroptera, lipidoptera, and hyrnenoptera.

TETRAPTOTE, *tetraptoton*, in grammar, a name given to such defective nouns as have only four cases; such are *viscis*, *pecudis*, *fodis*, &c. as being deprived of the nominative and vocative singular.

TETRAPYRAMIDIA, in natural history, the name of a genus of spars, influenced in their shape by an admixture of particles of tin, and found in form of broad-bottomed pyramids of four sides.

Of this genus there is only one known species, which is usually of a brownish colour, and found in Saxony, as also in Devonshire, Cornwall, and other counties of England, where there is tin.

TETRARCH, *Tetrarcha*, a prince who holds and governs a fourth part of a kingdom. Such originally was the import of the title tetrarch; but it was afterwards applied to any petty king or sovereign, and became synonymous with ethnarch.

TETRASTICH, a stanza, epigram, or poem, consisting of four verses.

TETRASTYLE, in the ancient architecture, a building, and particularly a temple, with four columns in its front.

TETRASYLLABICAL, a word consisting of four syllables.

TETRATONON, in music, a name whereby the superfluous fifth is sometimes called, as containing four tones.

TEUCRIUM, in botany, a genus of plants, the corolla of which is ringent, and formed of a single petal: the tube is cylindric and short, and terminates in an incurvated opening: the lower lip is divided into three segments; the lateral ones are of the figure of the upper lip, and somewhat erect; the middle one is much larger and rounded: there is no pericarpium; the seeds are four, roundish, and lodged in the base of the cup.

This genus comprehends the germander, polium, scordium, &c. This plant has the credit of being a great sudorific and alexipharmic. It is prescribed in malignant and pestilential fevers, and in the plague itself, as also in obstructions of the liver and spleen; it is said to destroy worms externally; it cleanses ulcers, and is applied by way of cataplasm to mitigate pain; it is at present chiefly used in the shops as an ingredient in the confectio Fracastorii.

TEUTONIC, something belonging to the Teutons, an ancient people of Germany, inhabiting chiefly along the

the coasts of the German ocean; thus, the Teutonic language is the ancient language of Germany, which is ranked among the mother tongues. The Teutonic is now called the German or Dutch, and is distinguished into upper and lower. The upper has two notable dialects, viz. 1. The Scandian, Danish, or perhaps Gothic; to which belong the languages spoken in Denmark, Norway, Sweden, and Iceland. 2. The Saxon, to which belong the several languages of the English, Scots, Frisian, and those on the north of the Elbe. To the lower the Low Dutch, Flemish, &c. spoken through the Netherlands, &c.

TEUTONIC ORDER, a military order of knights, established towards the close of the twelfth century, and thus called as consisting chiefly of Germans or Teutons.

The origin, &c. of the Teutonic order is said to be this. The Christians under Guy of Lusignan, laying siege to Acre, or Acon, a city of Syria, on the borders of the Holy Land, some Germans of Bremen and Lubec, touched with compassion for the sick and wounded of the army, who wanted common necessities, set on foot a kind of hospital under a tent, which they made of a ship's sail, and here betook themselves to a charitable attendance on them. This started a thought of establishing a third military order, in imitation of the Templars and Hospitallers. The design was approved of by the patriarch of Jerusalem, the archbishop of the neighbouring places, the king of Jerusalem, the masters of the temple and hospital, and the German lords and prelates then in the Holy Land, and pope Calixtus III. confirmed it by his bull; and the new order was called the order of Teutonic Knights of the house of St. Mary at Jerusalem. The pope granted them all the privileges of the Templars and Hospitallers of St. John, excepting that they were to be subject to the patriarchs and other prelates, and that they should pay tythe of what they possessed.

Others relate, that the Teutonic order was established at Jerusalem, before the city of Acre was besieged.

The officers of the Teutonic order, while in its splendor, were the grand master, who resided at Marienburg; under him were the grand commander; the grand marshal, who had his residence at Königsberg; the grand hospitaller, who resided at Elbing; the draper, who took care to furnish the habits; the treasurer, who lived at the court of the grand master; and several commanders, as those of Thorne, Culme, Brandenburg, Königsberg, Elbing, &c. They had also their commanders of particular castles and fortresses, advocates, proveditors, intendants of mills, provisions, &c.

This order is now little more than the shadow of what it formerly was, having only three or four commanderies, scarce sufficient for the ordinary subsistence of the grand master and his knights.

TEXT, a relative term, contradistinguished to gloss or commentary, and signifying an original discourse exclusive of any note or interpretation. This word is particularly used for a certain passage of scripture, chosen by a preacher to be the subject of his sermon.

A text-book, in several universities, is a classic author written very wide by the students, to give room for an interpretation dictated by the master or regent to be inserted in the interlines.

The Spaniards give the name of text to a kind of little poem or set of verses placed at the head of a gloss, and making the subject thereof, each verse being explained one after another in the course of the gloss.

Anciently the lawyers began all their pleadings with like texts of scripture.

TEXTURE, *Textura*, properly denotes the arrangement and cohesion of several slender bodies or threads interwoven or entangled among each other, as in the webs of spiders, or in cloths, stuffs, &c.

Texture is also used in speaking of any union or constituent particles of a concrete body, whether by weaving, hooking, knitting, tying, chaining, indenting, intruding, compressing, attracting, or any other way. In which sense we say a close compact texture, a lax porous texture, a regular or irregular texture, &c. A great deal

depends on the texture of the component parts of a body; hence most of its particular properties, its specific gravity, colour, &c.

THALAMI Nervorum Opticorum, in anatomy, two oblong prominences of the lateral ventricles of the brain, medullary without, but a little cineritious within, being thus called because the optic nerves rise out of them.

THANE, or **THAIN**, *Thanus*, a name of an ancient dignity among the English and Scots, or Anglo-Saxons. Skene makes thane to be a dignity equal to the son of an earl. Camden will have it, that thanes were only dignified by the offices they bore. There were two kinds or orders of thanes, the king's thanes, and the ordinary thanes: the first were those who attended the king in his courts, and who held lands immediately of the king. The ordinary thanes, or the *Thaniminores*, were the lords of the manors, who had particular jurisdiction within their limits, and over their own tenants; these changed their names for that of barons, and hence their courts are called courts-baron to this day.

THANE-LANDS, were lands granted by charters of our ancient kings to their thanes, with all immunities, except the threefold necessity of expedition, repair of castles, and mending bridges.

THAPSIA, Deadly Carrot, in botany, a genus of plants, the general corolla of which is uniform: the single flowers consist each of five crooked, lanceolated petals: the fruit is naked, oblong, surrounded longitudinally with a membrane, and separable into two parts: the seeds are two, large, oblong, and convex, pointed at each end, and having on each side a plane margin, large and undivided, which is emarginated at top and bottom.

This plant is used to provoke the menses, and other evacuations, and externally it is used in ointments for the itch, and the like cutaneous disorders.

THAUMATURGUS, a worker of miracles, an appellation which the Romanists give to several of their saints eminent for the number and greatness of their miracles.

THAWING, the resolution of ice into its former fluid state, by the warmth of the air, &c.

Boerhaave observes, that if a sudden thaw takes place after a long sharp frost, which has bound up the rivers, and penetrated the earth's surface to a considerable depth, it is, usually, quickly succeeded by a multitude of clouds and uncommon heats, and then by thunder and lightning. The reason is, that the fat vapours and exhalations raised by the subterraneous heat, have long remained imprisoned under that covering of the earth; as appears hence, that if the ice of a ditch be broke in the middle of a severe frost, it presently emits warm vapours, and this the more plentifully, as well as the hotter, by how much the frost is harder and the ice thicker. As soon, therefore, as the exterior frozen turf of earth is softened by warmth, the pent-up vapours immediately escape through all the passages they can find, and mounting on high, form clouds, which being driven about, and sometimes illumined by the sun, produce such effects. Hence the violent thunders in Muscovy, Sweden, and Denmark, after a thaw.

THEATINES, an order of nuns, under the direction of the Theatins.

There are two kinds of Theatines, under the title of Sisters of the Immaculate Conception, who form two different congregations, the one engaged by solemn vows, and the other only by simple vows. Their common foundress was Ursula Benincasa. Those who make the simple vows are the most ancient, and are called absolutely Theatines of the congregation: they had their rise at Naples, in 1583.

The others are called Theatines of the hermitage: the whole business of these is praying in retirement, and an austere solitude, to which they engage themselves by solemn vows.

The Theatines of the first congregation take care of the temporal concerns of these last. Their houses stand together, and communicate by a large hall. Their foundress drew up their constitutions, and laid the foundation of their house at Naples, but died before it was finished.

Gregory

T H E

Gregory the XVth, who confirmed the new institute under the rule of St. Augustin, appointed that they should be under the direction of the Theatins. Urban VIII. revoked this article by a brief in 1624, and subjected them to the nuncio of Naples: but Clement IX. annulled this brief, and submitted them anew to the Theatins by a brief in 1668.

THEATINS, a religious order of regular priests, thus called from their first superior Don John Pietro Caraffa, archbishop of Chieff, in the kingdom of Naples, which was anciently called Theate.

The same archbishop was afterwards pope, by the name of Paul IV. after having been a companion of Gaëtan, a Venetian gentleman, the first founder of this order, at Rome, in 1524.

The Theatins were the first who assumed the title of regular clerks. They have not only no lands, or fixed revenues, either in common or in propriety; but they do not even ask or beg any thing; but wait for what Providence shall send them for their subsistence.

They employed themselves much in foreign missions; and in 1627 entered upon Mingrelia, where they have an establishment: they have had the like in Tartary, Circassia, and Georgia, which they have since abandoned, by reason of the little fruit they perceived thereof.

Their first congregation appeared at Rome in 1524, and was confirmed the same year by Clement VII.—Their constitutions were drawn up at a general chapter in 1604, and approved by Clement VIII. They wear the priests habit.

THEATRE, *θεατρον*, in antiquity, a public edifice for the exhibiting of scenic spectacles, or shews, to the people; comprehending not only the eminence on which the actors appeared, and the action passed, but also the whole area of the place, common to the actors and spectators.

The Romans borrowed the form of their theatres from those of the Greeks, which were generally built in the shape of a semi-circle, encompassed with porticos, and furnished with seats of stone, disposed in semi-circles, rising gradually one above another.

The principal parts of the antient theatres were the *scena*, *proscenium*, *orchestra*, and *area*.

Among the moderns, theatre more peculiarly denotes the stage, or place whereon the drama or play is exhibited; answering to the *proscenium* of the antients. It is also used, in a more comprehensive sense, for the whole play-house.

THEATRE is also used in architecture, chiefly among the Italians, for an assemblage of several buildings, which, by a happy disposition and elevation, represents an agreeable scene to the eye.

Anatomical THEATRE, in a school of medicine and chirurgery, is a hall, with several rows of seats, disposed in the circumference of an amphitheatre; having a table bearing on a pivot, in the middle, for the dissection of bodies.

THEBAID, *Thebais*, a celebrated heroic poem of Statius, the subject whereof is the civil war of Thebes, between the two brothers Eteocles and Polynices; or, Thebes taken by Theseus.

The Thebaid is censured by the best of critics, for a multiplicity of fables and actions; for too much heat and extravagance, and for going beyond the bounds of probability.

THEFT, *furtum*, in law, an unlawful felonious taking away another man's moveable and personal goods, against the owner's will, with intent to steal them.

It is divided into theft or larceny, properly so called, and petit theft, or petit larceny; the former of which is of goods above the value of twelve-pence, and is deemed felony: the other, which is of goods under that value, is not felony.

THEFTBOTE, the receiving a man's goods again from a thief or other amends, by way of composition, and to prevent prosecutions, that the felon may escape unpunished; the punishment of which is imprisonment, but not the loss of life or members.

THELONIUM, in law-books, is used to denote any kind of toll: hence, citizens and other persons who

T H E

have a right to be free from toll, may have a writ called *breve essendi quieti de thelonio*.

THEME, in matters of education, denotes the subject of an exercise, for young students to write or compose on.

THEME, among astrologers, denotes the figure representing the state of the heavens for any time required; that is, the places of the stars and planets for that time.

THENAR, in anatomy, the abductor-muscle of the thumb: it has its origin in the transverse ligament that joins the bones of the carpus, and its termination in the first and second phalanx: the two sesamoid bones of the thumb are usually found lodged in the tendon of this muscle.

The abductor-muscle of the great toe, likewise called *thenar*, has its origin from the internal side of the calcaneum, and the *os naviculare*; and its termination at the internal side of the great toe, beside the internal sesamoid bone.

THEOBROMA, in botany, a genus of plants; the empalement of the flower is composed of three oval concave leaves, which are reflexed. The flower has five oval petals, which spread open, and are hollowed like a spoon; from the top of each petal comes out a bifid bristly ligula, divided like two horns. It has a great number of short stamina joined in five bodies, which are terminated by roundish summits, and a roundish germen supporting a single style the length of the petals, crowned by a single stigma. The germen afterward turns to a roundish fruit with five angles, opening in five cells, each containing several seeds.

This tree grows naturally in most of the islands in the West Indies, where it rises to the height of forty or fifty feet, having a trunk as large as a middle-sized man's body, covered with a dark brown furrowed bark, sending out many branches toward the top, which spread wide on every hand, garnished with oblong heart-shaped leaves, placed alternate, of a bright green on their upper side, and pale on their under, sawed on their edges, with a strong midrib, and several transverse veins, standing upon short foot-stalks. The flowers come out in bunches from the wings of the leaves; they are small, of a yellow colour, having five concave petals, which spread open circularly, and a great number of stamina, which at their base are joined in five bodies, terminated by roundish summits. In the center is situated a roundish germen, supporting a slender style the length of the stamina, crowned by a single stigma. The germen afterward turns to a roundish warted fruit, having five obtuse angles, and five cells, which contain several irregular seeds.

The wood of this tree is white and ductile, so is frequently cut into staves for casks. The fruit and leaves are good fodder for cattle, therefore when the planters clear the land from wood, they leave the trees of this standing for the seed, which is of great use in dry seasons, when the common fodder is scarce.

There are some plants of this sort in England preserved in the gardens of curious persons; it is propagated by seeds, which must be procured as fresh as possible, from the countries where the plants grow naturally. These should be sown upon a good hot bed in the spring; and, when the plants are fit to remove, they should be each planted in a separate small pot, and plunged into a hot bed of tanners bark, observing to shade them from the sun till they have taken new root; then they should be treated in the same way as the coffee-tree, keeping them always in the tan-bed in the stove.

THEOCRACY, *θεοκρατεια*, in matters of government, a state governed by the immediate direction of God alone; such was the antient government of the Jews, before the time of Saul.

THEODOLITE, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

It is made variously, several persons having their several ways of contriving it, each more simple and portable, more accurate and expeditious than others. The common one consists of a brass-circle about a foot diameter,

meter, cut in the form represented in plate CXXVII. *fig. 1.* having its limb divided into 360 degrees, and each degree subdivided, either diagonally, or otherwise, into minutes.

Underneath, at *cc*, are fixed two little pillars *bb*, *fig. 2.* which support an axis, whereupon is fixed a telescope consisting of two glasses, in a square brass tube, for the viewing of remote objects.

On the center of the circle moves the index *C*, which is a circular plate, having a compass in the middle whose meridian line answers to the fiducial line *aa*: at *bb*, are fixed two pillars to support an axis which bears a telescope like the former, whose line of collimation answers to the fiducial line *aa*. At each end of either telescope, is fixed a plain sight for the viewing nearer objects.

The ends of the index *aa* are cut circularly, to fit the divisions of the limb *B*; and when that limb is diagonally divided, the fiducial line, at one end of the index, shews the degrees and minutes upon the limb. The whole instrument is mounted with a ball and socket, upon a three-legged staff.

Most theodolites have no telescopes, but only four plain sights, two of them fastened on the limb, and two on the ends of the index.

Mr. Sisson's improved theodolite being one of the best of these instruments, we shall here give its description, *fig. 3.* The three staves, whereby it is supported, screw into bell-metal joints by brass ferrils at top, which are moveable between brass pillars fixed in a strong brass plate; in which, round the center, is fixed a socket with a ball moveable in it, and upon which the four screws press that set the limb horizontal. Next above is such another plate, through which the said screws pass, and on which round the center is fixed a frustum of a cone of bell-metal, whose axis, being connected with the center of the ball, is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass-box, and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes, in whose plate are fixed four brass pillars, that joining at top, hold the center-pin of the bell-metal double sextant, whose double index is fixed in the center of the same plate. Within the double sextant is fixed the spirit-level, and over it the telescope.

The compass-box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

The limb has two fleur-de-luces against the diamonds in the box, and is curiously divided into whole degrees, and numbered to the left hand at every 10° to twice 180°, having three indexes, with Nonius's divisions on each for the decimals of a degree, that are moved by a pinion fixed below one of them without moving the limb, and in another is a screw and spring under, to fix it to any part of the limb: it has also divisions numbered for taking the quarter girt in round timber; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

The double sextant is divided on one side from under its center, when the spirit-tube and telescope are level, to above 60 degrees each way, and numbered at 10, 20, &c. And the double index, through which it is moveable, shews on the same side the degree and decimal of any altitude, or depression to that extent, by Nonius's divisions; on the other side are divisions numbered for taking the upright height of timber, &c. in feet, when distant ten feet, which at 20 must be doubled, and at 30 trebled; and also the quantities for reducing hypotenusal lines to horizontal: it is moveable by a pinion fixed in the double index.

The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distinct object as perfect, as most of treble its length: in its focus are very fine cross wires, whose intersection is in the plane of the double sextant, and this is a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that whenever the limb is set horizontal, which is readily done by making the spirit-tube level over two

screws, and the like over the other two, the double sextant and telescope are moveable in a vertical plane, and then every angle taken on the limb, though the telescope be never so much elevated or depressed, will be an angle in the plane of the horizon; and this is absolutely necessary in plotting an horizontal plane.

The use of the theodolite is abundantly shewn in that of the graphometer, or semi-circle, which is only half a theodolite; and in that of the plain table, which is occasionally made to be used as a theodolite. Note, the index and compass of a theodolite, likewise serve for a circumferentor, and are used as such.

THEOGONY, that branch of the heathen theology, which taught the genealogy of their gods.

THEOLOGIUM, in the ancient theatre, a kind of little stage, above that whereon the ordinary actors appeared; being the place where the machinery of the gods were disposed; whence the name.

THEOLOGY, or **DIVINITY**, a science which instructs us in the knowledge of God, or divine things; or which has God, and the things he has revealed, for its object.

Hence theology may be distinguished into natural, which comprehends the knowledge we have of God from his works, by the light of reason alone; and supernatural, which contains what we are taught concerning God in revelation.

Theology is again distinguished into positive, moral, and scholastic. Positive knowledge is the knowledge of the Holy Scriptures, and of the signification thereof, conformably to the opinions of the fathers and councils, without the assistance of any argumentation. Some will have it, that this ought to be called expositive rather than positive. Moral theology, is that which teaches us the divine laws relating to our manners and actions. Scholastic, or school theology, is that which proceeds by reasoning; or that derives the knowledge of several divine things from certain established principles of faith.

THEORBA, **THIORBA**, or **TIORBA**, a musical instrument made in form of a large lute, except that it has two necks or juga, the second and longer of which sustains the four last rows of chords which are to give the deepest sounds.

THEOREM, a speculative proposition, demonstrating the properties of any subject. Theorems are either universal, which extend to any quantity, without restriction universally; as this, that the rectangle of the sum and difference of any two quantities, is equal to the difference of their squares: or particular, which extend only to a particular quantity; as this, in an equilateral right-lined triangle, each of the angles is 60 degrees.

Theorems are again distinguished into negative, local, plane, and solid.

A negative theorem is that which expresses the impossibility of any assertion; as that the sum of two biquadrate numbers cannot make a square number. A local theorem is that which relates to a surface; as, that the triangles of the same base and altitude are equal. A plane theorem is that which either relates to a rectilinear surface, or to one terminated by the circumference of a circle; as that all angles in the same segment of a circle are equal. And a solid theorem is that which considers a space terminated by a solid line; that is, by any of the three conic sections, e. gr. this: that if a right line cut two asymptotic parabolas, its two parts terminated by them shall be equal.

Reciprocal THEOREM, is one whose converse is true; as that, if a triangle have two equal sides, it must have two equal angles; the converse of which is likewise true, that, if it have two equal angles, it must have two equal sides.

THEORETIC, or **THEORETICAL**, something relating to theory, or that terminates in speculation.

Hence theoretical astronomy is that part of astronomy, which accounts for the various phenomena of the stars and planets.

THEORY, in general, denotes any doctrine which terminates in speculation alone, without considering the practical uses and application thereof. Thus the theory of chemistry, for instance, contains all the general truths

which the particular experiments of chemists have hitherto demonstrated. These are, on this occasion, to be taken for granted, and the whole body of such truths makes the universal theory of chymistry, for chymistry is no science formed *a priori*; it is no production of the human mind, or raised by reasoning, but collected *a posteriori* from experiments: it took its rise from various operations, casually made, and observing those that had one and the same uniform tendency, without any expectation of what followed; and was only reduced into an art, by collecting and comparing the effects of such uncertain experiments, and noting the tendency thereof: so far then as a number of experiments agree to establish any unquestionable truth; so far they may be considered as constituting the theory of chymistry.

Such a theory is necessary to be premised to every art; and something equivalent to this is practised by every artisan, in teaching his disciple how to proceed orderly in the exercise of his art; and accordingly it would be impossible to teach the practice of chymistry to advantage, without having first given some such theory. Thus it would be to little purpose to give a novice a parcel of rosemary, for instance, and bid him, without any addition, distil a water from it, which should contain the natural taste and odour of the plant; unless he knew beforehand this general truth, that plants, exposed to a gentle heat, like that of the summer's sun, do exhale their most subtile and volatile parts, which, being collected and condensed by means of proper vessels, appear in form of water, and are the thing required.

THERAPEUTÆ, a term applied to those who are wholly employed in the service of religion. This general term has been applied to particular sects of men, concerning whom there have been great disputes among the learned.

It is generally supposed that St. Mark established a particular society of Christians about Alexandria, of whom Philo gives an account, and calls them Therapeutæ. He speaks of them as a particular sect, retired from the world, who spent their time in reading the writings of ancient authors, in singing hymns and songs composed by some of their own sect, and in dancing together the whole night. Scaliger maintains, they were Essene Jews; but Valesius rejects this opinion of Scaliger, 1. Because Philo never calls them Essenes. 2. Because there were no Essenes but in the Holy Land; whereas the Therapeutæ were spread through Greece, and all the barbarous nations. 3. Because Josephus, who gives a very ample account of the Essenes, does not say one word of the Therapeutæ.

THERAPEUTICE, THERAPEUTICS, that part of medicine which acquaints us with the rules that are to be observed, and the medicines to be employed in the cure of diseases.

THERAPHIM, or TERAPHIM, certain images, or superstitious figures mentioned in scripture.

We meet with this word thirteen or fourteen times in scripture, where it is commonly interpreted idols; but the rabbins are not contented to have it simply signify idols, but will have it denote a peculiar sort of idols or images for the knowledge of futurity, i. e. oracles.

R. David de Pomis observes, that they were called theraphim, from *רפא*, raphah, to leave, because people quitted every thing to consult them. — He adds, that the theraphim were in human shape; and that, when raised upright, they spoke at certain hours, and under certain constellations, by the influence of the celestial bodies. This is a rabbinical fable, which he has learned from Abenezra.

Others hold, that the theraphim were brazen instruments which pointed out the hours and minutes of future events, as directed by the stars. — De Pomis corrects Abenezra, saying, that the theraphim being made under a certain constellation, the devil made them speak under the same.

R. Eliezer tells us the reason why the rabbins will have the theraphim to speak, and render oracles: it is, says he, because it is written, in the prophet Zachary, x. 2. "The theraphim have spoken vain things."

The same rabbin adds, that, to make the theraphim,

they killed a first-born child, clove his head, and seasoned it with salt and oil; that they wrote on a plate of gold the name of some impure spirit, laid it under the tongue of the dead, placed the head against the wall, lighted lamps before it, prayed to it, and it talked with them.

Be this as it will, Vorstius observes, that, besides the passage of Zachary just quoted, it appears likewise from Ezekiel xxi. 22, that the theraphim were consulted as oracles.

De Pomis endeavours to shew, that the theraphim, which Michal put in David's bed, were not of this kind, because they were not in the figure of men: but R. Eliezer is of another sentiment.

As to the manner of making the theraphim, Vorstius takes it to be a vain tradition of the rabbins, though R. Tanchuma and Jonathan, in his Targum, Gen. xxxi. 19, relate it after R. Eliezer. — The chief reason of his disbelief is, that Laban, who had not quite lost all notion of the true God, as appears from Gen. xxxi. 53, could not be guilty of so great a cruelty: but Vorstius does not consider, that the custom might not be less real, for its not having been established so early as Laban: and that the Hebrews sometimes burnt their children to Moloch.

F. Kircher directs us to seek the origin of the theraphim in Egypt; adding, that the word is Egyptian. — Spencer, in his dissertation on the Urim and Thummim, maintains the word to be Chaldee, and to signify the same with seraphim, the Chaldeans being frequently known to change the *U* into *N*, that is, *S* into *T*. He adds, that those images were borrowed from the Amorites, Chaldeans, or Syrians; and that the Serapis of the Egyptians is the same thing with the theraphim of the Chaldeans. See *Selden de Diis Syris*, *syn. l. c. 2.*

THERIACA, ANDROMACHI, a compound medicine, made in the form of an electuary, the ingredients of which, according to the college of London physicians, are as follows: Take of the troches of squills, half a pound; long pepper, opium strained, dried vipers, of each three ounces; cinnamon, balsam of Gilead, or in its stead expressed oil of nutmeg, of each two ounces: agaric, the root of Florentine orrice, water germanander, red roses, seeds of navew, extract of liquorice, of each an ounce and a half; spikenard, saffron, amomum, myrrh, costus, or in its place zedoary, camels hay, of each an ounce; the root of cinquefoil, rhubarb, ginger, Indian leaf, or in its room mace, leaves of dittany of Crete, of hore-hound, and of calamint, French lavender, black pepper, seeds of Macedonian parsley, olibanum, Chio turpentine, root of wild valerian, of each six drams; gentian root, Celtic nard, spignel, leaves of poley-mountain, of St. John's wort, of ground pine, tops of creeping germander, with the seed, the fruit of the balsam-tree, or in its stead cubebs, aniseed, the lesser cardamom seeds husked, seeds of bishop's weed, of hartwort, of treacle mustard, or mithridate mustard, juice of the rape of cistus, acacia, or in its stead Japan earth, gum arabic, storax strained, sagapenum strained, Lemnian earth, or in its stead bole armenic or French bole, green vitriol calcined, of each half an ounce; root of creeping birthwort, or in its stead of the long birthwort, tops of the lesser centaury, seeds of the carrot of Crete, opopanax, galbanum strained, Russia castor, Jew's pitch, or in its stead, white amber prepared, root of the sweet flag, of each two drams; of clarified honey, thrice the weight of all the rest. The ingredients are to be mixed in the same manner as in the mithridate.

The college of Edinburgh have given the following reformation of this composition, under the title of Theriaca Edinensis.

Take of Virginian snake root, six ounces; wild valerian root, contrayerva root, each four ounces; aromatic powder, three ounces; resin of guaiacum, Russia castor, myrrh, each two ounces; English saffron, opium, each one ounce; clarified honey, thrice the weight of the powders; canary wine, as much as is sufficient to dissolve the opium. This composition consists of very powerful ingredients, and is doubtless capable of answering every thing that can be reasonably expected from the more voluminous theriaca of Andromachus.

The

The theriaca Andromachi is a reform of mithridate, made by Andromachus, physician to Nero; for the virtues whereof, see the article MITHRIDATE.

THERMÆ, artificial hot baths much used by the Romans.

THERMOMETER, an instrument for measuring the increase and decrease of the heat and cold of the air, by means of the elastic and expansive power of bodies of the fluid sort.

Many different ways, methods, and forms of constructing such an useful instrument have been thought of, and invented at several times for this purpose; at first air, then oil, then spirits of wine, and lastly, quicksilver, have been every way attempted and tortured in this experiment.

The spring of air, being sooner affected by heat and cold than that of any other fluid, was first thought upon as the best expedient to answer this end; and so it really would be, were it not that the weight or pressure of the atmosphere affects it also at the same time; and by acting sometimes with, sometimes against it, renders the effect by heat or cold very uncertain, and, therefore, the instrument useless. For example: the air in the bottle *AF* (plate CXXVII. fig. 4.) will, by its expansion, when the air grows warmer, raise the water higher in the tube than the point *H*, and if the air be lighter at this time, it will press less on the surface of the water at *H*, and so will suffer it to rise still higher. But if the air be heavier, it will act against the spring, and not permit it to raise the water so high. The same may be observed with respect to its contraction by cold; wherefore such an instrument, for common or constant use, will not do at all, though, perhaps, none is better calculated for some extemporaneous uses, as measuring the degree of coldness in different cellars, or of warmth in divers rooms upon the same floor.

It was upon this account found necessary to have recourse to some other fluid, which, secured from the pressure of the air in a tube, hermetically sealed, might expand and contract solely by the heat and coldness of the air about it. And, because most fluids are subject to freeze, or thicken, in great degrees of cold, it was soon considered that spirits of wine, a little tinged with cochineal, would best answer the purpose; and, accordingly, thermometers were generally made therewith, and became of common use.

Though the spirit of wine thermometers would do very well to shew the comparative heat of the air, yet this was far short of the virtuoso's views, who wanted to explore the various and vastly different degrees of heat in other bodies, as boiling water, boiling oils, melted metals, and even fire itself, and degrees of cold too, beyond what the spirit thermometer can shew. For the spirit, in a moderate degree of heat, will burst the tube; and, in an intense degree of cold, will freeze, as the French philosophers found, who went to measure a degree upon the surface of the earth under the north polar circle. It having been found by experiment, that linseed oil required four times the degree of heat to make it boil as water did, it was quickly substituted instead of spirits for philosophic uses. This Sir Isaac Newton always used, and by it discovered the comparative degree of heat which makes water boil, which melts wax, which makes spirit of wine boil, and melts tin and lead; beyond which we do not find the oil-thermometer has been applied; for which reason, as also for its sullying the tube, it has been less used of late, and given way to

The mercurial thermometer, which will sustain any degree of heat or cold, as far as any instrument of this kind can be expected to do. Mr. Fahrenheit, of Amsterdam, was the contriver of this thermometer, and though several artificers made them as well as he, yet they still go by his name. Dr. Boerhaave used only this thermometer. As the mercury very freely and uniformly expands itself from hard frost to the heat of summer, so one sort of those thermometers are contrived with a scale, to include those extremes only, and the beginning of the divisions, or 0, is fixed to the altitude of the quicksilver, as is observed when water just begins to freeze, or snow to thaw; for which reason that is called the freezing point

in the scale. This thermometer is small, short, put in a neat frame, and carried in the pocket any where.

But the grand thermometer of Fahrenheit is graduated after a different manner, as destined to a more critical and extensive use. In this the bulb, or large part at the bottom, is not spherical, as in common ones, but cylindrical, to the end, that the heat may penetrate and reach the inmost parts as soon as possible, so that the whole may expand uniformly together. Hence it is, that in the cylindric bulb the fluid will expand and rise immediately, whereas in the spherical bulb it is seen first to fall, by the sudden expansion of the ball, before the fluid is heated, and then to rise, by the expansion of the fluid when heated. We have given a figure, both of Fahrenheit's mercurial thermometer, and also of Sir Isaac Newton's made with linseed oil. See plate CXXVII. fig. 5.

Sir Isaac's seems to be the best fitted of any for a standard weather thermometer; and even for any degree of heat which the various states of the human body exhibit; and also for those different degrees which vegetation requires in the green-house, hot-bed, &c. In all which cases it is necessary there should be one common, unerring, and universal measure, or standard, which at all times, and at every place, will shew the same degree of heat, by the same expansion of the fluid, according to which the scale should be made in every standard thermometer. In order to this, the tube proposed should be very nicely weighed, when empty, and then the bulb, and about a tenth part of the length of the tube above it, is to be filled with quicksilver; then it is to be weighed again, and the excess of this, above the former weight, will give the weight of the quicksilver poured in; this will give the weight of the hundredth part. Let a mark be made with a file upon the tube at the surface of the inclosed quicksilver.

Then weigh out nine or ten parcels of quicksilver, each equal to a hundredth part of that first put in the tube, and having poured the several parcels in one after another upon the inclosed quicksilver, and marked the tube successively at the surface of each parcel, you will have the tube divided into proper intervals, which, if the bore of the tube be every-where the same, will be equal to each other; if not, they will be unequal; and each of these intervals is to be divided into ten others, increasing or decreasing as the intervals do.

When this is done, the capacity of the tube is divided into thousandth parts of that of the ball, and the contiguous part of the tube reaching up to the first mark. The tube is now to be put into a frame, and by the side of it is to be placed a scale, divided into thousandth parts, exactly corresponding to those on the tube; and writing 1000 over-against the first mark, you write 1010 over-against the second, 1020 against the third, and so on, as you see in the figure.

The standard thermometer-tube, and its scale, being thus constructed, is then to be filled with some proper fluid, as linseed oil, where great degrees of heat are not proposed; and mercury is to be used, when they are. When the fluid is poured in, it is to be adjusted in such a quantity, that it may stand just at the principal point; marked 1000, in water just freezing. And here great precaution is to be used; for many trials must determine this point to which the fluid must always rise by flow degrees, and with an uniform motion.

When this point is well secured, all the trouble is over, the ball, being then immersed in boiling water, spirits, oils, melted metals, &c. in snow, freezing mixtures, &c. the expansions, by all the various degrees of heat and cold, will be shewn by the number against the heights to which the fluid rises in the tube, in each case, these are to be wrote on the side of the scale; and, since the same degree of heat will cause the same expansion of the same fluid at all times, it is evident, if thermometers were every where constructed in this manner, the observations made by them in any part of the world, may be compared together, which cannot otherwise be done; whence this part of philosophy would receive its final perfection.

By one of those standard thermometers well made, many more might soon be constructed with any expanding

ing fluid, without the trouble of graduating their tubes by equal quantities of quicksilver. For having filled the balls, and a convenient part of the tube, with the proposed fluid, place them all together in a vessel of cold water; and while it is warming as gently as possible, when the oil in the standard thermometer shall arrive successively at the several divisions of its scale, at the same instant of time mark the new tubes at the several heights of their fluids, and form a scale for every tube, that shall correspond to those marks. Then, while the liquors subside by cooling gently, examine whether they nicely agree at the several marks. To determine the freezing point in all, they are to stand together in the water till it just begins to freeze: or, having all the other points duly, that may be deduced very exactly by the rule of proportion.

A thermometer that shall vary very sensibly by every small variation of heat and cold, as those of the atmosphere, must have a large ball in proportion to the bore of the tube; and, that the heat or cold may sooner penetrate the innermost parts of the liquor, the ball should not be spherical, but oblong, and flatted like a French flask; and the lengths of the tubes should be proportioned to the degrees of heat they are intended to discover.

Sir Isaac Newton graduated his standard thermometer on both sides, as shewn in the figure. Those on the right hand measured the heat of the oil; as those on the left measured the bulk thereof: but since the latter, as well as the former, begins from a cypher at the freezing point, and is regularly continued upwards by the common divisions 10, 20, 30, 40, &c. it will equally serve both purposes; since the degree of heat will always be proportioned to the expansion of the bulk of the fluid above or below the freezing point.

By this division therefore on the left hand, we shall express some of the principal articles of Sir Isaac Newton's scale of the various degrees of heat, as in the table below.

D. of heat.	0	Water just freezing, and snow just thawing.
	1	The heats of the air in winter.
to	4	
	4	The heats of the air in spring and autumn.
to	8	
	8	The heats of the air in summer.
to	12	
	13	The greatest summer-heat.
	26	The greatest heat of the external parts of the human body.
	31	Water just tolerable to the hand at rest.
	36½	Water hardly tolerable to the hand in motion.
	43	Melted wax just growing stiff and opaque.
	51½	Melted wax just before it bubbles or boils.
	54	Spirit of wine just begins to boil.
	72	Water begins to boil.
	75	Water boils vehemently.
	86	A mixture of $\frac{1}{10}$ of lead, $\frac{2}{3}$ of tin, and $\frac{1}{2}$ bismuth, melts.
	103	A mixture of equal parts of tin and bismuth melts.
	122	A mixture of $\frac{3}{4}$ of tin and $\frac{1}{4}$ of lead melts.
	154	The heat which melts tin.
	174	The heat which melts bismuth.
	206	The least heat which melts lead.
	290	The heat with which burning bodies shine in a dark place.
	410	The heat of a small coal-fire.
	450	The heat of a small wood-fire.

Dr. Hales considers the freezing point as one boundary to vegetation, viz. on the side of cold; and the other boundary he fixes to that degree of heat with which wax will begin to melt, because a greater degree of heat will, instead of collecting and assimilating the nutritive particles, dissipate them, even those which are most viscid and glutinous; and therefore the plant will rather fade than vegetate in such degrees of heat.

This space the doctor divided into one hundred equal parts in his thermometers: but his numbers, expressed in those of the standard thermometer, are for several particulars mentioned by the doctor as follows: For myrtle,

4½; oranges, 6½; ficoides, 7½; Indian fig, 8½; aloe, 10; cereus, 11; euphorbium, 12; pimento, 13; ananas, 14½; melon-thistle, 15½; air under the glass of a hot bed, 17; the hot bed itself, 28. If the hot bed exceed the heat of 40, or thereabouts, it will scorch the plants and kill them. The heat of milk from the cow is 28; that of urine 29; and of blood in a fever nearly 40.

As Farenheit's thermometer is come into such general use, we have here placed it by the standard thermometer, that the divisions on each may be reduced to the other's respectively by bare inspection, and the use of both be still preserved. If the reader would see all the different sorts of thermometers, or rather all the different methods of graduating them, he may be fully satisfied by consulting Dr. George Martin's treatise on this subject.

The following account of the use of thermometers among gardeners, in the management of stoves, &c. is taken from Mr. Miller's *Gard. Dict.*

These instruments shew, by inspection, the present condition of the air, whether it be hot or cold; which day in summer is the hottest, and in the winter which is the coldest, or any part of the day; and from thence many useful experiments have and may be made, viz. how much one spring exceeds another in coldness; which baths are the hottest or coldest; and, if being held in the hand of a person in a fever, or otherwise applied, will nicely shew the abatement or increase of a fever.

The common thermometer, which is used for hot houses, has a tube of about two feet in length, and about the eighth part of an inch diameter; and in this it is remarked, that the air is cold for the plants when the spirit rises to fifteen inches above frost; that it is temperate at sixteen inches and a half; that it is warm when it rises to eighteen inches, which is the standard for pineapple heat. It is marked for hot air at twenty inches, and sultry hot at twenty-one and a half; but in the common thermometers, these degrees are differently marked: this temperate air is about our warm, this warm air our hot, and our hot air is about the same as the sultry.

These thermometers are marked with the names of some of the remarkable plants which are preserved in the hot houses; but as the number of these plants has been greatly increased in England of late years, I have directed some thermometers to be made with a scale, divided into degrees, and with three different points of heat marked in classes, which correspond with these thermometers; and under each class, I have drawn up lists of the several plants, ranged according to the degrees of heat in which they are found to succeed, whereby the culture of them is made easy to persons of small skill. By this means every gardener may know when it is proper to apply his heat in its full force, and what degree of heat ought to be used for the welfare of any plant from any part of the world.

Mr. Boyle, by placing a thermometer in a cave, which was cut straight into the bottom of a cliff, fronting the sea, to the depth of 130 feet, found the spirit stood, both in winter and summer, at a small division above temperate; the cave had 80 feet depth of earth above it.

I, says, Dr. Hales, marked six thermometers numerically, 1, 2, 3, 4, 5, 6. The thermometer, number 1, which was the shortest, I placed with a south aspect in the open air; the ball of number 2, I set two inches under ground; that of number 3, four inches; number 4, eight inches; number 5, sixteen inches; and number 6, twenty-four inches: and, that the heat of the earth at those several depths may the more accurately be known, it is proper to place near each thermometer a glass tube, sealed at both ends, of the same length with the stems or the several thermometers, and with tinged spirit of wine in them to the same height as in each corresponding thermometer; the scale of degrees of each thermometer being marked on a sliding ruler, with an index to the back of it pointing to the corresponding tube.

When at any time an observation is to be made, by moving the index to point to the top of the spirit in that tube

tube, an accurate allowance is hereby made for very different degrees of heat and cold in the stems of the thermometers at all depths; by which means the scale of degrees will shew truly the degrees of heat in the balls of the thermometers, and consequently the respective heats of the earth at the several depths where they are placed.

The stems of these thermometers, which were above the ground, were fenced from weather and injuries, by square wooden tubes. The ground they were placed in was a brick earth in the middle of my garden.

July the thirtieth I began to keep a register of their rise and fall: during the following month of August I observed, that when the spirit in the thermometer, number 1, which was exposed to the sun, was about noon, risen to 48 degrees, then the second thermometer was 45, the fifth 33, and the sixth 31; the third and fourth at intermediate degrees; the fifth and sixth thermometers kept nearly the same degree of heat, both night and day, till towards the latter end of the month, when, as the days grew shorter and cooler, and the nights longer and cooler, they then fell to 25 and 27 degrees.

Now so considerable a heat as the sun, at two feet depth under the earth's surface, must needs have a strong influence in raising the moisture at that and greater depths, whereby a very great and continual reek must always be ascending during the warm summer season, by night as well as by day; for the heat at two feet depth is nearly the same night and day, the impulse of the sunbeams giving the moisture of the earth a brisk undulating motion; which watery particles, when separated and rarefied by heat, ascend in the form of a vapour; and the vigour of the warm and confined vapour, such as is that which is one, two, or three feet deep in the earth, must be very considerable, so as to penetrate the roots with some vigour, as we may reasonably suppose from the vast force of confined vapour in æolipiles, in the digester of bones, and the engine to raise water by fire.

If plants were not in this manner supplied with moisture, it were impossible for them to subsist under the scorching heats within the Tropics, where they have no rain for many months together; for though the dews are much greater there than in these more northern climates, yet, doubtless, where the heat so much exceeds ours, the whole quantity evaporated in a day there, does as far exceed the quantity that falls by night in dew, as the quantity evaporated here in a summer's day is found to exceed the quantity of dew which falls in the night.

But the dew which falls in the hot summer season, cannot possibly be of any benefit to the roots of trees, because it is remanded back from the earth by the following day's heat, before so small a quantity of moisture can have soaked to any considerable depth.

The great benefit therefore of dew in hot weather must be, by being plentifully imbibed into vegetables, thereby not only refreshing them for the present, but also furnishing them with a fresh supply of moisture towards the great expences of the succeeding day.

It is therefore probable, that the roots of trees and plants are thus, by means of the sun's warmth, constantly irrigated with fresh supplies of moisture, which, by the same means, insinuates itself with some vigour into the roots; for if the moisture of the earth were not thus actuated, the roots must then receive all their nourishment merely by imbibing the next adjoining moisture from the earth; and consequently the shell of the earth, next the surface of the roots, would always be considerably drier the nearer it is to the root, which I have not observed to be so.

But when, towards the latter end of October, the vigour of the sun's influence is so much abated, that the first thermometer was fallen to three degrees above the freezing point, the second to ten degrees, the fifth to fourteen degrees, and the sixth to sixteen degrees; then the brisk undulations of the moisture of the earth, and also of the ascending sap, much abating, the leaves faded and fell off.

The greatest degree of cold, in the following winter, was in the first twelve days of November; during which time, the spirit in the first thermometer was fallen four

degrees below the freezing point; the deepest thermometer ten degrees; the ice on ponds was an inch thick; the sun's greatest warmth at the winter solstice, in a very serene, calm, frosty day, was, against a south aspect of a wall, nineteen degrees, and, in a free open air, but eleven degrees above the freezing point.

From the tenth of January to the twenty-ninth of March was a very dry season, when the green wheat was generally the finest that was ever remembered: but from the twenty-ninth of March 1725, to the twenty-ninth of September following, it rained more or less every day, except ten or twelve days about the beginning of July; and that whole season continued so very cool, that the spirit in the first thermometer rose but to 24 degrees, except now and then a short interval of sun-shine; the second only to twenty, the fifth and sixth to twenty-four, and twenty-three degrees, with very little variation; so that, during this whole summer, those parts of roots which were two feet under ground, had three or four degrees more warmth than those which were but two inches under ground; and, at a medium, the general degree of heat through this whole summer, both above and under ground, was not greater than the middle of the preceding September.

THERMOSCOPE, an instrument shewing the changes happening in the air with respect to heat and cold.

The word thermoscope is generally used indifferently with that of thermometer, though there is some difference in the literal import of the two; the first signifying an instrument that shews, or exhibits, the changes of heat, &c. to the eye; and the latter an instrument that measures those changes; on which foundation the thermometer should be a more accurate thermoscope, &c. This difference the excellent Wolfius taking hold of, describes all the thermometers in use as thermoscopes; shewing that none of them properly measures the heat, &c. none of them do more than indicate the same. Though their different heights, yesterday and to-day, shew a difference of heat, yet, since they do not discover the ratio of yesterday's heat to to-day's, they are not strictly thermometers.

THESEA, in antiquity, feasts celebrated, by the Athenians, in honour of Theseus.

THESIS, a general proposition which a person advances and offers to maintain.

In colleges it is frequent to have placards, containing a number of them, in theology, in medicine, in philosophy, in law, &c.

THEURGY, a name given to that part of magic called white magic, or the white art. Those who have written of magic have divided it into three kinds; the first is theurgy, as operating by divine means: the second, natural magic; performed by the powers of nature: and the third, necromancy; which they imagined proceeded from invoking dæmons.

THIGH, in anatomy, that part of the body of men, quadrupeds, and birds, between the leg and the trunk.

The several parts of the thigh have different names: the fore and upper part is joined to the groin, or inguen; the side makes the haunch, or hip, coxa, coxendix; the upper hind part, the buttock, clunis: the lower and hind part of the ham, poples, of *post* and *plico*, because it bends backwards; and the fore-part of the knee, genu, of the Greeks γονυ, which signifies the same. The bone of the thigh is the largest and strongest of the whole human body, as being to bear the whole burthen thereof; whence its name semur, of *fero*, to bear.

Fractures and Luxations of the THIGH. The thigh-bone, though the largest and stoutest in the whole body, is yet frequently broken, both near its middle and towards its ends or articulation, but more particularly near that part called its neck, near its articulation with the hip-bone; and when this is the case it is very difficult to set it, and retain it in its place. When the bone is broken in two places at once, which sometimes happens, the danger is much greater. Sometimes this bone is broken transversely, sometimes obliquely, and at other times the ends slip in a great way over one another, notwithstanding the utmost caution in setting it. It is

therefore necessary in these cases, according to Heister, besides the means that are common to all the fractures, to use a more strict and tight bandage in this than in the transverse fracture, to prevent the bones from being easily removed. When a fracture of the thigh-bone happens near the middle, or towards its lower-head, it is to be extended and replaced with the hands like other fractures, except that the extending force required is very great; and where the hands of a strong assistant are not enough, slings, napkins, or linen-bandages are to be bound round each head of the thigh, whereby the fractured bone may be extended both ways by the strength of three or four persons at once, while the surgeon cautiously reduces the fracture with his hands, and secures it with a proper bandage and dressing: and there are sometimes cases where the joint strength of three or four men applied in this manner, is not sufficient to make the necessary extension; in which case the surgeon is obliged to have recourse to ropes and pulleys, by means of which one man will pull more forcibly and equally than several can without them: but cases that require this treatment are not common.

When the neck of the thigh-bone is fractured, to which, from its oblique or transverse direction, and spongy or brittle substance, it is very subject, it makes a fracture not only difficult to reduce, but such a one as can seldom be cured without leaving the limb shorter than it was before. The reasons of which are, that the fragments cannot, but with great difficulty, be pressed into their right places, by reason of the great thickness and strength of the muscles which cover them; and, that it seldom happens that the bones can be retained in their natural position, after they have been ever so well reduced; because the muscles which pass over, and are inserted below, the neck of this bone, draw its lower part upwards: to which it may be added, that it is very difficult to discover when the neck of the thigh-bone is fractured; this case being usually taken for the head of the bone being slipped out of its socket. If the fracture of the bone be accompanied with a wound, it makes the case very difficult and dangerous; and if these accidents happen to be inflicted on the neighbouring joint, death is generally the consequence, more especially when any of the large vessels are wounded.

The thigh-bone, Heister observes, is found to be capable of luxation four ways, upwards and downwards, and backwards and forwards; but it is most frequently dislocated downward and inward, towards the large foramen in the os pubis. For besides that the cartilaginous defence on the lower part of the acetabulum is not so high as on the rest, the ligamentum rotundum is ever found to give way more readily in that part than in any other; and, lastly, the adjacent muscles are found to be weakest on this part. And there is besides, a certain eminence in this edge of the acetabulum which prevents the head of the bone from falling back again easily into its right place when once it is got this way out of it. But if the head of this bone be displaced outwards, it generally slips upwards at the same time, it being scarce possible but that the very strong muscles of the thigh must then draw the bone upwards; and there is no eminence in this edge of the acetabulum to resist the head of the bone in that passage.

When the thigh is dislocated forwards and downwards, which is what most usually is the case, the leg hangs straddling outward, and is longer than the other; the knee and foot also both turn outwards, and the head of the bone itself will be felt near the lower part of the inguen and os pubis. Sometimes there is a suppression of urine in this case, which is occasioned by some nerve which communicates with the bladder being violently compressed; in the buttock there also may be perceived a cavity from the trochanter major, and the rest of the bones being displaced; and if the thigh-bone be not timely reduced into its acetabulum, the whole limb withers soon afterwards. The patient, for this reason, can bear little or no stress upon that limb, but must always incline and throw the weight of his body upon the other: when he moves forward, he must move that limb in form of a semicircle, and support his body by crutches under the arms: though there are not wanting particu-

lar cases where the head of the luxated thigh-bone has grown so firmly to the adjacent part, without the acetabulum, as to become, in process of time, so strong as to support the body without sticks, though the person could not, in any of the cases that have been known of this kind, walk without halting.

If the thigh-bone be displaced backward, it is usually drawn upward also, as before observed, at the same time; hence there will be perceived, in this case, a cavity behind the inguen, and a tumour upon the buttock, because the head, and trochanter of this bone, will be placed there. The tumour on the buttock being thrust upward, the limb will become shorter than before, and the foot will be inclined to turn inwards. The heel will not touch the ground, but the person seem to stand upon his toes; and lastly, the luxated limb will be much more easily bent than extended.

It is extremely rare that the thigh is luxated forward or backward, without being also drawn upward or downward; but if it should so happen, it will yet evidently be discovered by the rules before given, and by considering the nature of the articulation of the bone: as it is, however, at best very difficult to discover when the thigh-bone is dislocated, and when it is fractured, either by feeling or inspecting, because of the great thickness of the muscles and integuments; it is therefore a matter of some consequence to propose the signs by which one of these cases may be known from the other. There is reason to judge the thigh-bone to be luxated when we find the ligaments of the bone have been relaxed by some preceding congestion of humours, when no external violence has been exerted upon it, when neither violent pain, tumours, nor inflammation follow; and lastly, when the whole limb may be bent, and turned about at the acetabulum, without the surgeon's discovering any grating or crushing of the bones; and the contrary of these signs, which are what usually take place, in what have been used to be called luxations of this bone, are very strong indications of a fracture.

When the bone is found to be really dislocated, it is to be reduced in a method agreeable to the nature and direction of the dislocation. When it is displaced forward and downward, the patient is to be laid flat upon his back on a table; then a linen napkin, or strong sling, is to be made fast about the groin, over the part affected, so that one end of the sling may come over the belly, and the other over the nates and back, to be both tied together in a knot upon the spine of the os ileum, and afterwards either fastened to a hook fixed in some post, or held firm by some assistance: in like manner, at the bottom of the thigh, a little above the knee, there must be fastened another napkin or sling, or else the girt of Hildanus, with a compress between it and the thigh; both these slings being drawn tight, the thigh is to be extended, but that not vehemently, but only so much as is sufficient to draw the bone out of its sinus, that it may be replaced into its proper acetabulum by the surgeon's hands; to this purpose the surgeon is, with one hand to press the head of the thigh-bone outward, while the other conducts the knee inward. Or the reduction may be made by napkins fastened about the thigh near its extremities, in the manner of slings, and the limb extended that way, the knee being at the same time pressed inward by the hands.

If these methods are not sufficient, it will be necessary to have recourse to the polyspaston, or pulley, well known to the surgeons on these occasions. This is to be the method of reduction of the thigh-bone when it is dislocated forward; but when it is found to be luxated backward, the patient is to be placed flat on a table, with his face downward; the thigh is then to be extended more strongly than in the former case, and the reduction is to be performed by the surgeon's hand, an assistant all the while turning the limb somewhat inwards; and by this method the head of the thigh-bone generally slips very readily from this sort of dislocation into its proper place. The limb is then to be secured with proper bandages, and the patient to be kept to his bed for three or four weeks.

THIMBLE, an instrument made of brass, silver, iron, &c. put on the finger to thrust a needle through any

any cloth, filk, &c. used by all seamstresses, taylor, &c.

The art of thimble-making was brought from Holland, by Mr. John Lofting, a Dutchman, in 1695, who set up a workshop at Islington, and practised it with success.

Thimbles are made of shruff, or old hammered brass, the best being too dear, and the ordinary too brittle.

This they melt and cast in a sort of sand, procured only at Highgate, with which and red okre are made mould and cores, and in them they usually cast six grofs at a cast, and about six or seven of these casts in a day. They are cast in double rows, and, when cold, taken out and cut off with greasy shears.

Then boys take out the cores from the inside with a pointed piece of iron, which cores were made by them, every core having a nail with a broad head in it, which head keeps it from the mould, and makes the hollow to cast it in. This done, they are put into a barrel as they do shot, and turned round with a horse, till they rub the sand one from another.

Thus far the foundery, in which are employed six persons: first, the founder and two men make the moulds ready. Secondly, two boys make cores, for each thimble one. Thirdly, one that blows the bellows. From hence they are carried to the mill to be turned.

First, the inside, which works with an instrument to the bottom, while its hold lasts, and flies back, when let loose. Secondly, the outside, which with a coarser engine called a rough turning, is made pretty smooth at one stroke; and afterwards with a finer engine both the side and bottom are at one stroke made very smooth. Then some saw-dust or filings of horn combs are put half way into each thimble, and upon it an iron punch, and then, with one blow against a studded steel, the hollow of the bottom is made.

After this with an engine the sides have the hollow made, and in this engine is their chief secret, and they can work off with it thirty or forty grofs in a day. This done, they are again polished on the inside. Then the rim, whether a single or double one, are turned at one stroke, and all these turnings are performed with five men and three boys.

After this, they are again turned in the barrel with saw-dust or bran to scour them very bright, and so they are complete thimbles. Thus finished, they are sorted, and put six together one in another; and six of these half dozens are wrapped up in a blue paper; and four of these papers, making a grofs, are wrapped up in another paper, and tied with a packthread, which makes them almost a square, and are sold by the first maker at four or five shillings the grofs.

THINKING, *Cogitatio*, a general name for any act or open action of the mind. When the mind turns to view inwards upon itself, the first idea that offers, says Mr. Locke, is thinking, wherein it observes a great variety of modifications, and thereof frames to itself distinct ideas. Thus, the perception annexed to an impression on the body made by an external object, is called sensation. When an idea recurs without the presence of the object, it is called remembrance. When sought after by the mind, and brought again to view, it is called recollection. When held long there under attentive consideration, it is contemplation. When ideas float in the mind with regard or reflection, it is called a revery; when they are taken express notice of, and as it were registered in the memory, it is called attention; and when the mind fixes its view on any one idea, and considers it on all sides, it is study and intention. These are the most obvious modes of thinking; but there are several others yet, and, doubtless, the mind is capable of infinite others, which we have no notion at all of. The Cartesians hold that it is impossible to conceive a mind which does not think, thought alone being the essence of the mind; and that there is no time when the soul does not think: but this doctrine is overturned by Mr. Locke, who shews that in sleep, without dreaming, there is an entire recession of all the modes of thinking.

The school philosophers usually divide thinking, with regard to the object it is employed about, into under-

standing and willing, which are therefore said to be two powers or faculties of the human mind. Intellectual thinking is further subdivided into divers kinds. Thus, when the mind merely apprehends or takes notice of a thing, it is called perception. When it affirms or denies a thing, judgment: when it gathers or infers a thing from others given, reasoning; and when it disposes its own thoughts or ideas in order, method. Willing or volatile knowledge admits of infinite different modifications or determinations. Some authors extend the idea of thinking further; and consider it as existing in God, angels, men, and brutes; and divide it into divine, angelical, human, and animal or sensitive. The two first we know little or nothing of; the third is what we have already been treating of; and, as to animal or sensitive thought, it is defined to be an action of the soul attending to an external object, effected by means of the animal spirits duly agitated in the brain to excite an idea.

THIRD, in music, a concord resulting from a mixture of two sounds, containing an interval of two degrees.

It is called third, as containing three terms or sounds, between the extremes. The third, in Italian *terza*, in French *tierce*, in Latin *tertia*, has no general name in the Greek: it is the first of the imperfect concords, that is, of such as admit of majority and minority, without ceasing to be concords. And hence it is distinguished into two kinds. The first, which the Italians call *ditono*, from the Greek *ditonos*, or *terza maggiore*, and the greater third, is composed diatonically of three terms or sounds, containing two degrees or intervals, one of which, in the antient system, is a greater tone, and the other, a lesser tone; but, in the modern temperate system, they are both equal, as *ut, re, mi*; or *ut mi*.

Chromatically it is composed of four semi-tones, two of which are greater, and the third less; it takes its form from the ratio sesquiquarta, 4:5.

The second third, which the Italians call *trihemituano*, or *semi-ditono*, or *terza minore*, and we lesser third, is composed like the former, of three sounds or terms, and two degrees or intervals; but these degrees, diatonically, are only a greater tone and semi-tone.

Chromatically it is composed of three tones, two greater and one less; as *re, mi, fa*; or *re, fa*.

It takes its form from the ratio sesquiquinta, 5:6.

Both these thirds are of admirable use in melody, and make, as it were, the foundation and life of harmony.

THIRD POINT, or TIERCE POINT, in architecture, the point of section in the vertex of an equilateral triangle.

Arches or vaults of the third point, called by the Italians *di terzo acuto*, are those consisting of two arches of a circle meeting in an angle a-top.

THIRST, a painful sensation, occasioned by a preternatural vellication of the nerves of the throat or fauces, and producing a desire of drinking.

Rohault accounts for thirst thus; the stomach liquor which ordinarily resolves into a thick vapour, and ascends from the stomach up into the throat, to moisten it, being too much warmed and agitated, either from a want of some other liquor to temper and dilute it, or from any other cause, becoming converted into too thin, subtle and penetrating vapour, is so far from moistening and cooling the throat, that on the contrary it dries and heats it, and hence that motion in the nerves, the sensation of which we call thirst: thirst sometimes also arises from a mere dryness of the part; and sometimes from sharp salts, more immediately vellicating the fibres of the throat.

There are various kinds of liquor which quench thirst, some by tempering the stomach liquor; others by diluting, and even dissolving the salt; and others by moistening and supplying the fibres.—Acids are peculiarly fitted for that end.

Thirst is sometimes eluded by rolling a leaden bullet or pebble in the mouth, which occasions an extraordinary issue of saliva to moisten the throat, &c.

THISTLE, *Carduus*, in botany. See the article CARDUUS.

THISTLE Fly, in natural history, a small fly produced from a fly-worm, hatching in the protuberances of the *carduus hæmorrhoidalis*. In the protuberances of this thistle, while they are closed in all parts, the worm of this fly, from whose injuring it, at the time of depositing the egg from which it was hatched, the protuberances arose, undergoes its last transformation. It here makes of its own skin a shell, in form of an egg, within which it puts on the nymph state. When this nymph becomes a living fly, the least part of its difficulty is the finding its way out of this shell; it has a much stronger prison than that, and before it can obtain its liberty, must force its way through the much more closely compacted fibres of the protuberance of the vegetable. It has, however, no other means of doing this difficult and laborious work but that of inflating its head, and throwing out the bladder or muzzle with which all these creatures are, by bountiful nature, provided in this state.

This is a difficult operation, and many of the creatures perish in the attempt; but, what much forwards the success of it, in many cases, is, that the stalk of the thistle often becomes naturally half rotten before the time of the fly's egress. *Reaumur, Hist. Inf.*

Order of the THISTLE, or of **St. ANDREW**, a military order of knighthood in Scotland, the rise and institution of which is variously related by different authors: Lesley, bishop of Ross, reports, that the night before the battle between Athelstan king of Northumberland, and Hungus king of the Picts, a bright cross, in form of that whereon St. Andrew, the tutelar saint of Scotland, suffered martyrdom, appeared to Hungus, who having gained the victory, ever after bore the figure of the cross on his banners. Others assert that Achaius king of Scotland, first instituted this order, after having made the famous league offensive and defensive with Charlemagne king of France. But although the thistle had been acknowledged as the symbol of the kingdom of Scotland from the reign of Achaius, yet some refer the beginning of this order to the reign of Charles VII. of France. Others place the foundation of it as low as the year 1500.

The chief and principal ensign is a gold collar composed of thistles and sprigs of rue interlinked with amulets of gold, having pendent thereunto the image of St. Andrew with his cross, and the motto *Nemo Me Impune Lacesset*; "Nobody shall provoke me unpunished."

The ordinary or common ensign worn by the knights, is a star of four silver points, and over them a green circle, bordered and lettered with gold, containing the said motto, and in the center is a thistle, proper; all which is embroidered on their left breast, and worn with the collar, with a green ribband over the left shoulder, and brought under the right arm; pendent thereto is the image of St. Andrew, with his cross, in a purple robe, with an oval of gold enamelled vert, with the former motto: but sometimes they wear, enriched in the same manner, a thistle crowned.

About the time of the Reformation, this order was dropped, till James II. of England resumed it, by creating eight knights: however, the Revolution unsettled it again, and it lay neglected till queen Anne, in 1703, restored it to the primitive design, of twelve knights of St. Andrew. King George I. in the first of his reign, confirmed the statutes signed by queen Anne, with the addition of several more, among which was that of adding rays of glory to surround the figure of St. Andrew, which hangs at the collar: and though from the Reformation to George I. both elections and installments had been dispensed with, his majesty ordered that chapters of election should, for the future, be held in the royal presence; to which end he ordered the great wardrobe to provide the knights brethren, and officers, with such mantles as the statutes of the said order appointed.

THLASPI, in botany, &c. a plant with oblong narrow undivided leaves joined immediately to the stalks, on the tops of which grow numerous tetrapetalous flowers, each of which is followed by a short flat seed-vessel divided transversely into two cells.

THLASPI arvense siliquis latis, treacle-mustard, with roundish-pointed jagged leaves, and broad capsules con-

taining about four seeds in each cell. It is annual, and grows wild in corn-fields.

THLASPI arvense, vaccariæ incano folio majus, Mithridate mustard, with hoary sharp-pointed leaves shaped like an arrow-head; and only one seed in each cell. It is biennial, and grows in fields and open clayey grounds.

The seeds of these plants have an acrid biting taste, approaching to that of the common mustard; with which they agree nearly in their pharmaceutic properties, their pungent matter being totally extracted by water, only partially by rectified spirit, and being elevated by water in distillation. They have, joined to their acrimony, an unpleasant flavour, somewhat of the garlic or onion kind; and this they give out to spirituous as well as watery menstua. They are rarely made use of any otherwise than as ingredients in the compositions whose names they bear: though some recommend them in different disorders, preferably to the common mustard.

THLIPSIS, *ῥαλψις*, a compression of the stomach from food, which is offensive only by its quantity; and not endued with any remarkable quality; or from a conflux of humours, void of acrimony, into the part.

THOMÆANS, **THOMEANS**, **THOMISTS**, or *Christians of St. THOMAS*, a people of the East Indies, who, according to tradition, received the Gospel from St. Thomas. Upon the arrival of the Portuguese at Calicut, in their first voyage to the Indies, they met with ancient Christians, who pretended to be descended from those converted by St. Thomas.

The Thomæans being informed of a new people arrived among them, who bore a particular veneration for the cross, sent ambassadors to them, to make an alliance with them, and to solicit their assistance against the Gentile princes, by whom they were greatly oppressed. A mixture of opinions, with a total interruption of pastors, sometimes for several years together, occasioned that horrible chaos their religion was in, at the arrival of the Portuguese; for a specimen whereof we shall add their manner of celebrating the Eucharist: Over their altar was a kind of gallery; and while the priest was saying the beginning of the office below, a cake of flour of rice was frying in oil, or butter, above: when enough, the cake was let down in a basket upon the altar, where the priest consecrated it: as to the other species, for wine they used a kind of brandy or arrack, variously prepared in that country. Nor was their ordination much more regular; the archdeacon, who was sometimes more respected than the bishop himself, frequently ordained priests: their other abuses were infinite. The Portuguese, for these two last centuries, have laboured the reformation of this church, and have employed both the ecclesiastic and secular power therein: for this end they have called the Thomæan bishops to the council at Goa, have instructed, charged them, &c. and even sent them for instruction to Portugal and Rome; but finding that they were still apt to relapse at their return, and that no good was like to be done with them, they resolved to exclude them once for all, and to appoint an European bishop in their room. These proceedings have rendered the Portuguese infinitely odious to the Thomæans.

St. THOMAS'S DAY, a festival of the Christian church, observed on December 21, in commemoration of St. Thomas the apostle.

St. THOMAS of Canterbury's Day, a festival of the Romish church, observed on December 29, in memory of Thomas Becket, archbishop of Canterbury, who was murdered, or, as the Romanists say, martyred, in the reign of king Henry II.

THOMISM, or **THOMATISM**, the doctrine of St. Thomas Aquinas, and his followers the Thomists, chiefly with regard to predestination and grace. There is some doubt what the true genuine Thomism is, but there are authors who distinguish the Thomism of St. Thomas from that of the Dominicans. Others again make Thomism no other than a kind of Jansenism disguised: but Jansenism, it is known, has been condemned by the popes, which pure Thomism never was:

in effect, the writings of Alvarez and Lemos, who were appointed by their order to lay down and defend, before the holy see, the dogmata of their school, have since been reputed the rule of pure Thomism. The modern school has abandoned many of the antient Thomists, whose sentiments and expressions appeared to Alvarez too hard; and the new Thomists, who pass the bounds marked by these two doctors, cannot give their opinions for the sentiments of the school of St. Thomas, which the pope has forbid being censured. Those two authors distinguish four classes of Thomists: the first, which they reject, destroys or takes away liberty; the second and third do not differ from Molina; the last, which Alvarez embraces, admits of a physical pre-motion or predestination, which is a complement of the active power, whereby it passes from the first act into the second, that is, from complete and next power to action. The pre-motion they hold is offered in sufficient grace, sufficient grace is given to all men, and that they have a complete independent, next power not to act, and even to reject the most efficacious grace.

THOMISTS, a sect of school divines, who maintain Thomism.

THORACIC, *Thoracicus*, a name given to two branches of the axillary artery, on account of their conveying the blood into some parts of the thorax.

The thoracic arteries are distinguished into upper and lower. There are likewise thoracic veins, upper and under, destined for the conveyance of the blood from the thorax to the axillary vein.

THORACIC DUCT, or **CHYLIFEROUS DUCT**, a very slender canal, receiving the chyle from the chyliferous vessels, and the lymph from the lymphatics, and carrying them to the thorax, and usually through it to the subclavian vein. The beginning of this duct is in the reservoir or receptaculum chyli, which is situated in the left side of the upper vertebra of the loins, under the aorta, and the vessels of the left kidney; the rest of the duct has some resemblance of a sack or bag, and is larger and more irregular in its figure. Its end is usually in the subclavian vein; sometimes in the jugular. In dogs, and many other animals, its progress is under the aorta; but in the human body it ascends along the right side of the vertebra of the back, and passes between the aorta and the vena azygos, sometimes with a simple trunk, sometimes divided into two: its breadth, where divided, is about that of a wheat-straw.

The best manner of demonstrating it in animals, is to feed a dog well, and then to strangle him; and as soon as the body is opened, to tie it up with a thread in the breast, just by the subclavian; by this means the cistern, or receptacle of the chyle, and the chyliferous vessels and lymphatics are all exposed evidently to view at once. In a human body they may also be observed any time after death, by injecting, according to Salzman, wax, or any fluid, or indeed only by inflating the great lymphatic vessel, which runs by the left emulgent vein; or otherwise, if, according to Henninger, an injection, or barely an inflation, be made into a lacteal of the second order, to be traced out in the middle of the mesentery; or, finally, if the pleura be carefully cut between the aorta and the vena azygos, the duct will usually be easily found there. It is composed of a fine, thin, and pellucid membrane, and within it there are valves, as in the lacteals and lymphatics, which prevent the reflux of the chyle. There are more of these in the human body than in beasts; and, finally, there is a semilunar valve, closing its extremity under the subclavian.

The use of the thoracic duct is to carry the chyle to the blood, through the thorax, as it receives it from the receptacle, and with it the lymph from the lymphatics.

THORAX, in anatomy, that part of the human body which forms the capacity of the breast, and wherein are included the heart and lungs.

All that lies between the basis of the neck and the diaphragm, or midriff, that is, down to the last ribs, is called the thorax or chest. The fore-part of the thorax is called the breast; in it are the claviculæ or channel-bones, and the sternum or breast-bone, which is in the

middle; it begins at the claviculæ, and terminates in the cartilago xiphoides or sword-like cartilage. Under the sternum lies the mediastinum, and the heart in its pericardium. The mammæ or breasts are two round tumours, which appear upon the fore-part of the chest, under which are situated part of the ribs, the pleura, and the lungs; there stands upon their center a little protuberance called papilla or nipple, which is encompassed by a reddish circle called arcola. The hollow in the middle of the breast, below the breasts, is called scrobiculus cordis. The hinder part of the thorax is called the back, composed of twelve vertebræ or joints, and two scapulæ or shoulder-blades, which are the two upper parts of the back on the sides of the vertebræ. The lateral parts of the thorax are called peristerna.

The uses of the parts of the thorax in general, are their serving to respiration and the circulation of the blood, in both sexes; and in women, to the producing milk.

Wounds of the THORAX, are, by Heister, divided into three sorts. The wound is inflicted either upon the external parts of the thorax; or else it penetrates into the cavity of the thorax, without injuring any of its contents; or, lastly, the contents of the thorax also partake of the wound. That the wound terminates in the exterior parts, and does not penetrate into the cavity of the thorax, may be discovered by several methods, as by the sight, by hearing whether any sound proceeds from the wound at the time of inspiration, by feeling whether the finger or probe meets with any resistance in attempting to pass it into the cavity of the thorax, by injecting warm water, which, in this case, will return upon you; by the absence of bad symptoms, which always attend a wound that penetrates. When, by these methods, you are fully satisfied that it does not penetrate, it may be dressed with a digestive ointment, or some vulnerary balsam, and treated according to the method directed in the cure of slight wounds.

But when the wound penetrates into the thorax, and a large quantity of blood falls into the cavity thereof, then the office of respiration, and the course of the blood through the lungs, will certainly be impeded; and the blood, by frequent delays and obstructions, being entirely inspissated in the lungs, life can no longer be supported: but where the quantity of extravasated blood is not large enough to obstruct the lungs in their office, the chief danger that the patient labours under, is that the extravasated blood should putrify by degrees, and corrupt the contents of the thorax, which will bring on very bad symptoms, and in a short time death.

The following symptoms discover an extravasation of blood in the thorax: if there is a great difficulty of breathing except when the patient is placed in an erect posture; if the patient lies easiest upon his back, or wounded side; if he feels a weight upon the diaphragm; if he perceives the undulation of a fluid upon turning the body round; and, lastly, if there has been little or no discharge of blood by the wound. When it appears by these symptoms that there is a collection of blood in the thorax, the greatest diligence is required to get it out; therefore when the wound is inflicted upon the middle or lower part of the thorax, and has not a very narrow opening, it will be convenient to lay the patient upon the wounded side, advising him to fetch his breath as deep as he can, or to cough. If the current of blood is obstructed by any thick grumous parts, they must be removed with a probe or the finger, or drawn out with a syringe. If the blood is become too thick to flow out of the wound, attenuating injections must be used, made of a decoction of barley-water, with the addition of some common honey, or honey of roses, and a small quantity of soap; this is to be injected into the cavity of the thorax, and then the patient is to be so situated as to let it run out again: this operation is to be repeated, till it appears that all the grumous blood is washed away. But if the wound is so narrow or oblique, that this method cannot be prosecuted, the wound should be enlarged, being careful not to fatigue the patient too much, by endeavouring to discharge all the

extravasated blood at one time, keeping the wound open, dressing it with proper plasters and compresses, securing the whole with a scapulary, and repeating this method of dressing, till the discharge shall entirely cease, and the external wound can be conveniently healed. When a wound is made in the upper part of the breast, no posture will satisfy the intention of discharging the extravasated blood, but standing upon the head; an opening ought therefore to be made in the lower part of the thorax, called paracentesis.

The cavity of the thorax being thus cleansed, the wound is to be dressed but once every day: each dressing should be performed with all possible expedition, and the utmost diligence should be used to guard the contents of the thorax from the external air. At the time of dressing, a chaffing-dish of hot coals should be held near the wound, to warm and thin the air: and if too great a quantity of air is already got into the cavity of the thorax, it must be drawn out with a syphon. When any of the contents of the thorax is wounded, as the heart, the aorta, the vena cava, the pulmonary artery or vein, the mediastinum, or a large portion of the lungs, death comes too suddenly to give the surgeon room to exercise his art. On the other hand, when the lungs are only slightly wounded, that is, when only the ramifications of the pulmonary vein and aspera arteria are divided, the case is very dangerous, but not always mortal; though persons who recover after wounds of this kind, are more obliged to the soundness of their constitution, than their surgeon's skill.

THORNBACK, in ichthyology, the prickly raia, with tuberculose teeth, and a transverse cartilage in the belly.

The head and body are very flat and depressed; the figure of the body, exclusive of the tail, is nearly square; the tail is long and slender, but a little depressed or flattened; the belly is altogether plane, but rises a little in the middle into a convexity; the eyes stand on the uppermost part of the body, at a considerable distance from the rostrum, and are a little protuberant, and covered with a simple and naked skin; behind each eye there is a single oblong foramen, that runs transversely, and its anterior side is striated, and serves as a valve to close up almost the whole aperture; the mouth is situated on the under side of the body, and lies in a transverse direction, is very large, and stands at the same distance from the extremity of the rostrum as the eyes do.

THOUGHT, or **SENTIMENT**, a general name for all the ideas consequent on the operations of the mind, and even for the operations themselves. See **IDEA** and **THINKING**.

THOUGHTS, in a boat, a name given by seamen to the benches on which the men sit down to row.

THOWLES, is also a word used by seamen for those pins in the gunnel of a boat, between which the men put their oars, when they row.

THRASHING, or **THRESHING**, *Flagellatio*, in agriculture, the art of beating the corn out of the ears.

There are two ways of separating corn from the ear; the first by beating it with a flail, which is properly what is called thrashing. The other method, still practised in several countries, is to make mules, or horses, trample on it, backwards and forwards; this is properly what the ancients called tritura and trituratio. The Hebrews used oxen therein, and sometimes yoked four together for this purpose. Another way among the ancients was with a kind of sledge, made of boards joined together, and loaden with stones or iron, upon which a man was mounted, and the whole drawn over the corn by horses: this instrument was called traha, or tribula. It is a rule among husbandmen, that the season for thrashing, is as soon as the corn has sweated in the heap or mow.

THRAVE, or **THREAVE**, of corn, twenty-four sheaves, or four shocks of six sheaves to the shock; though, in some countries, they only reckon twelve shocks to the thrave.

THRAUSTOMITCHES, in natural history, the name of a genus of compound earths, the bodies of which are loams composed of sand and a less viscid clay, and are therefore of a friable or crumbly texture.

The earths of this genus are generally used to make bricks, and there are several species of them. 1. A whitish one, dug in great plenty in Staffordshire, and some other countries. 2. A brownish white one, very plentiful about London. 3. A pale yellow one, common in most parts of England, at small depths. 4. A sharp rough one, of a deep yellow, dug near the town of Hedgerly, near Windsor, and commonly called Windsor loam; it is not found in any other place, and is of great value; it makes the bricks used for the iron furnaces, and serves at the glass-houses; and among the chemists, as a very strong and valuable lute; and is not only used in England, but carried to Holland and Germany, and many other parts of the world. 5. A deep, dusky, yellow one, dug in most parts of England, near the surface. 6. A hard, brown one, found at some depth in Buckinghamshire, and usually found full of small shells; it is used for covering the ridges of barns, and copings of walls; and makes very firm and durable barn-floors. 7. A light, pale, brown one, the loosest and most friable of all the species, used in many places for making the bell-founders moulds. 8. A yellowish brown one: this is common in most parts of the kingdom, and makes the fine red bricks, used for ornamenting buildings.

THREAD, in botany, is understood of those threads usually found in the middle of flowers; as in the lily, tulip, rose, &c. — There are two kinds; those which support apices are particularly called stamina, and those which have none simply threads.

The thread of the Laplanders is very fine, white, and strong, but it is of a very different nature from ours; they know nothing of flax or hemp, nor of any other plant whose stalks might supply the place of these in making thread, but theirs is made of the sinews of the rein-deer. They kill of these animals a very great number continually, partly for food, partly for the skins which they use in cloathing themselves, covering their huts, and on many other occasions; the sinews of all that they kill are carefully preserved, and delivered to the women, whose province it is to prepare this necessary matter. They beat the sinews very well, and after having steeped them a long time in water, they spin them out.

The thread they thus make is of any degree of fineness they please; but it never is any longer than the sinew from which it is made. They use this in sewing their cloaths, shoes, gloves, &c. and the trappings of their rein-deer. The threads of the same sinew are laid up together, and are all of a length; and as the different sinews afford them of very different lengths, they accordingly pick out such as the present use requires, both in regard to length and fineness. This sort of thread is made with much more labour than ours; but it is greatly superior to it on many occasions, where strength is rather required than beauty.

These people have, besides this, a way of making a sort of yarn of sheep's wool, which they weave into garters, and a sort of ribbons, used by way of ornament; but they place no value on it, because of its want of strength.

THRICHECHUS, the sea-cow, in zoology, a genus of sea animals; it has teeth in both jaws; there is no fin upon the back, and the skin is very tough, firm, and hairy.

This creature seems to be the link uniting the fish and the quadruped tribes, as the bat does the quadrupeds and birds: it grows to fifteen feet, or more, in length, and is considerably thick in proportion.

The females have, between the pectoral fins, two large, round, and fair breasts, and both sexes have the parts of generation and the navel perfectly resembling those of the human species: there is no doubt, but all the fables concerning mermaids, mermen, and syrens, took their rise from an imperfect view of this animal.

THRIPS, in the history of insects, a genus of the order of scleropstera, having the rostrum obscure, the body of a linear figure, and the wings four in number, being incumbent on the back, and straight. It is an extremely small insect, not equal to a flea in size.

THROAT,

THROAT, the anterior part of an animal between the head and the shoulders, wherein is the gullet.

Physicians include, under the word throat, all the hollow or cavity which may be seen when the mouth is wide open.

It is sometimes also called isthmus, by reason it is narrow, and bears some resemblance to those streights called by the geographers isthmi.

THROAT, in architecture, fortification, &c. See **GORGE**.

THRONE, *ἰσθῆς*, a royal seat, or chair of state, enriched with ornaments of architecture and sculpture, made of some precious matter, raised on one or more steps, and covered with a kind of canopy. Such are the thrones in the rooms of audience of kings, and other sovereigns.

THROWSTER, one who prepares raw silk for the weaver, by cleansing and twisting it.

THRUPTOMICTHES, in natural history, a genus of earths, consisting of moulds of a lax, friable texture.

Of this genus there are only two species. 1. The red thruptomicthes, frequent in many countries: but no where more plentifully than about Rowel, in Northamptonshire: it is accounted a very fertile good land, and, particularly, succeeds with crops of rye, barley, or pease. 2. The friable, brown thruptomicthes, frequent in Suffex, and in many other parts of the kingdom, and is generally accounted a poor, barren land.

THRUSH, in ornithology, two species of turdus, the one called the common thrush, and the other the missel-thrush.

The common thrush is the turdus with a white line over the eyes. This is smaller than the fieldfare; the head is small and flatted; the eyes are bright, their iris hazel; the ears patulous; the beak about half an inch long, brown and pointed; the head and back of an olive brown, spotted with a dark colour; the breast is yellow, the belly whitish, and the legs brown.

The other species of turdus, called the missel-thrush, is of a greyish yellow colour with a spotted breast, being the largest of the turdus kind.

THULE, of the ancients, supposed to be the islands of Orades.

THUMB, *Pollex*, in anatomy, one of the parts or extremities of the hand. See **HAND**.

The thumb, considered separately, has bones thicker than those of the fingers; the first of these agree in all respects with those of the metacarpus, in figure, situation, and articulation; but in its motion it is widely different. The articulation of the first with the second, and of the second with the third, are like the articulations and motions of the second and third phalanges of the other fingers.

THUNDER, a noise in the regions of the air, excited by a sudden kindling of sulphureous exhalations.

Those philosophers who maintain, that vapours are buoyed up in the air by particles of fire adhering to them, account for the phenomena of thunder and lightning in the following manner: they suppose that from the particles of sulphur, nitre, and other combustible matter, which are exhaled from the earth, and carried into the higher regions of the atmosphere, together with the ascending vapours, is formed an inflammable substance, which, when a sufficient quantity of fiery particles is separated from the vapours, by the collision of two clouds, or otherwise, takes fire, and shoots out into a train of light, greater or less, according to the strength and quantity of the materials. This opinion is certainly false; for it is impossible the vapours should be attended with such fiery particles as is here supposed: neither have we occasion to fly to such an hypothesis; for as vapours, exhaled from the surface of the water, are carried up into the atmosphere, in like manner the effluvia of solid bodies are continually ascending thither. Now we find by experiment, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles.

Thus, M. Lemery having covered up, in the earth,

about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron, tempered with water; after eight or nine hours time the earth, where it was laid, vomited up flames. Thus also, mix a small quantity of gun-powder with oil of cloves, pour gently upon this mixture two or three times as much spirit of nitre, and you will observe a bright inflammation suddenly arising from it. A mixture of the two fluids alone will take fire, the powder is added only to augment the inflammation. When, therefore, there happens to be a mixture of the effluvia of such bodies floating in the air, they ferment, kindle, and, flashing like gun-powder, occasion those explosions and streams of fire, which we call thunder and lightning.

As to the particular species of the effluvia, which compose this mixture, that cannot be exactly determined: they are thought to be chiefly sulphureous and nitrous; sulphureous, because of the sulphureous smell which lightning generally leaves behind, and of that sultry heat in the air, which is commonly the fore-runner of it; nitrous, because we do not know of any body liable to so sudden and violent an explosion as nitre is.

Dr. Lister is of opinion, that the matter both of thunder and lightning, and also of earthquakes, is the effluvia of the pyrites; as he does, that the matter of volcanos is the pyrites itself. This is a mineral that emits copious exhalations, and is exceeding apt to take fire upon the admission of moisture. See the doctor's defence of his notion in the Phil. Trans. N^o 157. He thinks this may be the reason why England is so little troubled with earthquakes, and Italy, and almost all places round the Mediterranean sea, so very much, viz. because the pyrites are rarely found in England; and, where they are, they lie very thin, in comparison of what they do in those countries; as the vast quantity of sulphur emitted from the burning mountains there, seems to shew.

The effects of thunder and lightning are owing to the sudden and violent agitation the air is put into thereby, together with the force of the explosion; and not to thunderbolts falling from the clouds, as is supposed by the vulgar.

Some are inclined to think, that thunderbolts are artificial, and that they were applied by the ancients to some use. What confirms them in their opinion is, that they are found more frequently where sepulchres have been, than in other places.

The distance the thunder is from us, may nearly be estimated by the interval of time between our seeing the lightning and hearing the thunder; for as the motion of light is so very quick, that the time it takes up in coming to us from the cloud, is not perceptible; and as that of a sound is about a thousand feet in a second; allowing a thousand feet for every second that passes between our seeing the one and hearing the other, we have the distance of the cloud, pretty nearly, from whence the thunder comes.

We sometimes see flashes of lightning, though the sky be clear and free from clouds; in this case they proceed from clouds that lie immediately below our horizon.

It has lately been found by repeated experiments that the electric matter, and that which produces thunder, are the same. We are beholden for this discovery to Mr. B. Franklin of Philadelphia.

THUNDERING LEGION, *Legio Fulminans*, was a legion in the Roman army, consisting of Christian soldiers, who, in the expedition of the emperor Marcus Aurelius against the Sarmatæ, Quadi, and Marcomanni, saved the whole army then ready to perish of thirst, by procuring, with their prayers, a very plentiful shower thereon, and at the same time a furious hail, mixed with lightning and thunder-bolts, on the enemy.

This is the account commonly given by ecclesiastical historians, and the whole history is engraven in bas-relievo's on the Antonine column. And hence arose the denomination Thunderers, though some say, that the legion those Christians were of, was called the Thundering Legion before.

THURSDAY, the fifth day of the Christian week, but the sixth of that of the Jews.

Holy **THURSDAY**, the same with Ascension-day.

Maundy

Maundy THURSDAY. See the article MAUNDY-THURSDAY.

THUYA, *Arbor Vitæ*, in botany, a genus of plants, producing male and female flowers in the same plant; the male flowers are produced in an oval katkin, placed opposite upon the common foot-stalk, each flower embracing it with its base; these come out of an oval concave scale; they have no petals, but have four stamina, which are scarce discernible; their summits adhere to the base of the scale of the empalement. The female flowers are collected in a common almost oval cone, two flowers standing opposite in each scale; they have no petals, but have a small germen, supporting a slender style, crowned by a single stigma; these are succeeded by an oblong oval cone, opening longitudinally, whose scales are almost equal, convex on the out-side, and obtuse, each containing an oblong seed.

Mr. Miller enumerates two species of these plants: the first growing naturally in Canada, Siberia, and other northern countries; and in some of the English gardens which have not been altered, there are some of these trees which are of a large size: it has a strong woody trunk, which rises to the height of forty feet or more.

The second sort grows naturally in the northern parts of China, where it rises to a considerable height; but this has not been long enough in Europe to have any trees of large size.

These trees may be propagated by seeds, layers, or cuttings. The first sort is commonly propagated by cuttings; these should be planted in September, upon a shady border, and in a loamy soil; the cuttings should be chosen from the shoots of the same year, with a small joint of the former year's wood at the bottom of each. These should be planted three or four inches deep, in proportion to their length, treading the ground close to them to prevent the admission of air. If the following spring should prove dry, there should be a little mulch laid over the surface of the ground to prevent its drying; where this is performed in time, it will save the trouble of watering the cuttings; and it will be much better for them, because when these are putting out their young fibres, if they are much watered, it will rot them while they are tender. These cuttings will be rooted enough to transplant by the next autumn, when they may be either planted in beds, or in nursery-rows to be trained up.

When they are propagated by layers, the young branches only should be laid down in autumn, which will also put out roots by the next autumn, when they may be taken up, and transplanted in the same manner as those raised from cuttings; but although these are very expeditious methods of propagating this tree, yet those who are desirous to have large trees, should always propagate them by seeds, for the plants so raised will be much preferable to the other.

The China sort is generally propagated by layers in the same way as the former, but the cuttings of this, if rightly managed, will take root very freely; but most people have over nursed them. If these are planted in September in a border of soft loam, exposed to the east, and if before the hard frosts set in, the surface of the ground is covered with old tanners bark about two inches thick, it will prevent the frost from penetrating the ground; and if this remains in the spring, it will also keep the ground moist, for if the cuttings or layers of this sort are watered too much in the spring, when they are beginning to put out young fibres, it will certainly rot them; therefore it is most advisable not to water these cuttings or layers, nor should the plants be much watered when they are transplanted, for the same reason; but as there are many plants now in England, which ripen their seeds, so those who can be supplied with them, should prefer them to the other; for, after the first two years, the seedling plants will greatly outstrip the other in growth, and the plants will be much handsomer.

These seeds should be sown soon after they are ripe, which is in the spring. They should be sown in pots, filled with soft loamy earth, and plunged into the ground in an east border, where they may have only the morning sun, observing always to keep the pots clean from

weeds. Sometimes these seeds will come up the same year, but they often lie in the ground till the next spring; therefore the pots should be put in a common hot-bed frame in winter, and in the spring the plants will come up; these must not be too much exposed to the sun the first year, and if in the next winter they are sheltered under a frame, it will be a good way to preserve them; and the spring following they may be transplanted into beds, and treated in the same way as those propagated by cuttings.

THYMALLUS, in ichthyology, the name of a fish, called in English the greyling or umber.

It is of a long flatted body, the belly is somewhat broad, and the back rigid and thin. It seldom exceeds a pound, or at the utmost a pound and a half weight. Its back is of a dusky brownish green, with a somewhat bluish cast intermixed, and its sides of a more shining gloss with an admixture of gold colour. The scales are of a sort of rhomboidal form, and the side lines are much nearer the back than the belly. The sides are variegated with black spots placed irregularly, but there are none of these near the tail. The back has two fins, and the tail is forked. The head is small, the eyes large and protuberant; the mouth is moderately large, and the upper jaw larger than the under; it has no teeth, but the whole jaws are rough like a file.

It is caught in the fresh rivers in the mountainous counties of England, and in the like situations in Germany, and other kingdoms, and is one of the finest-tasted of all the fresh-water fish. It feeds on worms, and spawns in May.

THYMUS, thyme, in botany, a low shrubby plant, consisting of numerous slender tough stalks, with little roundish leaves in pairs, and loose spikes, on the tops, of purplish or whitish labiated flowers, whose upper lip is nipt at the extremity, the lower divided into three nearly equal segments.

There are three different species of thyme enumerated in the materia medica: 1. Common thyme, with upright stalks, and dark brownish green somewhat pointed leaves; a native of the southern parts of Europe, common in our gardens, and flowering in June and July.

This herb is a moderately warm pungent aromatic. To water it imparts, by infusion, its agreeable smell, but only a weak taste, with a yellowish or brown colour: in distillation, it gives over an essential oil, in quantity about an ounce from thirty pounds of the herb in flower, of a gold yellow colour if distilled by a gentle fire, of a deep brownish red if by a strong one, of a penetrating smell resembling that of the thyme itself, but less grateful, in taste excessively hot and fiery: the remaining decoction, inspissated, leaves a bitterish, roughish, subsaline extract. The active matter, which by water is only partially dissolved, is by rectified spirit dissolved completely, tho' the tincture, in colour blackish-green, discovers less of the smell of the thyme than the watery infusion: the spirit brings over in distillation a part of its flavour, leaving an extract of a weak smell and of a penetrating camphorated pungency.

2. Mother-of-thyme, with trailing stalks, and obtuse leaves: growing wild on heaths and dry pasture grounds. This also is an elegant aromatic plant, similar to the foregoing species, but milder, and in flavour rather more grateful. Its essential oil is both in smaller quantity and less acrid, and its spirituous extract comes greatly short of the penetrating warmth and pungency of that of the other. Both the leaves themselves, and their spirituous tincture, are of a bright green colour, without any thing of the brown or blackish hue of those of the common thyme.

3. Lemon-thyme, in appearance differing little from the second sort, except that it is more upright and more bushy; a native of dry mountainous places, common in gardens, and flowering as the others in June or July. This species is less pungent than the first sort, more so than the second, and much more grateful than either: its smell in particular is remarkably different, approaching to that of lemons. Distilled with water, it yields a larger quantity than the other sorts, of a yellowish very fragrant oil of the lemon-flavour, containing nearly all the medicinal parts of the plant, for the remaining decoction

cotion is almost insipid as well as inodorous. It gives over also with rectified spirit its finer odorous matter; a less agreeable flavour, and a moderate warmth, remaining in the spirituous extract.

All these plants may be easily propagated by those who are desirous to have them in their gardens, either by slips, or by sowing their seeds in the spring. They delight in dry undunged ground, where they will propagate themselves by their trailing stalks, and require no other care but to keep them clean from weeds.

THYMUS, in anatomy, is that gland which in calves, lambs, and young animals, is called the sweet-bread.

The thymus is an oblong glandular body, round on the upper-part, and divided below into two or three lobes, of which that towards the left-hand is the largest. In the foetus, it is of a pretty large size, less in children, and very little in aged persons. In children, it is of a white colour, sometimes mixed with red; but, in an advanced age, its colour is generally dark.

The greatest part of the thymus lies between the duplicature of the superior and anterior portion of the mediastinum, and the great vessels of the heart, from whence it reaches a little higher than the tops of the two pleurae, so that some part of it is out of the cavity of the thorax; and in the foetus, and in children, it lies as much without the thorax as within it.

Its particular inward structure and secretions are not as yet sufficiently known to determine its uses, which however seem to be designed more for the foetus than adults.

THYMUS, in medicine, is used for a kind of wart growing on the parts of generation, the fundament, and several other parts of the body.

The ordinary method of curing a thymus, is by ligature and desiccative lotions, or by caustics; and if large, by incision, taking care first to secure the greater vessels, by tying them.

THYNNUS, the name of a fish, called in English the tunny or Spanish mackarel, common in the Mediterranean, and other seas, and sometimes, though not frequently, caught on the English coasts.

It is a very large fish, growing sometimes to seven or eight feet long, and more than an hundred weight. It is of a rounded and thick body, growing gradually small towards the tail, until it is at length extremely slender. It very much resembles the pelamis in its whole figure, but that it wants the oblong black streaks which that fish has on its sides, and is much larger. The back is black, or, if held in some lights, is of a shining bluish or greenish hue. Its belly and half its sides are of a silvery whiteness. Its scales are very small, its snout pointed, its jaws both of equal length, and armed each with one row of teeth. The mouth is large and black within, except that part of the palate is red. The eyes are large. The larger black fins are two in number; the foremost placed near the head, and rising out of a cavity in the back, and the other at a small distance behind that; and, in some fish of this species, of a reddish or yellowish colour; and, behind this last, there are eight, nine, or ten small fins running down the ridge of the back, at equal distances to the tail. The tail is very forked. The fins at the gills are black, small, and terminate in a point. The belly fins are placed but at a small distance behind these, and are also small; and both these, and the gill-fins, have sinuses in the body of the fish, into which they may be depressed. Behind the anus is a fin like that on the back, and behind it eight more small ones, answering to those on the back also; and the skin of the sides, near the tail, is extended into two fins, so that this part of the fish looks in some sort square. It is a good fish for the table, and is salted in vast quantities in Spain and Italy.

THYROARYTÆNOIDES, in anatomy, a muscle of the larynx, which, arising and terminating in it, serves, together with the arytenoides, to constrict it. These two muscles mutually intersect one another, and straighten the glottis; sometimes there is but one muscle; and sometimes it is different from that described here.

THYROIDE GLAND, in anatomy, is of a very singular figure, resembling that of the new moon. It adheres by its middle part, which is called by authors its isthmus, to the upper ring of the trachea, and its points or horns are turned upwards. It adheres on each part to the larynx and oesophagus.

THYROIDE CARTILAGE, one of the five cartilages that principally compose the larynx. The thyroide is the first of these cartilages, and is also called the scutiform cartilage, being of a quadrangular figure, and standing in the anterior part, where the pomum Adami, as it is usually called, makes its prominence, and the largest of the other five cartilages.

THYROSTAPHYLINUS, in anatomy, the name of a muscle of the uvula, which arising from the lateral part of the thyroide cartilage, and ascending towards the uva, becomes larger, and is inserted in the manner of an arch, in the side of the velum palatinum.

THYRSUS, in antiquity, the sceptre which the poets put into the hand of Bacchus, and wherewith they furnished the Menades in their Bacchanalia.

The thyrsus was originally a lance or spear wrapped up in vine-leaves, wherewith Bacchus is said to have armed himself and his soldiers in the Indian wars, to amuse and deceive the unpractised Indians, and make them expect no hostilities.

Hence, it was afterwards borne in the feasts and sacrifices of that god; and as the satyrs, who were Bacchus's soldiers, were supposed to have fought with it, it became a custom to represent them therewith.

TIARA, an ornament or habit wherewith the ancient Persians covered their head, and which the Armenians, and kings of Pontus, still wear on medals; these last, because descended from the Persians.

TIARA is also the name of the pope's triple crown; anciently called regnum.

TIBERIADES WATER, the water of a hot spring near Tiberiades in Egypt. Dr. Perry, when on the spot, tried some experiments on this water, which give us a much better idea of its nature, than we have from any other accounts of it. Half a dram of tartar being mixed with an ounce and a half of the water, it becomes turbid and muddy; and, after twelve hours, three parts of the whole appear like white wool, only leaving a small portion of clear water at the top. This white woolly matter, dried, produced only a small quantity of yellow ochre.

Spirit of vitriol added to the water in the same quantity, affords a large unctuous sediment of a white colour. A solution of sublimate being mixed in the same quantity, it became turbid and yellowish, and yielded an earthy sediment in a small quantity; whence it seems evident, that it contains a sal murale.

Saccharum saturni being added in the same quantity, the water deposited a lateritious sediment in a small quantity. Mixed with spirit of sal armoniac, it turns to a bluish green turbid liquor, and finally yields a woolly sediment. Sugar of violets, mixed with it, turned it to a yellowish colour; and the scrapings of galls, mixed with it, turned it to a deep purple; and on shaking this became as black as ink.

It appears from these experiments, that the water contains a good deal of a gross fixed vitriolic salt, some alum, and a sal murale. It is too salt and nauseous for internal use; but it must be of use as a bath in all cutaneous foulnesses, especially in scorbutic and leprous cases; for it will powerfully deterge, scour, and cleanse the excretory pores, and it may, by its weight and stimulus, restore them to their natural state and tone, and restore the true state of the vitiated solids in general. *Phil. Trans.* N^o. 462.

TIBIA, in anatomy, is the inner and bigger bone of the leg, called also focius majus: it is hard and firm, with a cavity in its middle; it is almost triangular; its fore and sharp edge is called the skin. In its upper extremity it has two large sinuses, tipped with a soft and subtle cartilage, called cartilago lunata, from its figure. It runs in between the extremities of the two bones, and becomes very thin at its edge, like those in the articulation of the lower jaw. It facilitates a small side

motion of the knee. The sinuses receive the two protuberances of the thigh-bone, and the production which is between the sinuses of the tibia, is received in the sinus which divides these two protuberances of the femur. By bending our knee, we bring our leg, in walking, in a straight line forwards, which, without this articulation, we could not have done: but, like those who have the misfortune to have a wooden leg, we must have brought our foot about in a semi-circle, in going even upon a plain, but more evidently upon a descent. On the side of this upper end it has a small knob, which is received into a small sinus of the fibula; and, on its fore part, a little below the patella, it has another, into which the tendons of the extensors of the leg are inserted. Its lower extremity, which is much smaller than its upper, has a remarkable process which forms the inner angle, and a pretty large sinus divided in the middle of a small protuberance; the sinus receives the convex head of the same bone. It has another shallow sinus in the side of its lower end, which receives the fibula.

TIBIALIS, or **TIBIÆUS**, in anatomy, the name of two muscles of the foot, distinguished by the epithets *anticus* and *posticus*. The *tibialis anticus*, one of the flexor muscles, has its origin from the superior and tensor surface of the tibia, and is terminated at the external os cuneiforme, and the interior part of the internal metatarsal bone. The *tibialis posticus*, or adductor muscle of the foot, has its origin in the upper part of the interosseous ligament, and its termination in the os naviculare.

TICKLING, says M. le Cat, is, in respect to the sense of feeling, what an hermaphrodite is in respect to sexes: it partakes equally almost of pleasure and pain; making one laugh, at the same time that it is intolerable; and if carried too far, frequently has bad and even fatal effects. In this sensation, the organs of feeling are affected with a light tremulous motion, which occasions all voluptuous sensations; but more lively in its degree and smarter than that which usually attends on pleasure: it proceeds from that gentle friction, which is distinguished from all other impressions on the organs, by the name of titillation.

TICKLISH, in the manege. A horse is said to be ticklish, that is too tender upon the spur, and too sensible; that does not freely fly the spurs, but in some measure resists them, throwing himself up, when they come near and prick his skin. A ticklish horse has somewhat of the ramingues, i. e. the kickers against the spurs; but with this difference, that the latter put back, leap and kick, and jerk out behind, in disobeying the spurs; whereas a ticklish horse only resists for some time, and afterwards obeys and goes much better, through the fear of a vigorous ham, when he finds the horseman stretch his leg, than he does upon being actually pricked.

TIDES, two periodical motions of the waters of the sea, called the flux and reflux, or the flow and ebb.

The cause of the tides is the attraction of the sun and moon, but chiefly of the latter; the waters of the immense ocean, forgetful, as it were, of their natural quietus, move and roll in tides, obsequious to the strong attractive power of the moon, and weaker influence of the sun.

To illustrate this, let *NESQ* (plate CXXVI. fig. 6.) represent the earth covered over with water *ABDF*; *NS* the axis of the earth, *EQ* the equator, *TR* the tropic of cancer, *tr* the tropic of capricorn, *M* the moon in her orbit, *S* the sun in his. Now since all bodies are endued with an attracting virtue, the moon will attract all the water in the nearest hemisphere *FAB*, with degrees of force which are inversely as the squares of the distances from all parts; and therefore with the strongest force where the distance is least, viz. in the point *A*, directly under her: and this attraction being in this hemisphere contrary to that of the earth, the water in all parts from *B* to *F* towards *A* will have its gravity decreasing, and be highest of all at the part *A*; and consequently must there stand higher than at the point *F*, where being more attracted by the earth, it must be heavier and nearer to the center, as is evident from the laws of hydrostatics. See the article **FLUID**.

Again, in the hemisphere *FDB*, the attraction of the moon conspires with that of the earth; but decreasing as the squares of the distances increase, the joint force of attraction will every where decrease from *F* and *B* towards *D*, the point opposite to the moon; where, again the waters will be lightest, and therefore stand highest to preserve the equilibrium. Whence it appears, that by this sum and difference of the moon's and earth's attraction, there will necessarily ensue a protuberance or swelling of the waters, which we call tides of flood, in the two points *A* and *D* directly under the moon. Also in the two points *F* and *B*, as the waters are there most attracted, so they will be heaviest, and consequently rise to the least height from the earth's surface, whence they are called tides of ebb, or the ebbing of the water.

If to the power of the moon we add that of the sun, we shall have the tides considerably augmented at the conjunction in *S*, or opposition in *H*, that is, at the new and full moons, which are called the spring-tides; as those which happen when the sun is at *O* or *P*, are called neap-tides, the waters at *A* and *D* being then lowest, because the attraction of the moon is then counterbalanced by that of the sun.

It is farther to be observed, that of the two tides of flood at *A* and *D*, that at *A* is greatest to any place *T* in northern latitude, when the moon is in the northern signs and above the horizon; for the point *A* is then nearer the zenith of the place *G*, than the opposite point *D* is to the same place at *R* twelve hours afterwards; and, consequently, the height of the tide *TG* is greater than that of the opposite tide *Rg*. The contrary of this happens, when the moon is in the southern signs.

That there are two tides of flood and two of ebb, succeeding each other alternately at about the interval of six hours, is obvious from the figure; and that they happen later each day near an hour, is owing to their exact correspondence to the motion of the moon, which daily culminates so much later. That they happen not when the moon is in the meridian, but about three hours after, is owing to the force of the moon being then greater than when in the meridian of any place; as the heat of the day is greater at three o'clock than at twelve; and the heat of the summer is greater in August, than at the 21st of June. Lastly, that the greatest spring-tides happen not at the 21st of March, and 23d of September, but in February and October, is because the sun being nearest the earth in December, his influence is then strongest, and so must quicken the time of the greatest vernal tides; and being weakest in June, the time of the autumnal tides will necessarily be retarded.

The sum of what has been said is this: if *NOPQ* (fig. 7.) be the surface of the earth *T* its center, *FKGLHCE* a circle representing the spherical surface of the waters covering the earth and affected only by the attractive power of the earth; upon placing an attracting body at *S*, the waters will no longer continue their spherical figure, but be immediately drawn into the spheroidal figure *ACBD*, in such manner, as to be depressed at *C* and *D* to *M* and *K*, and elevated from *L* and *I* to *A* and *B*; and the elevation *AL* or *BI*, is double the depression *CM* or *DK*. That if *S* be the sun, then $AP - OK = AL + KD = 25$ inches; or $11\frac{1}{2}$ feet, if *S* be the moon. That at the points *E*, *F*, *G*, *H*, (which are called the octants) the water is neither elevated nor depressed. That if any other body be placed at *O*, as the moon, in the same right-line *TS*; then by the joint influence of both *S* and *O*, the elevation at *A* and *B* will be increased, and the depression at *C* and *D* likewise. Lastly, if *S* be in the situation *S*, or vertical to the point *D*, it is plain its action to raise the water *D* will be directly contrary to that of the moon in depressing it there; wherefore the depression will not be so great as before; for the same reason the elevation at *A* and *B* will be diminished, being now only as the difference of the two forces, whereas before they were as the sum.

We shall now consider the phenomena of the tides which remain; and first, it is evident, that if *PN* be the axis of the earth, and *QO* the diameter of the equator, then the moon situated at *O*, over one of the poles, would accumulate the water over each pole, and the spheroid

the temperate zones on either side, and from this also we may understand why the tides are so small in islands that are very far distant from the shore. It is manifest that in the Atlantic ocean the water cannot rise on one shore but by descending on the other; so that, at the intermediate distant islands, it must continue at about a mean height between its elevation on the one and on the other shore.

As the tides pass over shoals, and run through straits into bays of the sea, their motion becomes more various, and their height depends on a great many circumstances. The tide that is produced on the western coast of Europe corresponds to the theory above described: thus, it is high water on the coast of Spain, Portugal, and the west of Ireland, about the time hour after the moon has passed the meridian; from thence it flows into the great channels, as it is the case with the English Channel, for example, runs up by the south of England, and another comes in by the north of Scotland; they take a considerable time to move all this way, and it is high water sooner in the places to which they first come; and it begins to fall at those places, while the two currents are yet going to others that are farther in their course. As they return they are not able to rise a tide; because the water runs faster off than it returns, till by a new tide propagated from the ocean, the return or the current is stopped, and the water begins to rise again. The tide takes twelve hours to come from the ocean to London-bridge, so that when it is high water there, a new tide is already come to its height in the ocean; and, in some intermediate places, it must be low water at the same time. In channels, therefore, and narrow seas, the progress of the motion of the waves of the sea. Our author also observes, that when the tide runs over shoals, and flows upon flat inlets, the water is raised to a great height; and because the force of the water cannot be broken upon, it is raised to a great height.

If a place communicates with two oceans, or two different ways with the same ocean, one of which is a longer way, and the other a shorter, two tides may arrive at that place in different times, which, entering with each other, may produce a great variety of phenomena. An extraordinary instance of this kind is mentioned by our author at Bosphorus, a port in the kingdom of Taurin in the East Indies, of northern latitude 25° 30'. The day in which the moon passes the equator, the water flag- nates there without any motion; as the moon moves from the equator, the water begins to rise and fall once a day; and it is high water at the rising, and low water at the falling. This daily rise and fall continues for about seven or eight days, and then decreases for many days by the same degrees, till it is a motion comes when the moon has returned to the equator. When the water has passed the equator, and declines towards the pole, the water rises and falls again, as before; but it is high water now at the rising, and low water at the falling, of the moon.

This copy of tides has been extended to the 23rd of the month, of elevations of the waters of the moon, produced by the attraction of the earth; that is, the tide pole the quantity of matter, Q , is the earth to be to the moon, q , is to 1 , that is, $Q : q :: 1 : 1$; and let us suppose the earth and moon of equal bulk, and represented by A, K, G, H , and P, D, B , and the centre of the earth at the centre of the moon B , will be to the force, F , of the moon's attraction on the surface of the earth, as the masses of matter in each, because of the equal distances T, B , and P, A , that is, $F : 1 :: 1 : 1$. Again, let B be to C as the distance of the earth to that of the moon, which is as $1 : 385000$, then will the force A, B , to the force T, C , as $1 : 365$. I. B, T, C , which is as F to A , then $T, A :: 365 : 1$, whence $F = 365$, and above we have $F = 1$, therefore $365 = 1$, and to $F :: 365 : 1$, nearly; that is, the power of the earth to raise the water at the moon C , is to that of the moon on the water A , as 1 to 365 , very nearly.

spheroid would be so poised as to have its longest axis A a coinciding with the axis of the earth P N. In this position of the spheroid, it is plain, there could be no such thing as a tide in any part of the ocean over all the earth; for every section of the spheroid, parallel to the equator, would be a circle, consequently in any parallel of latitude, the water would be at an equal distance from the earth's surface every moment of the diurnal revolution, or natural day.

Suppose the moon were removed from the direction of the earth's axis, and poised at S (Fig. 8), then will the axis of the spheroid $A B$ be turned towards S , and make an angle with the earth's axis, as $A T P$ or $B T N$. Then we observe, that since C, D , are the places of lowest water, that parallel $L K$, which passes through the point I on one side the equator, and L, M , which passes through N on the other, will divide the earth into two zones, in two of which, viz. E, N, K , and I, P, M , there will be but one tide each day, of the same kind; for instance, in the parallel E, P , a person at E will have high water, and at P low water for twelve hours after. Again, in all the zone K, M, I , there will be two tides of the same kind each day, as is evident from the figure. These limits, the arch Q, I or Q, M , is the complement of the moon's declination from the equator.

If the moon at S (Fig. 9), be over the equator, the longest axis of the spheroid $A B$ will now coincide with the plane of the equator Q, D , and the shorter axis C, D with the axis of the earth P, N . Here it is obvious, that this situation of the spheroid, the waters in the parts A, B , which respect to the axis C, D , will give the greatest difference of high and low water possible to all parts of the earth; and that there is no place but those two at the poles, N, P , where there are two tides of flood, and two of ebb every twenty-four hours. And this difference of the flux and reflux will be the same from the equator to the poles.

It has been already observed, that the greatest elevation of the waters is not when the luminary is in the meridian, but about three hours after, because the motion communicated to the waters during the arrival of the meridian is not immediately destroyed, but remains some time, and receives a further augmentation from that which is imparted for about three hours after. For the same reason, we observe, the greatest and least tides happen not on the day of the syzygy, or quadrature, but on the day after or fourth after; the sum or difference of the forces of the luminaries not being till then at a maximum. See the article SYZYGY.

Let S, P, E, G (Fig. 10) be the orbit of the moon about the earth Q, N, O, P , which as is not circular but elliptical, the centre of the earth T will not be always at an equal distance from the moon; but the mean will be sometimes nearer the earth, when at S , and sometimes farthest off, as at E . The point S is called the perigee, or perigee; and the point E the apogee, or apogee. The power of the moon in the perigee is greater, that in the apogee nearly as T, E to T, S , and consequently the greatest tides will be on the day of the perigee, or rather a few days after; for the reasons above mentioned. Such would the tides regularly be, if the whole earth were covered with deep sea; but by reason of the shoals of some places, and the narrowness of the freights, by which the tides are raised, the tides are propagated, there arises a great diversity in the tides not to be accounted for without an exact knowledge of all the circumstances of the several places where they happen; as of the position of the land, the breadth and depth of channels, &c.

That the tides may have their full motion, the ocean in which they are produced ought to be extended from east to west 90°, or a quarter of a great circle of the earth, at least; because the places where the moon raises most, and most depresses the water, are at that distance from one another. Hence it appears, that it is only in the great oceans that such tides can be produced; and why in the large Pacific ocean, they exceed those in the Atlantic ocean; hence also it is obvious, why the tides are not so great in the torrid zone, between Africa and America, where the ocean is narrower, as in

spheroid would be so posited as to have its longest axis AB coinciding with the axis of the earth PN. In this position of the spheroid, it is plain, there could be no such thing as a tide in any part of the ocean over all the earth: for every section of the spheroid, parallel to the equator, would be a circle; consequently in any parallel of latitude, the water would be at an equal distance from the earth's surface every moment of the diurnal revolution, or natural day.

Suppose the moon were removed from the direction of the earth's axis, and posited at S (*fig. 8.*) then will the axis of the aqueous spheroid AB be turned towards S, and make an angle with the earth's axis, as ATP or BTN. Then we observe, that since C, D, are the places of lowest water, that parallel IK which passes through the point I on one side the equator, and LM which passes through M on the other, will divide the earth into three zones, in two of which, viz. ENK and LPM, there will be put one tide each day, of the same kind; for instance, in the parallel EF, a person at F will have high water, and at E low water for twelve hours after. Again, in all the zone IKML, there will be two tides of the same kind each day, as is evident from the figure. These limits, or the arch QI or OM, is the complement of the moon's declination from the equator.

If the moon at S (*fig. 9.*) be over the equator, the longer axis of the spheroid AB will now coincide with the plane of the equator QO, and the shorter axis CD with the axis of the earth NP. Here it is obvious, that in this situation of the spheroid, the waters in the parts AB, with respect to those at CD, will give the greatest difference of high and low water possible to all parts of the earth; and that there is no place but those two at the poles, N, P, but what has two tides of flood, and two of ebb every twenty-four hours. And this difference of the flux and reflux will decrease from the equator to the poles.

It has been already observed, that the greatest elevation of the waters is not when the luminary is in the meridian, but about three hours after, because the motion communicated to the waters during the arrival of the meridian is not immediately destroyed, but remains some time, and receives a farther augmentation from that which is impressed for about three hours after. For the same reason, we observe, the greatest and least tides happen not on the day of the syzygy, or quadrature, but on the third or fourth after; the sum or difference of the forces of the luminaries not being till then at a maximum. See the article SYZYGY.

Let S F E G (*fig. 10*) be the orbit of the moon about the earth QNOP, which as it is not circular but elliptical, the center of the earth T will not be always at an equal distance from the moon; but the moon will be sometimes nearest the earth, as when at S, and sometimes farthest off, as at E. The point S is called the perigæum, or perigee; and the point E the apogæum, or apogee. The power of the moon in her perigee is to that in the apogee nearly as TE^3 to TS^3 ; and consequently the greatest tides will be on the day of the perigee, or rather a few days after, for the reasons above-mentioned. Such would the tides regularly be, if the whole earth were covered with deep sea; but by reason of the shoalness of some places, and the narrowness of the freights, by which the tides are, in many places, propagated, there arises a great diversity in the tides not to be accounted for without an exact knowledge of all the circumstances of the several places where they happen; as of the position of the land, the breadth and depth of channels, &c.

That the tides may have their full motion, the ocean in which they are produced ought to be extended from east to west 90° , or a quarter of a great circle of the earth, at least; because the places where the moon raises most, and most depresses the water, are at that distance from one another. Hence it appears, that it is only in the great oceans that such tides can be produced; and why, in the large Pacific ocean, they exceed those in the Atlantic ocean: hence also it is obvious, why the tides are not so great in the torrid zone, between Africa and America, where the ocean is narrower, as in

the temperate zones on either side; and from this also, we may understand why the tides are so small in islands, that are very far distant from the shores. It is manifest, that, in the Atlantic ocean, the water cannot rise on one shore but by descending on the other; so that, at the intermediate distant islands, it must continue at about a mean height betwixt its elevation on the one and on the other shore.

As the tides pass over shoals, and run through freights into bays of the sea, their motion becomes more various, and their height depends on a great many circumstances. The tide, that is produced on the western coast of Europe, corresponds to the theory above described: thus, it is high water on the coast of Spain, Portugal, and the west of Ireland, about the third hour after the moon has passed the meridian: from thence it flows into the adjacent channels, as it finds the easiest passage. One current from it, for example, runs up by the south of England, and another comes in by the north of Scotland: they take a considerable time to move all this way, and it is high-water sooner in the places to which they first come; and it begins to fall at those places, while the two currents are yet going on to others that are farther in their course. As they return, they are not able to raise a tide; because the water runs faster off than it returns, till, by a new tide propagated from the ocean, the return of the current is stopped, and the water begins to rise again. The tide takes twelve hours to come from the ocean to London-bridge, so that, when it is high water there, a new tide is already come to its height in the ocean; and, in some intermediate place, it must be low water at the same time. In channels, therefore, and narrow seas, the progress of the tides may be, in some respects, compared to the motion of the waves of the sea. Our author also observes, that when the tide runs over shoals, and flows upon flat shores, the water is raised to a greater height than in the open and deep oceans that have steep banks; because the force of its motion cannot be broke, upon these level shores, till the water rises to a greater height.

If a place communicates with two oceans, or two different ways with the same ocean, one of which is a readier and easier passage, two tides may arrive at that place in different times, which, interfering with each other, may produce a great variety of phenomena. An extraordinary instance of this kind is mentioned by our author at Bathsha, a port in the kingdom of Tunquin in the East-Indies, of northern latitude $20^\circ 50'$. The day in which the moon passes the equator, the water stagnates there without any motion: as the moon removes from the equator, the water begins to rise and fall once a day; and it is high water at the setting of the moon, and low water at her rising. This daily tide increases for about seven or eight days, and then decreases for as many days by the same degrees, till this motion ceases when the moon has returned to the equator. When she has passed the equator, and declines towards the south pole, the water rises and falls again, as before; but it is high water now at the rising, and low water at the setting, of the moon.

This theory of tides has been extended so far, as to estimate the tides, or elevations of the waters of the moon, produced by the attraction of the earth: thus, let us suppose the quantity of matter, Q, in the earth to be to that in the moon, q, as 40 to 1, that is, $Q : q :: 40 : 1$; and let us first suppose the earth and moon of equal bulk, and represented by A I K, *fig. 11.* and B D E, and the force, F, of the earth, at the surface of the moon B, will be to the force, f, of the moon at the surface of the earth, A, directly as the masses of matter in each, because of the equal distances T B and L A, that is, $F : f :: Q : q :: 40 : 1$. Again, let L B be to L C as the diameter of the earth to that of the moon, which is as 365 to 100, then will the force at B be to the force at C as L B to L C, which let be as F to f, then $F : f :: 365 : 100$, whence $F = \frac{365f}{100}$; and above we have $F = 40f$, therefore $4000f = 365f$; and so $f : f :: 365 : 4000 :: 1 : 11$ nearly; that is, the power of the earth to raise the water at the moon C, is to that of the moon at the earth A as 11 to 1, very nearly.

If the moon can raise the water here 10 feet, the earth can raise the water there to the height of 110 feet; but because the moon always turns about her axis in the same time as she revolves about the earth, the waters, if any there be, will be raised on this and the opposite side, and always continue over the same part of the moon's surface, so that there can be no different heights of water there, and consequently no tides, except what small ones may happen on account of the sun's attraction, and her various inequalities of motion, and distance from the earth.

The air, which is 860 times lighter than water, must yield in proportion more easily to the attracting force of the sun and moon; and therefore the tides will in this profound and vast aerial ocean be very considerable and important.

TIDE-WAITERS, or TIDSMEN, are inferior officers belonging to the custom-house, whose employment it is to watch or attend upon ships, until the customs be paid: they get this name from their going on board ships, on their arrival in the mouth of the Thames or other port, and so come up with the tide.

TIERCE, or TEIRCE, a measure of liquid things, as wine, oil, &c. containing the third part of a pipe, or forty-two gallons.

TIERCED, *tierce*, in heraldry, denotes the shield to be divided by any of the partition-lines, as party, coupy, tranchy, or tailly, into three equal parts of different colours or metals.

TIGE, in architecture, a French term for the shaft or fust of a column, comprehended between the astragal and the capital.

TIGER, or TYGER, *Tygris*, in zoology, makes a distinct genus of the quadruped class of animals: it has four paps placed near the navel, and its feet are adapted to climbing. Linnæus takes in the panther to this genus, and distinguishes the tyger by the name of *tygris maculis oblongis*, and the panther by that of *tygris maculis orbiculatis*.

The tyger has its name from its supposed swiftness, and has been described by almost all authors as one of the swiftest of all the wild carnivorous animals; but this has been wholly contradicted by such authors as have seen the creature, who all declare that it is a slow and sluggish animal, and is unable to overtake a man, or almost any animal that has an opportunity of running away from it. It will give two or three large leaps; but, if it do not seize its prey in these, is but ill qualified to catch it afterwards. *Ray's Syn. Quad.*

It exceeds the lion in size, and is of an unconquerable fierceness. It agrees with the panther in the variegation of its colours, but differs in the disposition of them; for in the panther the colours are disposed in round spots or eyes, and in the tyger they are disposed in long streaks.

The tyger is found in the East-Indies, in many parts of Asia, and in America; but there seems some difference in species between the Asiatic and American tygers; and possibly fuller observation may prove, that the Asiatic are swift as the ancients have described them, and the American ones, of the slowness of which we have accounts, may be a different species.

The manner of carrying off the young brood of this animal is described by Pliny as follows: The Hircanians and Indians bring up the tyger, says he, an animal of a dreadful swiftness, which is most put to the proof, when going to be taken. The whole brood, which is always very numerous, is carried off upon a horse, as swift as possible, and often removed to a fresh one. When the mother tyger finds the nest empty, and the brood gone, for the males take no care of them, she traces the scent with furious speed; and when she is arrived within hearing of the person who is carrying off her young, he throws down one of them; this she takes up in her mouth, and, as if made more swift by the load, carries it back, and then, returning, is treated in the same manner till the person gets on board a ship, and leaves her to vent her rage on the shore.

TIGER-SHELL, a beautiful species of voluta, of a dusky red colour, spotted all over with large irregular blotches of white: it is brought from the East Indies,

and is about two inches and a half in length, and about an inch in diameter.

TILE, or TYLE, among builders. See the article **TYLE**.

TILIA, the lime-tree, in botany, a genus of plants, the corolla of which consists of five oblong and obtuse petals, crenated at the points: the fruit is a coriaceous, globose, quinquelocular capsule, containing a single roundish seed in each. However, one seed only of the five usually ripens, and the very cells of the others often disappear, so that the fruit seems unilocular.

Mr. Miller enumerates four sorts of lime-trees: however, he says all of them may be easily propagated by layers, which in one year will take good root, and may then be taken off, and planted in a nursery, at four feet distance row from row, and two feet asunder in the rows. The best time to lay them down, and to remove them, is when their leaves begin to fall, that they may take root before the frost comes on, though they may be transplanted any time from September to March, in open weather; but if the soil is dry, it is much the better way to remove them in autumn, because it will save a great expence in watering, especially if the spring should prove dry. In this nursery they may remain four or five years, during which time the ground should be dug every spring, and constantly kept clear from weeds, and the large side roots pruned off, to cause them to advance in height; but the small twigs must not be pruned off from the stems, because these are absolutely necessary to detain the sap, for the augmentation of their trunks, which are apt to shoot up too slender, when they are entirely divested of all their lateral twigs. If the soil in which they are planted, be a fat loam, they will make a prodigious progress in their growth, so that in three years time they will be fit to transplant out where they are to remain.

They may also be propagated by cuttings; but as this method is not so certain as by layers, the other is generally practised. In order to obtain proper shoots for laying down, a lime-tree is cut down close to the ground, from the roots of which a great number of strong shoots are produced the following year; these will be large enough to lay down the following autumn, especially if the smallest of them are cut off close early in the summer; for when too many shoots are suffered to grow all the summer, they will be much weaker, than if only a sufficient quantity is left.

There are some persons who raise these trees from seeds, which, although it is a slower way, yet when the trees are designed to grow large, is the best method; and if they are only once transplanted, are shorter lived than those which remain in the places where they arose from the seeds, and their timber will be sounder, and grow to a much larger size.

When this method is practised, the seeds should be sown in autumn, soon after they are ripe, upon a shady border of moist light soil, where the plants will come up the following spring; but, when the seeds are kept out of the ground till spring, the plants will not come up till the year after. When the plants appear, they should be constantly kept clean from weeds till the following autumn; then they should be carefully taken up, and transplanted into a nursery, where they may grow two or three years to get strength, and then they may be planted where they are designed to remain; for the younger they are planted out the more they will thrive.

The timber of the lime-tree is used by the carvers, it being a soft light wood, as also by architects for framing the models of their buildings; the turners likewise use it for making light bowls, dishes, &c. but it is too soft for any strong purposes.

These trees will continue growing, and remain sound a great number of years, and, if planted in a good loamy soil, will grow to a considerable bulk. Mr. Miller says he measured one of those trees, which was near ten yards in girth, two feet above the ground, and was then in a thriving condition; and Sir Thomas Brown mentions one of these trees which grew in Norfolk, that was sixteen yards in circuit, a foot and a half above the ground, in height thirty yards, and in the least part of the trunk it was eight yards and a half.

TILLER,

TILLER, in husbandry, denotes a young tree, left to grow till it be felleable for timber.

TILLER of a Ship, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

In ships of war, and other large vessels, the tiller is fastened to the rudder in the gun room; and to the other end there are ropes fastened, which pass upwards to the quarter-deck, where the ship is steered by means of a wheel.

TILLAGE, in husbandry, is the opening, breaking, and dividing the ground by the spade, the plough, the hoe, or other like instruments.

The finer any land is made by tillage, the richer it will become, and the more plants it will maintain; and it has been frequently observed, that in a large field, where at some time one part of the ground has been better tilled than the rest, that part of the ground has produced the best crops, and been easily distinguished by it from the rest of the field, even six or seven crops after the time of the particular good tillage. A piece of ground being once made finer than the rest, will a long time shew the advantage of it; because the dews have more power to enrich it, they penetrating farther than the superficies, whereby the roots are able to enter. The fine parts of the earth are impregnated throughout their whole substance with some of the riches carried in by the dews, and there deposited until, by tillage, the inside of those fine parts become superficies; and as the corn drains them, they are again supplied as before; but the rough large parts cannot have that benefit, and the dews not penetrating but to their surface, they remain poor. The experiments mentioned by Mr. Evelyn, prove this beyond contest. Take of the most barren earth you can find, powder it well, and expose it abroad for a year, incessantly agitating it; and after this without any other management, this earth will be the most fertile that can be conceived, and will readily receive any plant from the farthest Indies: all vegetables will prosper and flourish in this once barren earth, and bear their fruit as kindly with us, under a due degree of artificial heat, as in their native climates.

The artificial dust will entertain plants which refuse dung and other violent applications, and has a more nutritive power than any artificial dung or compost whatsoever: and by this pulverising and exposing, the very nature of a soil may be changed, and the toughest clay made as light and friable as common light earth, and as fit for the nourishment of the tenderest plants as any other; though, in its natural condition, its pores were too small to give way to their tender roots, and had no communication one with another.

This is a sort of improvement of land that cannot be practised in the large way, in fields, &c. but as it only consists in dividing and breaking the particles of earth, and exposing them thus broken to the air, it is plain that common tillage approaches more or less to it, as more or less labour is employed; and the experiment proves, that the farmer need never fear bestowing too much tillage on any sort of ground.

TILT-BOAT, a boat covered with a tilt; that is, a cloth or tarpawling, sustained by hoops, for the sheltering of passengers.

TIMAR, a tract or portion of land, which the grand seignior grants to a person on condition of serving him in war on horse-back. Hence, those who enjoy such lands, are called timariots; who besides the above-mentioned service, pay an acknowledgment of one tenth of their revenue.

TIMBER includes all kinds of felled and seasoned woods used in the several parts of building, as carpentry, joinery, turnery, &c.

The sorts of timber are numerous; we shall only mention some of the most usual from Evelyn's Sylva, &c. —as, 1. Oak, the uses of which need no enumerating: to endure all seasons and weathers, there is no wood like it; hence its use in building ships, in posts, rails, &c. For water-works it is second to none, and where it lies exposed both to air and water, there is none equal to it.

2. Elm. This felled between November and February is all spine or heart, and no sap, and is of singular use in places where it is always wet or dry; its being tough makes it useful to wheel-wrights, mill-wrights, &c. and its not being liable to break and fly in chips, makes it fit for dressers and planks to chop on.

3. Beech: its chief use is in turnery, joinery, and upholstery, and the like, as being of a white, fine grain, and not apt to bend or split. Of late it is used for building timber; and if it lie constantly wet, is judged to outlast oak.

4. Ash: its use is almost universal; it is good for building where it may lie dry. It serves the carpenter, cooper, turner, plough-wright, wheel-wright, gardener, and at sea for oars, handspikes, and many other uses.

5. Fir, commonly known by the name of deal, is of late much used in building, especially within doors, for stairs, floors, wainscot, and most works of ornament.

6. Walnut-tree is of universal use, unless for the outsides of buildings; very fit for the joiner's use, being of a more curious brown-colour than beech, and less subject to worms.

7. Chestnut-tree, next to oak, is the timber most sought for by joiners and carpenters; it is very lasting.

8. Service-tree, used in joinery, as being of a delicate grain, and fit for curiosities: it also yields beams of considerable bigness for building.

9. Poplar, aspen: this and aspen differing very little in their nature, are of late much used instead of fir; they look as well, and are more tough and hard.

10. Alder, much used for sewers, or pipes, to convey water; when always wet, it grows hard like a stone, but soon rots, if it is alternately wet and dry.

The uses of timber are so many and so great, that the procuring a sufficient supply of it extremely well deserves the care of every state, as it must be a great disadvantage to it to be obliged to have recourse to its neighbours, and purchase, at a very considerable and continually renewed expence, what might, by an easy economy, be sufficiently supplied at home.

This economy, however, must be applied in time; for natural indolence, our love to reap the advantages of every thing ourselves, and our little care for posterity, give great room to fear succeeding ages will want wood, both for private and public exigencies. All our art should be employed on this subject with two views; the one, to preserve and cherish our growing wood; the other, to renew the trees which have been and are continually cut down.

The quantity of acorns, that the oak bears, has made many people suppose, that nature has taken care for a renewal for us, and that, of this vast quantity of seeds which annually fall, there will be always an over-sufficient supply of young trees, which will grow up in the place of the old ones: but experience proves, that this is by no means the case. The greater number of these fallen acorns are devoured by a number of different animals, for whose nourishment nature has provided that abundance of them: and, of those which escape this fate, we are to consider how few can come to good, from the natural accidents they are unavoidably exposed to; they fall on a covered ground, where dead leaves, and decayed parts of branches of trees, usually prevent their touching the earth, into which they are to shoot; or, if they can shoot here, it is merely from the surface, where they are, in their slow growth, liable, while very tender, to all the inclemencies of frosts; add to this, that it is very difficult for such tender plants, as the young seedlings of these, to find room for growth or nourishment among the every-way-spreading roots of other trees; and the continual shade, and the want of free air, must render them very weakly and irregular in their growth, even supposing them to get over all the other difficulties.

It is very certain, that timber-trees of oak are frequently met with among the underwood of forests; but we shall always find this to be the case, not in the close places but on certain spots where there has been a vacancy or opening; and that, usually, where there are not, nor have at any time been, oaks in the neighbourhood

hood of the spot. The acorns that fall from the oaks usually come to nothing, from the beforementioned accidents; and these trees, which grow at distances, are owing to the acorns brought thither by birds, and accidentally dropped there. This is an instance familiarly verified by observing, that there are frequently little bushes near woods, which, though of white-thorn, or other trees, are usually surrounded and ornamented with young oaks; the jays and the like granivorous birds are the authors of this crop; for bringing the acorns from the adjoining woods, to eat under these bushes, they drop many by the way, which they do not trouble themselves to look for on the ground, and which, having here a freer ground to take root, and an open air to grow in, seldom fail of coming to good, unless destroyed while young.

In order to the preserving our growing timber-trees, it would be a very useful law, that all, who cut down any number of oaks, should also leave a given number in good condition for after-cutting; and that no timber should be cut down, but at a proper age, in regard to the nature of the soil; since it is certain, that trees grow to their perfection at very different periods of time, in proportion to the depth of soil they have to grow in; and that, as it is, on the one hand, not for the interest of the state to suffer trees to be cut, till at their perfection for size and soundness, so, after they are arrived at that perfection, it is equally certain, that they gradually decay.

The quality of the soil the tree stands in may be necessary to be observed to this purpose; but the quantity or depth of it is the great subject of inquiry; and a great number of observations have proved, that the proper season for cutting oaks, in a soil of two feet and an half deep, is at fifty years old; those, which stand in a soil of three feet and an half deep, should not be cut down before seventy years; and those which stand in a soil of four feet and an half deep, or more than that, will increase in goodness, and in size, till they are an hundred years old: and observation has proved, that, after these several periods, the trees begin to decay.

This seems the best rule to establish, in regard to the common soils; but those which grow in a lighter or more sandy soil, may have their periods changed from these to forty, to sixty, and to eighty years at the greatest depth; and after these times it is always best to fell the wood meant for public service, whether then wanted, or not, since it is much better to keep it in public magazines, than to leave it to be daily decaying.

Heaths, and other uncultivated places, where there is no regular growth of wood, but where fern and useless plants alone seem to flourish, usually afford also some straggling trees of the oak. These, probably, have had their origin from acorns dropped by birds; but these seldom grow tall or regular, since, not having been defended from the injuries of cattle, they are usually browsed on and stunted, while young, and so become crooked and short-trunked, or pollard trees. These, though not of such value as the regular oaks, yet deserve care, both with regard to their preservation and felling, since they afford a number of trees naturally bent and formed for many parts of ship-building.

The little care usually taken of these trees, though on this occasion of great value, seems to threaten a general loss of them; but, as trees, thus naturally crooked and bent, are of value, it is a laudable attempt to try at the finding a regular method of producing such; and this is easily practicable, by following the same method by which these wild ones become so. They wholly owe their figure to the cattle's biting off their tops, while young, and afterwards biting off again the tops of the shoots from the first wound. In this manner, if a number of young trees, set apart for the experiment, have their tops cut off at two, four, six, eight, ten, and twelve feet from the ground, and, four years afterwards, the shoots from these stunted tops are again cut in the same manner, the trees will be found afterwards to grow up in all the irregularly crooked figures that can be conceived; and, by this means, a supply of naturally crooked wood may be raised for all the occasions of ship-

building, with infinitely greater ease, and more certainty, than by the method, proposed by some, of bending them down with weights tied to their tops, while young.

As to the supply of young wood in the place of what is cut down, there are some circumstances, which have not had the attention paid to them which they deserve. The spring frosts, which come on at a time when the shoots, by which nature is to raise the supply for what is cut down, are just preparing to grow, are of prodigious injury, and do not less mischief to these, than to the young shoots of garden-plants, though the distant hope of the succession to the proprietor, and usually also the distance of the place, and want of repeated observations, occasions its not being perceived. This, however, may in a great measure be guarded against. Frequent experiments, and repeated observations, prove, that the mischief done by these frosts affects, in a much greater degree, those shoots which are exposed to the north, than those which face the south; and that it is greatly more powerful against such as are wholly exposed to the wind than against such as are sheltered. These known circumstances may give the hint to a method of saving, at least, a great part of a wood to be felled, from this destruction, to its renewal, by the making it a rule to begin cutting down on the south side; and, as the whole felling is a work of some years, the standing wood of every season will defend the young shoots of the newly-cut stumps, the following spring, not only from the north exposure, but will shelter them also from the wind.

Many prudent managers have made fine estates of their coppice-woods, by regularly felling a certain portion every year, and providing for a renewal of the first cutting against the felling of the last portion, by proportioning the time of growth to the quantity to be cut every year; and there is great interest to be made of a true knowledge of the growth of wood in this manner. Whoever observes the growth of young trees will find, that the second year's growth is much more considerable than that of the first; the third year's growth is much more considerable than that of the second, and so on for many years, the yearly growth of young wood greatly increasing every season, up to a certain time or age of the tree; after which, the increase in bulk, by growth, becomes gradually less. The great advantage to be made of coppice wood would be by knowing this interesting period, and seizing on it, always to cut down the trees just at that time when they have arrived at the end of their quick growth, and so, setting nature to work with new shoots, to employ the same speed on enriching again the owner. Regular observation and experiment alone can ascertain this happy period; but any man, who has much coppice-wood upon his estate, may assure himself of it, by cutting a given quantity every year, for ten years successively, and then carefully reviewing the differences of the yearly produce.

Preserving of TIMBER.—When boards, &c. are dried, seasoned, and fixed in their places, care is to be taken to defend and preserve them; to which the smearing them with linseed-oil, tar, or the like oleaginous matter, contributes much.

The Dutch preserve their gates, port-cullices, draw-bridges, sluices, &c. by coating them over with a mixture of pitch and tar, whereon they strew small pieces of cockle and other shells, beaten almost to powder, and mixed with sea-sand, which incrusts and arms it wonderfully against all assaults of wind and weather.

Timber, felled before the sap is perfectly at rest, is very subject to the worms; to prevent or cure which, Mr. Eveyln gives us the following secret, as most approved: put common sulphur in a cucurbit, with as much aqua-fortis as will cover it three fingers deep; distil it to a dryness, which is performed by two or three rectifications.

Lay the sulphur remaining at bottom on a marble, or in a glass, and, with the oil it dissolves into, anoint the timber. This, he adds, not only infallibly prevents or cures the worminess, but preserves all kinds of woods, and even many other things, as ropes, nets, and masts, from putrefaction, either in air, water, snow, &c.

For

For such as would go a shorter way to work, two or three anointings with linseed oil may do very well. As to posts, &c. that are to stand in the ground, the burning the outsides to a coal is a great preservative.

As to the chops or clefts green timber is liable to after working, a very great eye-sore in many fine buildings, they are closed by anointing, supplying, and soaking it with the fat of powdered beef broth, twice or thrice repeated. Some carpenters use grease and sawdust mingled for the same purpose. But the former method is excellent, only it is not to be used, while the timber is green.

Seasoning of TIMBER, a term used by our husbandmen to express the preparing timber after it is felled, for cutting and working up for use.

As soon as felled, it should be laid in some dry airy place, but out of the reach of too much wind or sun, which, when in excess, will subject it to crack and fly. It is not to be set upright but laid along, one tree upon another, only with some short blocks between to give it the better airing, and prevent its becoming mouldy, which will rot the surface and produce mushrooms on it. Some persons daub the trees all over with cow-dung, which occasions their drying equally, and prevents their cracking, as they are otherwise very apt to do.

Some recommend the burying timber in the earth, as the best of all ways of seasoning it; and others have found it a fine preservative to bury their timber under the wheat in their granaries; but this cannot be made a general practice. In Norway, they season their deal planks, by laying them in salt water for three or four days, when new sawed, and then drying them in the sun; this is found a great advantage to them; but neither this, nor any thing else, can prevent their shrinking.

The seasoning timber by fire is the best way of all, for piles, and other pieces that are to stand under the earth, or water. The Venetians first found out this method, and the way they do it is this: they put the piece to be seasoned in a strong and violent flame in this; they continually turn it round by means of an engine, and take it out when it is every-where covered with a black coaly crust; by this means the internal part of the wood is so hardened, that neither earth nor water can damage it for a long time afterwards. This method is practised in many places for seasoning the posts for paling of parks, &c. and has this to recommend it, that in the very oldest ruins we have ever been acquainted with, there have been found many times pieces of charcoal, all of which has been found uninjured, though buried in the earth for many ages. *Mortimer's Husbandry.*

To measure round timber, let the mean circumference be found in feet and decimals of a foot; square it, multiply this square by the decimal 0.079577, and the product by the length. Ex. Let the mean circumference of a tree be 10.3 feet, and the length 24 feet. Then $10.3 \times 10.3 \times 0.079577 \times 24 = 202.615$, the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is 0.0795774715, and that the areas of circles are as the squares of their circumferences.

But the common way used by artificers for measuring round timber, differs much from this rule. They call one fourth part of the circumference the girt, which is by them reckoned the side of a square, whose area is equal to the area of the section of the tree; therefore they square the girt, and then multiply by the length of the tree. According to their method, the tree of the last example would be computed at 159.13 cubical feet only.

For the method of measuring round timber by the sliding rule, see RULE.

For measuring hewn or square timber, the custom is, to find the middle of the length of the tree, and there to measure its breadth, by clapping two rules to the sides of the tree, and measuring the distance betwixt them; in like manner they measure the breadth the other way. If the two be found unequal they are added together, and half their sum is taken for the true side of the square.

As to the strength of timber, Mr. Parent is the first

who has treated this subject in a scientific manner, and, in order to enforce his demonstrations, he made several experiments, with various scantlings of oak and fir. Mr. Muller, in his Treatise on Fortification, gives the following problem, to determine the strength of a scantling, whose dimensions are given. He supposes that all the fibres of the wood are strait, and of the same strength, even in its weakest part, and that the fibres are the same in the same sort of wood; and although this may not be strictly true, yet it is sufficiently near enough in practice so as to cause no sensible error. Suppose the scantling ABC, plate CXXVII. fig. 12. to be supported in the middle D, by the edge of a triangular block R, and two equal bodies, P, Q, to be suspended at A and C, equally distant from the middle B, of such a weight as to break the scantling. It is evident, that the weights P and Q will cause the scantling to bend at first, so as to make a kind of curvilinear angle at B, and then to break in that place, in a section BD, perpendicular to either of the sides AC; now as the power or force of these weights is more or less, according as they are suspended farther from, or nearer to the fixed point D; these forces will therefore be in proportion to the products of the weights of each multiplied by its respective distance from the section BD; or because the weights and distances are here supposed equal, twice the product of one of the weights P, multiplied by its distance from the section BD, will express the force of these two weights. The force of the weights being thus determined, the resistance or strength of the wood is next to be found, which is done in the following manner. Let $ac b$ (fig. 13.) represent the section of the scantling; it is evident that this area represents the sum of all the fibres to be torn or broken; and as they are all supposed equal, and of the same strength, this area will express the sum of the strength of all the fibres; but as the point D, or the base ab of the section is fixed; and the directions of the fibres perpendicular to the area $ac b$: the force or resistance of each fibre is equal to the product of its strength, multiplied by its distance from the base ab ; and therefore the sum of all the fibres placed in the same line df , parallel to the base ab , multiplied by their distance ad , from that base ab , will express their momentum or resistance. What has been proved in regard to all the fibres placed in the line df , is equally true of all those placed in any other line parallel to the base ab : and therefore the sum of all these products will express the total strength or resistance of the wood: but by the nature of the center of gravity, the product of the area $ac b$, multiplied by the distance of its center of gravity from the base ab , will express the total strength or resistance of all the fibres, or that of the whole scantling; consequently, having the strength of any scantling of the same wood determined by experiment, that of any other may be found.

If the scantling AC (fig. 14.) be supported at both ends by the triangular blocks P Q, and the weight W, hanging in the middle B: then if we suppose the weight P and Q in the first figure, to represent the blocks P and Q in this; then as each block supports half the weight W; it is evident, that the weight W, multiplied by the distance AB or BC, will express its momentum or force. Moreover, since the weight W is suspended in the middle betwixt the fixed points, it is evident that each block supports exactly half the weight; and as the power or force of this weight on the blocks P, Q, is as the product of half the weight multiplied by the distance AB or BC of its direction from the fixed point, it follows, that the whole force of this weight is as twice the product of half the weight W, multiplied by AB or BC; or as the whole weight W multiplied by the distance AB or BC.

Hence also, if the length AC of the scantling between the fixed points A, C, be c , the area of the section s ; the distance of its center of gravity from the base d , and the weight W, w ; then will $\frac{1}{2} c w$ express the force of the weight W, and ds the strength of the scantling: therefore the momentum of the weight is to the momentum of the scantling as $\frac{1}{2} c w$ is to ds ; or, as w is to $\frac{2 ds}{c}$, and if this ratio be given $w = \frac{2 ds}{c}$.

From whence may be drawn several useful consequences. 1. The strengths of two scantlings of the same wood, and of different dimensions; or, which is the same, the weights they will bear, are to each other as the products of their sections multiplied by the distances of the centers of gravity from the base, divided by their lengths. 2. The strengths of two scantlings of the same wood, which have the same length, are as the products of their sections multiplied by the distances of their centers of gravity from the base. 3. The strengths of two scantlings of the same wood, which have equal sections, are as the distances of their centers of gravity divided by their lengths. 4. The strength of scantlings of the same wood, whose distances of their centers of gravity of their sections, from the base, are equal, will be to each other as their sections divided by their lengths.

Again, if the section of the scantling AC be a rectangle placed flat on one of its sides, which we call b , and its height or other side a ; then will ab express the area of the section; and the distance d of its center of gravity from the upper base, will be $\frac{1}{2}a$, therefore the equation already found $w = \frac{2ds}{c}$ becomes here $w =$

$\frac{a^2b}{c}$, which shews that the strength of a rectangular scantling laying flat on one of its sides, is as the product of the square of its height multiplied by its base, and divided by its length. Hence, a deal board of an inch thick, and ten inches broad, being placed on its flat side, and then on its narrow side; the force in the first case, will be to the force in the second as 1 is to 10. For the force in the first case will be as 10 multiplied by the square of unity; and in the second, as unity multiplied by the square of 10; that is, as 10 is to 100, or as unity is to 10. So that if it bears 50 pounds when it lies flat, it will bear 500 when it lies on the narrow side.

TIMBRE, or **TIMMER**, in heraldry, denotes the crest of an armory, or whatever is placed at the top of the escutcheon, to distinguish the degree of nobility, either ecclesiastical or secular.

TIME, *Tempus*, a succession of phenomena in the universe; or a mode of duration, marked by certain periods or measures, chiefly by the motion and revolution of the sun.

The idea of time, in the general, Mr. Locke observes, we acquire by considering any part of infinite duration as set out by periodical measures: the idea of any particular time or length of duration, as a day, an hour, &c. we acquire, first by observing certain appearances at regular, and, seemingly, at equidistant periods.

Now by being able to repeat those lengths or measures of time, as often as we will, we can imagine duration, where nothing really endures or exists; and thus we imagine to-morrow, next year, &c.

Some of the latter school philosophers define time to be the duration of a thing, whose existence is neither without beginning nor end: by which, time is distinguished from eternity.

Time is distinguished into absolute and relative. Absolute time, is time considered in itself, and without any relation to bodies, or their motions. This flows equally, that is, never proceeds faster or slower, but glides on in a constant, equable tenor. Relative time, is the sensible measure of any duration by means of motion. For since that equable flux of time does not affect our senses, nor is any way immediately cognizable thereby, there is a necessity for calling in the help of some nearly equable motion to a sensible measure, whereby we may determine its quantity, by the correspondency of the parts of this with those of that.

Hence, as we judge those times to be equal which pass while a moving body, proceeding with an equable velocity, passes over equal spaces; so we judge those times to be equal which flow while the sun, moon, and other luminaries, perform their revolutions, which, to our senses, are equal.

But since the flux of time cannot be accelerated nor retarded, whereas all bodies move sometimes faster and sometimes slower, and there is, perhaps, no perfectly

equable motion in all nature, it appears hence to follow, that absolute time should be something truly and really distinct from motion. For let us suppose the heavens and stars to have remained without motion from the very creation, does it hence follow, that the course of time would have been at a stand? Or, rather, would not the duration of that quiescent state have been equal to the very time now elapsed?

Astronomical TIME, is that taken purely from the motion of the heavenly bodies without any other regard.

Civil TIME, is the former time accommodated to civil uses, and formed and distinguished into years, months, days, &c.

TIME, in music, is an affection of sound, whereby we denominate it long or short, with regard to its continuance in the same degree of time.

Common or duple time, is of two species. 1. When every bar or measure is equal to a semi-breve, or its value, in any combination of notes of a lesser quantity. 2. When every bar is equal to a minim, or its value, in lesser notes. The movements of this kind of measure are various, but there are three common distinctions; the first slow, the second brisk, and the third very quick. See **CHARACTER**.

TIME, in fencing. There are three kinds of time; that of the sword, that of the foot, and that of the whole body. All the times that are perceived out of their measure, are only to be considered as appeals, or feints, to deceive and amuse the enemy. See **FENCING**.

TIN, *Stannum*, γ , a well-known whitish metal, softer than silver, yet much harder than lead.

Tin is the lightest of all the metals: it is remarkable for a quality that no other of them has, which is, that when bent it makes a crackling noise. It is harder than lead, but less so than any other of the metals: it is malleable in a very remarkable degree, though less so than lead: it may be easily drawn into a coarse wire, but if this be attempted to be brought to any degree of fineness, it snaps and breaks under the workman's hands.

Tin is less susceptible of rust than most of the other metals: it is very little elastic, and scarce at all sonorous. It melts with a much smaller degree of fire than any other metal, a heat but a little greater than boiling-water being sufficient to fuse it. It melts before it grows red-hot, like lead; and a degree of heat so much less even than that requisite to the running of lead, is necessary to the fusing of this metal, that it may be easily separated from the other by eliquation; and if the fire be kept under a mixed mass of the two, so low as to be just hot enough to melt the lead, the tin will all run off from it.

Tin amalgamates very readily with mercury, and may be mixed in fusion with most other metals, and as readily separated from them again by the beforementioned process of eliquation. It is the least simple of all the metals, being brought, by a very small degree of fire, to emit sulphureous fumes: these are plainly the absolute sulphur of the metal. They do great injury to the people employed to work upon it, rendering them pale, and often absolutely destroy them.

The consequence of the emitting these fumes so abundantly is, that tin, of all metals, loses most of its weight, and calcines most easily in the fire. Exposed to the focus of a great burning-glass, it immediately melts, and sends off a large quantity of thick white fume; the remaining matter is then a fine crystalline or glossy matter, in form of needles; these, if held ever so long in the same heat, undergo no farther change, never running into a mass of glass, as the remains of most of the metals do under the same circumstances; but, like the glasses of the other metals, if exposed again to the same heat, laid on a piece of charcoal, they immediately run into tin again; and the same thing happens if it be continued on the tile or coppel it was first placed on in the focus, and some fat matter, as tallow, or the like, be added to it.

Filings of tin thrown into the flame of a candle, take fire, and render the flame blue, emitting a visible fume and a smell of garlic: melted in a crucible, with a mixture of nitre, it deflagrates. Its constituent matters, therefore, seem to be a crystalline earth which melts with

with great difficulty, and an inflammable sulphur; in which, from its smell, while calcining, and from its poisonous quality, it is probable there may be something of arsenic mixed.

Tin so far endures the force of lead and antimony in the refiner's test, that it is hardly to be separated from them, unless by the addition of copper: it adheres to the rest of the metals with greater ease than any other, and hence it is in continual use in covering plates of iron, and lining copper, and other metals, to prevent their rusting, and to save the liquids put into them from taking up any bad qualities from those metals, as it is much more difficultly dissolved by common menstrooms, than either of them. Tin, in many things, greatly approaches to the nature of silver. It very readily melts with silver, gold, or copper; when the mixture is made with equal, or even a less quantity, it renders them extremely brittle; but it is very singular, that if it be mixed in a much larger quantity, they still continue pliant and flexible. Ten parts of tin, and one of copper, make a mass more rigid indeed than tin, yet malleable and ductile. Silver, of all metals, suffers most by an admixture of tin, a very small quantity of it serving to make that metal as brittle as glass; and what is worse, being very difficultly separated from it again. The addition of about one tenth part of copper to tin makes it fit for the common uses of life, in vessels of various kinds, as it becomes, by the mixture, more durable; a little zink, added to this mixture, gives the metal a yellow colour; and, as it is mixed in greater or less quantity, makes it fit for casting of cannon and for bells.

Iron readily mixes with tin, in fusion, if the fire be brisk, and the iron be heated white hot before the tin be added. Twice the quantity of this metal, added to iron so heated, readily runs with it into an odd substance, which is very white and brittle, and readily answers to the magnet. This has been used, by some, as a pretence of its not being iron, and that the loadstone would attract another metal beside that; but the fallacy is easily discovered by any one that understands any thing of metallurgic analysis.

Lead bears a considerable admixture of tin, without being affected as gold and silver are, which are both rendered brittle by it; at least, its effects on this metal are in a much smaller degree. The very vapour of tin has the same effect with the metal itself on silver, gold, and copper, rendering them brittle. Many a metallurgist has been long plagued by these vapours by a piece of tin being accidentally among his charcoal; the consequence of which has been, that, till it was burned wholly away, these metals have been rendered as brittle as glass under the hammer, by only being fused over these coals. It is owing to this property of tin, in making the metals it is mixed with brittle, that it renders them sonorous. Mr. Boyle has expressed a wonder that tin, which is itself not much sonorous, should on mixture with copper render it more so; but if we consider that the same sort of disposition of parts which renders metals rigid and brittle renders them sonorous, the mystery is explained.

The proper solvent of tin, in its true malleable state, is aqua regia. It will not well dissolve in any of the other menstrooms of the stronger kinds, nor indeed very readily in this. We are not, however, to wonder at this difficulty of solution in tin, since we find it contains much more sulphur than any other metal, and sulphur is not one of those substances that are to be dissolved by acids. That this is a fact, we find by putting calcined tin, instead of common malleable tin, into the menstrum; for in this case even vinegar will dissolve it. While tin is in its malleable state, the weakest acids dissolve it best. Verjuice, and it is said even four apples boiled in tin vessels, acquire a taste of that metal, though the strongest acids, aqua regia excepted, boiled in the same vessels, acquire no flavour from it at all.

Many of the chemical writers have been of opinion, that, if the sulphur could be thoroughly purged from tin, it would be no longer tin, but silver; it is certain that the two metals have many things in common. If dissolved in aqua regia, tin is bitter, as well as silver, in solution with the nitrous acid; but the crystals which are produced from a solution of it in vinegar, after it

has been calcined for forty-eight hours together, which is a necessary step towards such a solution, and which one would think should bring it nearer to silver than before, if the dissipating its sulphur were the way to do it, differ wholly from those of silver. We have indeed accounts, in many authors, of tin being made to yield a large quantity of silver by peculiar processes; but that careful experimenter Mr. Boyle tells us, that all tin is not to be expected to yield those advantages in the same manner; for that himself had separated pure crystals of silver from one parcel of tin by a peculiar menstruum, but that another parcel of the same metal would not answer in the same manner.

Though tin and lead readily unite in fusion over a gentle fire, if the heat be afterwards raised to a violent degree, there is a visible motion excited in the mixture; and the consequence is, that both are reduced to a calx, and the lead becomes extremely difficult afterwards to vitrify.

The effect that zink has upon a mixture of tin and copper, the copper being in a larger proportion than has been usually given in such mixtures, is little known, and seems to be a secret that the people who are possessed of it intend to make use of to themselves.

Tin, when it mixes itself with crystal in the earth, influences both its figure and colour. It gives it a pyramidal form consisting of four sides, short and with a broad base, and at the same time usually communicates a yellow colour with an admixture of a dusky brown, which makes it much inferior to the yellow crystal made so by lead. Even the tin-grains, though very different substances from the crystals we are describing, have something of this yellow colour, which appears when they are broke into small pieces, though in the mass they are opaque and blackish. In the making of the artificial gems, there is a method of obtaining this colour from tin, and communicating it to glasses. It seldom succeeds indeed in the common way of doing this by lead: but in vitrifications, where the basis is borax, the calx of tin properly treated with vinegar yields crystals, which will communicate the true colour of the browner topazes to the vitrified mass.

The ores of tin are very various, as it is found blended with all kinds of substances, with marcasitic and stony matter, and even with other metals. The Germans have lately talked of finding native tin in the perpendicular fissures of some of their iron mines; but there seems no foundation for the opinion; for this pretended native tin wants the first of all the characters of a native metal, malleability. It flies to pieces under the hammer, and on trial in the fire proves to be a marcasitic ore, very rich indeed in tin, a very singular and valuable substance, but not, as pretended, native tin. This remarkable ore is found in nodules from an ounce to three or four in weight; it is of a bright silvery colour, like the white arsenical pyritæ, but covered with a coarse dusky crust: when properly worked, it is the richest tin-ore to be met with, five drachms of pure tin having been separated from an ounce of it.

The next ore to this in richness, and that which has consequently been usually accounted the richest of all, is the tin-grain, or lapis jovius. This is an ore of tin, of a fine glossy black colour on the out-side, but, in thin pieces held up against the light, it is transparent and yellowish: it is the heaviest of all the metalline ores, and is of a very irregular figure, but in the finest pieces it seems to approach to the shape of those crystals which are found joined base to base, without any intermediate column. In size it is of the bigness of a large walnut down to that of a pin's head; for of that minuteness we meet with some perfect tin-grains.

After the tin-grain we shall mention a black and very heavy tin ore, of an irregular figure and metalline appearance; but this, though it promises very fairly by its weight, seldom yields so much as half a drachm of metal from the ounce, in its crude state; if washed indeed, and all the foreign matter carried off, it may be reduced almost to the purity of the tin-grains before the working.

The tin-ores of Germany usually contain a very large quantity of iron; ours are free from this admixture, and are greatly the more valued for it. Our other ores of tin,

tin, besides the two above described, are a brownish or blackish stony one, very hard and heavy; this is debased by a great quantity of the stony matter, and requires careful washing before it is brought to the fire; and a yellowish or whitish ore, which are less heavy and more brittle than the others, and contain a large quantity of common sulphur; and to these may be added another, in which the metal is yet more mixed with sulphur: this is the mundic found in the tin-mines, which is very bright and shining, of a silver or gold colour, and often contains a large portion of tin, though it is not separated from it without difficulty, because of the abundance of sulphur in the mass. We have also red ore of tin, of a stony, and sometimes of an earthy nature, and carrying so little of the appearance of an ore of this metal, that it is hard to guess what could lead any body to work it in expectation of it. It is however very rich.

Tin ore is also sometimes found mixed with that of lead, and carrying the external appearance of lead only. Some of these ores are neglected in France, where they might turn to a very considerable account under proper management. The German ores of tin are usually so much like iron, that, at first sight, it is scarce possible to distinguish them. We are also finally to add to the number of tin ores the dodecahedral garnets sold by our druggists; these are in general irregularly figured, but the most regular of them always consists of twelve sides; they are of a deep red colour, and in size from the bigness of the largest pea to that of a pin's head. These are truly ores of tin, of the nature of the tin-grains, but not so rich.

There is something very singular in the great gravity of tin-ore beyond that of the ores of other metals; but it contains so much arsenic, and is so dangerous to the person who works it, that experiments are not expected to be made very frequently on it.

The tin ores in general are stubborn and refractory in the fire; it is easy, however, to find whether an ore does contain this metal or not; for, if a piece of it be powdered and washed, and afterwards sprinkled thinly over an iron-plate made white hot on the fire, the tin ore, in this case, if there be any in the mass, will be found in little parcels of a red colour covered with grey flowers of an arsenical smell. The various kinds of mundic common in the Cornish mines are not only rejected from the works as ores themselves, but they are carefully separated from among the other ores of a better kind, as they are apt to be very troublesome, even in the smallest quantities, in working the rest. They then pound and wash the ore; and when they have thus separated all the lighter impurities, till there is no longer any smell of sulphur or of garlic, they grind it to a tolerable fine powder, and, after washing it again, it is carried to the melting-houses, where it is melted into metal by mixing it with charcoal, and urging the fire to the utmost violence by the blast of large bellows. There is a cavity at the bottom of the furnace into which the metal runs, as it separates from the ore, and out of which they let it by an aperture closed and opened at pleasure, running it in cakes or pigs, which are the large blocks we see it in.

Tin ore, in general, contains a great quantity of arsenic, which discovers itself in the roasting in form of a white cloud, and which it is very material to burn quite away, as it otherwise renders the metal brittle. Charcoal alone commonly serves for fluxing the ore of tin, but, if any be found refractory, a little common black pitch is an excellent addition.

The virtues of tin, as a medicine, given internally, have been celebrated by many of the ancient writers, but it has less credit at present. We have been told that in diseases of the lungs, and in disorders of the head and uterus, there is scarce any thing equal to it; and that in convulsions, epilepsies, and the madness arising from the bite of a mad-dog, it was a certain remedy. These last are the only cases in which it has any degree of credit at present, and that is rather among the vulgar than among physicians.

In the manufactures it is of great use in solders, and when amalgamated with mercury, and a little bismuth added to make it run thin, it serves in the silvering of

looking-glasses. By calcination it makes a soft powder called putty, of great use in polishing glass and gems, and also in making enamels.

The preparations of tin are, 1. Powdered tin, made by pouring melted tin into a wooden box, the inside of which is chalked all over, and briskly shaking it till cold, when a part of it will be found reduced to powder, which is said to be good for worms, but we have no certain accounts of its good effects. 2. Salt of tin, obtained by pouring distilled vinegar upon calcined tin, heating the solution till it near boils, and afterwards evaporating it to a pellicle, and setting it in a cool place; then there will shoot very pellucid and hard crystals, which are recommended in hysteric cases, to be given from two to four or five grains at a dose. 3. The antihæctic of Poterius. 4. The aurum musivum, or, as it is commonly called, mosaicum, mosaic gold.

To these preparations used in medicine, we may add one well known as a cosmetic: it is a magistery of tin prepared in the manner of that of bismuth, by first mixing six ounces of spirit of nitre with one ounce of spirit of sea-salt, and then putting tin into this liquor, or aqua regia, till it is capable of holding no more; lastly, pour the solution into six or eight quarts of spring water, and the tin will be precipitated in form of a white powder, which should be washed several times, and then dried for the use of the ladies in pomatums, to render the skin white and soft.

TIN-FLOORS, a contrivance used by our husbandmen who propagate hops to dry them after the gathering. The common way of doing this is either on a hair-cloth on a malt-kiln, or else by the oost. See the articles Hops and Oost.

In both these ways, however, the hops suffer very much; the best way is by the tin-floor. It is thus done: let a square brick room be built, with a door on one side, and a long fire-place of a foot wide in the middle, reaching almost across it; let holes be made at the sides of this fire-place, to let out the heat into the room; and, at the height of five feet above this, let a floor be made of laths of an inch thick, laid lattice-wise. Let this be covered with great plates of double tin, taking care that the joinings of the tin be well soldered, and lie upon the laths, not over the interstices, which may be about four inches wide. Let a row of boards be fitted round the edge of this floor, to keep the hops from falling off; then lay on a covering of hops of a foot thick; then make a small fire of charcoal in the mouth of the fire-place, and the hops will dry very quick and very regularly. They may be continually stirred about while drying, and, when enough, a part of the boarded edge of the kiln may be taken down, and the dried parcel thrust out, and a fresh parcel laid on in their place. A very small quantity of fuel is sufficient in this way, and any fuel will do, for the smoke never comes at the hops.

There is a very great improvement still upon this method of drying hops, used by some people; this is the making a wooden cover, of the size of the tin-floor; this is covered with plates of tin nailed on, and is suspended over the kiln in such a manner, that it may be let down at pleasure, when the lower parts of the hops are dry. This is to be let down within ten inches of their surface, and there acts as a reverberatory, and drives back the heat on the upper ones: thus all the trouble of turning is saved, and the hops are much better dried than in any other way. *Mortimer's Husbandry.*

TIN-HATCH, in mining, a term used by the people of Cornwall, to express the opening into a tin-mine. They also call it a tin-shaft.

They make several openings in the sides of the hills where they suspect veins of ore to be. All these, except that which opens on the head of the mine, are called essay-hatches; but that which does so, is made their entrance afterwards, and changes its name to that of the tin-hatch.

TIN PLATES, an article of manufacture very common among us, and vulgarly called tin. It is iron plated over with tin. The French call it *fer blanc*, white iron; as we do sometimes in England. It was

once known under the distinct name of latten. See the article LATTEN.

TINCTURE, *Tinctura*, in pharmacy and chemistry, a separation of the finer and more volatile parts of a mixed body, made by means of a proper menstruum dissolving and retaining the same.

The management and rules of procedure in tinctures, elixirs, medicated wines, vinegars, decoctions, and infusions, depend upon the same reason and principles; these several forms differing only in the fitness of the materials for suspension, in fluids of different consistencies, and the best manner thence arising for drawing them out: the principal rule in all which is, that the liquor, made use of for a menstruum, or vehicle, be more or less spirituous, as the ingredients, which are ordered in it, are of a lighter or more fixed nature; and the times of standing in digestion, either hot or cold, are also to be proportioned accordingly.

A general rule for the properly making light tinctures may be taken from the following bitter: take half an ounce of Seville orange-peel shaved thin, half a dram of gentian root thin sliced, a scruple of the tops of Roman wormwood, half a dram of cardamom seeds, and the same quantity of cochineal, each of them lightly bruised; put these ingredients into a pint of French brandy, let them steep for one night, and filter the liquor the next morning, and thus you have a fine light bitter.

These bitters are of the number of many other substances, where the goodness of a tincture does not more depend upon the choice of the ingredients, than upon the manner of their being infused; for, if such be suffered to remain too long in the menstruum, or, if heat be used in extracting the tincture, the gross terrestrial and nauseous parts of the ingredients will be fetched out, and the tincture will thus be loaded with a heavy indolent matter of little virtue. *Shaw's Lectures*.

A great variety of tinctures may be given to common water, and many remarkable things occur in their changes on the addition of common menstrua: take a large spoonful of the syrup of pomegranate-flowers, mix it with five spoonfuls of water; the mixture will be of a very lively and brilliant red: for a violet colour, take the same quantity of syrup of violets, and the same of water. When the tinctures are thus prepared, have at hand a phial in which is a small portion of oil of tartar, which will only look like water remaining after the washing of the phial.

Pour the red or the violet tincture into this phial, and it immediately becomes a fine grass-green. Dissolve the quantity of a walnut of crude sal armoniac in a glass of water, pour all out except three or four drops at the bottom, and pour into this glass the fine red liquor, and it immediately becomes black as ink. In order to change the purple liquor red, only have a small quantity of spirit of vitriol in the bottom of a phial, and pour it into this; the violet water, immediately on this, becomes of a florid red.

Steep Brasil wood in common water, or in white wine twenty hours; the liquor will then look of the colour of red wine; pour this into a glass washed with vinegar, and it becomes of a fine yellow like sack. If this experiment be made with white wine, the wood and the vinegar make so little alteration in it, that it may be drank afterwards, and the whole process seems a way of turning red port into sack. Into this liquor when yellow, drop a few drops of a tincture of benjamin made in spirit of wine, and it immediately loses its yellow colour and becomes white. Beat some galls to fine powder, and rub the powder on a towel; then put into a basin of water, in which any person is going to wash their hands and face, a small piece of common green vitriol, or copperas; after the person has washed, let them have this towel to wipe on, and the hands and face will be as black as if washed with common writing-ink; the copperas in the water and the galls on the towel making real ink where they mix. This does no lasting injury to the skin, but will come off again upon washing with soap. *Philos. Transf.* N°. 238.

TINCTURE of Antimony, *Tinctura Antimonii*, is thus made. Take salt of tartar a pound, antimony half a pound,

rectified spirit of wine a quart; reduce the antimony to a powder, and mix it with the salt by fusion over a strong fire. When it is cold, powder it, and pour on the spirit of wine; digest them together three or four days in a sand heat, and then filter off the clear tincture for use. The salt of tartar yields a tincture as well as the antimony.

TINCTURA Foetida, the stinking tincture, a form of medicine in the late London Dispensatory prepared in this manner: take assa-fœtida four ounces, rectified spirit of wine a quart, digest them together for some time, and then strain off and filter the tincture through paper.

TINCTURA Sacra, a tincture of aloes, called also hiera picra. The late London Dispensatory has ordered this to be made of only eight ounces of aloes, and two ounces of winter's bark powdered, and put into five quarts of white-wine, which is to be shook often, and kept in fusion a week or more without heat, and then strained off for use.

TINCTURA Saturnina, the lead tincture, a name given in the late London Dispensatory to the tincture before called *tinctura antiphthifica*.

It is made of sugar of lead and green vitriol, each two ounces; of rectified spirit a quart. The salts are separately to be reduced to powder, and then put into the spirit; then the whole is to stand some days without heat to extract the tincture, and afterwards filtered through paper.

TINCTURA Senæ, a form of medicine prescribed in the new London Pharmacopœia, and intended to stand in the place of the medicine commonly called elixir salutis, and Daffy's elixir. It is thus made: take stoned raisins sixteen ounces, leaves of sena a pound, caraway seeds an ounce and half, cardamom-seeds half an ounce, proof spirit a gallon; digest all together without heat, and, when the tincture is well extracted, press off the spirit, and filter it for use.

TINCTURA Styptica, a form of medicine made with very little trouble and apparatus, and serving to supply the place of that elaborate preparation the tincture of Helvetius; it is prescribed in the late London Pharmacopœia, and is to be made by mixing a drachm of calcined green vitriol with a quart of French brandy, tintured by the cask; this is to be shook together that the brandy may turn black, and then strained off for use. *Pemb. Lond. Dispens.*

TINCTURE is also applied by the heralds, to the colour used in escutcheons, or coats of arms; under which may be likewise reduced the two metals, or and argent, because often represented by yellow and white.

TINEA, in medicine, a disease, the same with the achor or crusta lactea. See ACHOR.

TIN-GLASS, a name given by some to a mineral water more commonly called bismuth. See BISMUTH.

TINGING of Marble. The art of doing this has, in several persons hands, been a very lucrative secret, tho' there is scarce any thing in it that has not at one time or other been published. Kircher has the honour of being one of the first, who published any thing practicable about it. This author meeting with stones in some cabinets supposed to be natural, but having figures too nice and particular, to be supposed of nature's making, and these not only on the surface, but sunk through the whole body of the stones, was at the pains of finding out the artist who did the business; and on his refusing to part with the secret on any terms, this author, with Albert Gunter, a Saxon, endeavoured to find it out; in which they succeeded at length very well. The method is this: Take aqua fortis and aqua regia of each two ounces, sal armoniac one ounce, spirit of wine two drams, about twenty-six grains of gold, and two drams of pure silver; let the silver be calcined and put into a vial, and pour upon it the aqua fortis; let this stand some time, then evaporate it, and the remainder will first appear of a blue and afterwards of a black colour. Then put the gold into another vial, pour the aqua regia upon it, and when it is dissolved, evaporate it as the former. Then put the spirit of wine upon the sal armoniac, and let it be evaporated in the same manner. All the remainders, and many others made in the same manner from other metals, dissolved in their proper acid menstrua, are to be kept separate, and used

used with a pencil on the marble. These will penetrate without the least assistance of heat, and the figure being traced with a pencil on the marble, the several parts are to be touched over with the proper colours, and this renewed daily till the colours have penetrated to the desired depth into the stone. After this, the mass may be cut into thin plates, and every one of them will have the figure exactly represented on both surfaces, the colours never spreading. The nicest method of applying these, or the other tinging substances, to marble, that is to be wrought into any ornamental works, and where the back is not exposed to view, is to apply the colours behind, and renew them so often till the figure is sufficiently seen through the surface on the front, though it does not quite extend to it. This is the method that, of all others, brings the stone to a nearer resemblance of natural veins of this kind.

TINNING, the covering or lining any thing with melted tin, or with tin reduced to a very fine leaf. Looking-glasses are foliated, or tinned with thin plates of beaten tin, the whole bigness of the glass, applied or fastened thereto by means of quicksilver.

TINNITUS AURIUM, a noise or buzzing in the ear, when it receives sounds which do not exist, or at least which are not produced by the motion of the external air; and the ear being filled with a certain species of sound, cannot admit other sounds, unless they are very violent. The tinnitus is of two kinds, the one proceeding from a distemperature of the organ of hearing, the other from a disorder of the brain.

The cure, according to Heister, is to be performed by temperate diaphoretic powders, and resolving essences, commonly called anticatarrhals; as of amber, the woods, rosemary, together with diaphoretics and alexipharmics, taken often in a day, with tea of betony, with rosemary-flowers, sage, or lavender, or saffras. In the morning, and at noon, the essences are to be taken, and at night the powders. Essence of amber may be applied outwardly, either alone or with a few drops of oil of amber, or one or two drops of oil of camomile put into the ear with cotton, morning and evening; or a grain or two of amber and musk, or castor, in cotton, either alone or with Peruvian balsam; or carminative oils, such as anise, fennel, carraways, or camomile; not neglecting pediluvia, and frequent rubbing of the feet and head. Many have also been cured by the vapour of a decoction of lavender-flowers, or rosemary, made with wine, being conveyed to the ear with a funnel. If the disease is obstinate and inveterate, the patient must bleed in the foot, together with scarifications, and frequent purges, for the sake of revulsion. Etmuller says, this noise proceeding from burning fevers, will go away of itself; but if it proceeds from chronic disorders, it is difficult of cure. However, he recommends vapours of southern-wood, wormwood, origanum, eyebright, balm, &c. as also of amber, or gum ammoniac; likewise oil of peach kernels, and spirit of wine, put into the ear with cotton.

The following formula is greatly praised. White hellebore and castor, take of each two drams; of costmary, one dram and a half; of rue, two drams; euphorbium, half a dram; of bitter almonds, two drams and a half: let them be boiled in the oil of rue, and poured warm into the ear. Shaw recommends half an ounce of oil of bitter almonds, with two drams of oil of castor, externally applied.

TIPSTAFF, an officer who attends the judges with a kind of staff tipped with silver, and takes into his charge all prisoners who are committed or turned over at a judge's chambers.

TIRE, or **TEER** of *Guns*, in the sea-language, is a row of cannon placed along a ship's side, either above, upon deck, or below, distinguished by the epithets of upper and lower tires.

TITANS, in the heathen mythology, the offspring of Titan, the elder brother of Saturn, upon whom, and his son Jupiter, they made war, in order to recover the sovereignty of which Titan had been deprived. The poets represent them as a race of giants, sprung from the earth, and invading heaven; and tell us, that Jupiter

overcame them with thunder, and drove them down to the very bottom of hell.

TITHES, *Decimæ*, in law, denote the tenth part of the increase that annually arises from the profits of lands, and the industry of the parishioners, which is payable for the maintenance of the parson of the parish.

Tithes, it is observed, are of three kinds, predial, personal, and mixed. Predial tithes are such as immediately arise from the land, whether it be by manuring, or its own nature; as corn, grain, hay, wood, fruit, and herbs, which are said to be due without the deducting the costs. Personal tithes are those which only arise from a person's labour and industry, they being a tenth part of his gains in trade, &c. after charges deducted; but this is seldom paid in England, and when it is, it is always due by custom, and payable where the party dwells, hears divine service, &c. Mixed tithes are such as arise not directly from the ground, but from cattle and other things that receive their nourishment from, and are maintained thereout; as calves, colts, pigs, wool, lambs, milk, &c. Tithes are further divided into great and small; great, are corn, hay, and wood; small comprehend all other predial tithes besides corn, &c. as likewise such tithes as are personal and mixed: the great tithes generally belong to the rector, and the small to the vicar.

It has been held, that where land is barren, and not manurable without extraordinary charge, such land being converted into tillage, shall, for the first seven years after the improvement, be free from paying tithes; but during that space of time it shall pay such small tithes, as have been usually paid before, and afterwards the full tithe, according as it is improved: nevertheless, if land is suffered to be over-run with bushes, or become unprofitable through want of husbandry, in that case it cannot properly be called barren; and if the same be grubbed up, or ploughed and sowed, it immediately pays tithes.

As to corn it is tithed by the tenth cock, or sheaf, which if the owner does not set out, he is liable to an action upon the statute; likewise where a parishioner will not sow the land, the parson may bring his action against him. On the other hand, when the tithes are set forth, if the parson do not carry them away in a reasonable time, but lets the same be too long on the ground, to the prejudice thereof, he may be also subject to an action.

The treble damages, granted by statute, are recoverable in the temporal courts by action of debt, those damages not being limited where to be recovered; and it is the opinion of some, that the double value, or damages, above-mentioned may be recovered in the spiritual court, for this reason, that the person grieved may sue in the ecclesiastical-court for the tithes themselves, or a recompence in lieu of the same, and may also at the same time have the double value. Small tithes that are under the value of forty shillings, a parson may recover before two justices of peace, who are no way interested in the tithes, within twenty days after demand, and two years after due: and the justices may, by distress, levy the money by them adjudged, upon the party's refusal to pay it, ten days after notice, &c. The justices may likewise award costs not above ten shillings, but with liberty to appeal to the quarter-sessions, whose judgment shall be final, unless the title to such tithes shall come in question, &c.

Where a quaker refuses either to pay or compound for great or small tithes, the two next justices of the peace may, on complaint thereof made, summon such quaker before them, and after examining the matter of complaint on oath, may, by order under their hands and seals, direct the payment in all cases under ten pounds. And if, after such order made, the quaker refuses to comply therewith, any one of the justices may by warrant order the same to be levied by distress, &c. See 7 and 8 Wil. III. c. 34. which, by 1 Geo. I. c. 6. is made perpetual.

Notwithstanding these acts, tithes, if of any considerable value, are generally sued for in the exchequer by English bill, except where the suit is founded on the

statute

statute of 2 and 3 Ed. VI. for double or treble value, &c.

The custom of giving or paying tithe is very ancient: in Gen. xiv. 20. Abraham gives Abimelech the tenth of all the spoils he had taken from the four kings he had defeated: in Gen. xxviii. 22. Jacob makes a vow, at Bethel, to give the tenth of all the riches he shall gather, in that sojourn, to God.

But these tithes were free and voluntary; and, besides, differed in divers other respects from what was afterwards called tithe: what Melchisedec received, was only the tenth of the spoils, not of Abraham's possessions; and this once, not annually; and besides, not as maintenance, which Melchisedec wanted not, but as homage: add, that this was only from one priest to another; for Abraham had not only a priest in his loins, but was a priest himself. — And as to Jacob, who was also a priest, what he did was the effect of a vow, voluntarily taken, to offer the tenth of all he should possess; not to any other priest, but to God himself upon an altar.

Under the new law, it is not Jesus Christ that established tithes, as it was God himself did it under the old law by the ministry of Moses; the Christian priests, and the ministers of the altar of the new covenant, lived, at first, wholly on the alms and oblations of the devout.

In after times the laity gave a certain portion of their revenues to the clergy, but voluntarily, and not out of any constraint or obligation: the first instances we have of it, are in the IVth and Vth centuries.

This gift was called tithe; not that it was really a tenth part of their income, or near so much: but only in imitation of the tithes of the old law.

In the following age, the prelates in their councils, in concert with the princes, made an express law to the purpose; and obliged the laity to give a full tenth part of their revenues, their fruits, &c. to the ecclesiastics.

This the church enjoyed without disturbance for two or three centuries; but in the VIIIth century the laity got hold of part of these tithes, either by their own authority, or by grants and donations of the princes; and appropriated them to their own uses.

Some time afterwards they restored them, or applied them to the founding of monasteries or chapters; and the church consented, at least tacitly, to this restitution.

In 1179, the third council of Lateran, held under Alexander III. commanded the laymen to restore all the tithes they yet held to the church.

In 1215, the fourth council of Lateran, held under Innocent III. moderated the matter a little; and, without saying any thing of the tithes which the laity already possessed, forbade them to appropriate or take any more for the future.

Fra. Paolo, in his treatise of Beneficiary Matters, is of opinion, that the custom of paying tithes under the new law began in France; and affirms, that there are no instances of it before the VIIIth and IXth centuries: but he must be mistaken; for in the second council of Matiscona, held in 585, it is said expressly, that the Christians had a long time kept inviolate that law of God, whereby tithe of all their fruits was enjoined to be given to holy places, &c.

In effect, Origen, Hom. XI. on Numbers, thinks, that the old laws of Moses, touching the first fruits and tithes both of cattle and of the fruits of the earth, are not abrogated by the gospel; but ought to be observed on their ancient footing. The Vth canon of the council of Matiscona orders tithe to be paid to the ministers of the church according to the law of God, and the immemorial custom of the Christians, and that upon penalty of excommunication: which is the first penalty we find imposed on such as would not pay tithe. — On which grounds it is that many among the modern clergy hold their tithes to be *jure divino*.

Others, on the contrary, plead, that the recompence to be given church ministers, is differently ordained by God, according to the differences he has put between his two great dispensations, the law and the gospel: under the law he gave them tithes; under the gospel, having

left all things in his church to charity and Christian freedom, he has given them only what shall be given them freely, and in charity. That the law of tithes is in force under the gospel, all the protestant divines, except some among the English, deny; for though hire to the labourer be of moral and perpetual right, yet that special kind of hire, the tenth, can be of no right or necessity, but to the special labour for which God ordained it: that special labour was the levitical and ceremonial service of the tabernacle, Numb. xviii. 21, 31. which was abolished: the right therefore of the special hire must be abolished too.

That tithes were ceremonial, is evident from their not being given to the Levites till they had been first offered as a heave-offering to the Lord, ver. 24, 28.

He, then, who by the law brings tithes into the gospel, brings in likewise a sacrifice, and an altar; without which, tithes, by the law, were un sanctified and polluted, ver. 32. and therefore were never thought of in the first Christian times, till ceremonial altars and oblations had been brought back.

The Jews themselves; ever since their temple was destroyed, tho' they have rabbies and teachers of the law, yet pay no tithes, as having no proper Levites to whom, nor altar whereupon, to hallow them; which argues, that the Jews themselves never looked on tithes as moral, but merely ceremonial. Add, that tithes were not allowed to the priests and Levites merely for their labour in the tabernacle, but in consideration of this likewise, that they were not allowed to have any other part or inheritance in the land, ver. 20, 24. and who, by that means, for a tenth, lost a twelfth.

In effect, for the first three hundred years after Christ, no mention is made in all ecclesiastical history of any such thing as tithes; though, in that time, altars and oblations had been recalled, and the church had miserably judaised in many other things. The churchmen confessedly lived all that time on free-will-offerings; nor could the defect of paying tithe be owing to this, that there were wanting civil magistrates to enjoin it; since Christians, having lands, might have given out of them what they pleased: and the first Christian emperors, who did all things by advice of the bishops, supplied what was wanting to the clergy, not out of tithes, which were never proposed, but out of their own imperial revenues. The first authority produced, setting aside the apostolical constitutions, which few of the patrons of tithes will insist on, is a provincial synod at Cullen in 356, where tithes are voted to be God's rent; but, before that time, divers other abuses and complaints had got ground, as altars, candles at noon, &c. And one complaint begot another; as it is certain that tithes suppose altars.

It is alleged, that tithes are of early and solemn force among us, having been paid by statute ever since the Saxon king Athelstan, anno 928: to which it may be answered, that Rome scot, or Peter-pence, had been likewise paid to the pope by statute above 200 years longer, viz. from the year 725. And it is also to be observed, that these ancient tithes, among our ancestors, kept a nearer analogy to their original in the Mosaic law; for the priests had but a third part, the other two thirds being appointed for the poor, and to adorn and repair the churches, as appears from the canons of Ecbert and Elfric.

TITLE, *Titulus*, an appellation of dignity, or quality, given to princes, and other persons of distinction. Thus, the title of his Britannic majesty, is king of Great Britain, France, and Ireland; that of the French king, is king of France and Navarre: and so of others. The pope assumes the title of holiness, and the cardinals that of eminence, &c.

TITLE, in law, denotes any right which a person has to the possession of a thing; or an authentic instrument, whereby he can prove his right.

As to the titles of the clergy, they denote certain places wherein they may exercise their functions. There are several reasons why a church is called *Titulus*; but that which seems to be the best, is because anciently the name of the saint to whom the church was dedicated, was engraved on the porch, as a sign that the saint had a title to that church; and from thence the church itself was

afterwards called Titulus. In this sense a title signifies the church to which a clergyman was admitted, and where he is constantly to reside: and by the canons none shall be ordained without a title. This is in order to keep out such from the ministry who, for want of maintenance, might bring a disgrace upon the church: can. 31. In short, according to some writers, such a title is an assurance of being preferred to an ecclesiastical benefice; that is to say, a certificate that the clerk is provided of some church or place, or where the bishop that ordains him, intends shortly to admit him to a benefice or curacy then void.

TITMOUSE, *Parus*, in ornithology, a genus of birds, the beak of which is of a subulated form, and the point of the tongue truncated.

Of this genus there are many elegant species, among which the crested and blue titmouse are not the least beautiful.

TITUBATION, or **TREPIDATION**, a kind of libration, or shaking, which the antient astronomers attributed to the crystalline heavens, in order to account for certain irregularities which they observed in the motions of the planets.

TITULAR denotes a person invested with a title, in virtue of which he holds an office or benefice, whether he perform the functions thereof or not.

The appellation of titular is frequently also given to a person who has the title and right of an office or benefice, but without having possession, or discharging the functions thereof.

TMESIS, *ῥυσις*, in grammar, a figure whereby a compound word is separated into two parts, and one or more words placed between them: thus, for *quæcunque*, Virgil says, *quæ me cunque vocant terræ*, &c.

TOAD, *Rubeta*, in zoology, belongs to the same genus with the common frog. See **FROG**.

The toad is larger than the frog, with a thick body, a broad back, and the belly swelled and inflated: its skin is considerably thick, and full of tubercles, of a dusky and blackish colour on the back, and spotted on the belly: it is naturally a loathsome and disagreeable object.

TOBACCO, *Nicotiana*, in botany, a genus of plants, whose flower is monopetalous and funnel-shaped; the tube is longer than the cup; and the limb, which spreads open, is divided into five acute-pointed segments; the stamina consists of five subulated filaments, topped with oblong antheræ; the fruit is an oval capsule, with a furrow on both sides, opening at the top in two cells, which contain a great many rough kidney-shaped seeds.

There are several species of tobacco; the flowers of some are less acute-pointed than others; they are all natives of America, and brought originally from thence, and at first were in great esteem for their medicinal qualities.

This plant was not known in Europe, till after the discovery of America by the Spaniards: The Americans on the continent call it petum, and those of the islands yoli.

It was first brought into Europe by M. Nicot, from the island Tobago, in America, about the year 1560, whence its English name; and is now cultivated for medicinal use in our gardens. It is perennial, as is said, in America; and annual with us.

Tobacco is cultivated in several parts of America, particularly in the Caribbee Islands, Virginia, &c. where they are forced to mix ashes with the soil, to prevent its rising too thick. After sowing, they water it every day; and on very hot days cover it up, to prevent its being scorched by the sun.

When the plants are grown to a convenient pitch, they are transplanted into a soil well prepared for their reception: care is also taken to keep this ground clear of weeds, and to pull off the lowest leaves of the plant, that ten or fifteen of the finest leaves may have all the nourishment. When these leaves are ripe, which is known by their breaking when bent, the stalks are cut, and left to dry two or three hours in the sun; after which they are tied together two and two, and hung on ropes under a shed to be dried by the air. And when

the leaves are sufficiently dried, they are pulled from off the stalks, and made up in little bundles; which being steeped in sea-water, or, for want thereof, in common water, are twisted in manner of ropes, and the twists formed into rolls, by winding them with a kind of mill around a stick: in which condition it is imported into Europe, where it is cut by the tobaccoists for smoking, formed into snuff, and the like.

Besides the tobacco of the West-Indies, there are considerable quantities cultivated in the Levant, the coasts of Greece and the Archipelago, the island of Malta and Italy.

The marks of good twist-tobacco, are a fine shining cut, an agreeable smell, and that it have been well kept. Tobacco is either taken by way of snuff, as a sternutatory, or as a masticatory, by chewing it in the mouth, or by smoking it in a pipe. It is sometimes also taken in little longish pellets put up the nose, where it is found to produce very good effects, to attract a deal of water or puita, unload the head, resolve catarrhs, and make a free respiration; for the subtle parts of the tobacco in inspiration, are carried into the trachea and lungs, where they loosen the peccant humours adhering thereto, and promote expectoration. Some have left this tobacco in their noses all night; but this is found to occasion vomiting the next morning. Another thing charged on this way of application, is, that it weakens the sight. When taken in great quantities in the way of snuff, it is found to prejudice the smelling, greatly diminishes the appetite, and in time gives rise to a phthisis. That taken in the way of smook, dries and damages the brain. Borghi, in a letter to Bartholine, mentions a person who, through excess of smoking, had dried his brain to that degree, that after his death there was nothing found in his skull but a little black lump, consisting of mere membranes.

Some people use the infusion of tobacco as an emetic; but it is a very dangerous and unjustifiable practice, and often produces violent vomitings, sickness and stupidity.

Bates and Fuller give some receipts, in which tobacco is an ingredient, with mighty encomiums in asthmatic cases. A strong decoction of tobacco, with proper carminatives and cathartics, given clyster-wise, sometimes proves of good effect in what is usually called the stone-cholic, and also in the iliac passion. A drop or two of the chemical oil of tobacco, being put on the tongue of a cat, produces violent convulsions, and death itself in the space of a minute; yet the same oil used in lint, and applied to the teeth, has been of service in the tooth-ach: though it must be to those that have been used to the taking of tobacco, otherwise great sickness, reachings, vomitings, &c. happen; and even in no case is the internal use of it warranted by ordinary practice.

A strong decoction of the stalks, with sharp-pointed dock and alum, is said to be of good service, used externally, in cutaneous distempers, especially the itch: some boil them for that purpose in urine. The same is said to be infallible in curing the mange in dogs.

Beat into a mash with vinegar, or brandy, it has been found serviceable for removing hard tumours of the hypochondria.

In the island of Ceylon, there are also two kinds of tobacco cultivated for profit. They call both kinds dunkol, which signifies a leaf, the use of which is to be smoked. The one sort they call hingele dunkol, or single dunkol; and the other dunkol kappada. The kappada tobacco is much stronger and more intoxicating than the other; but both kinds are the produce of the same plant, only the single tobacco has very little care taken of it, being, after the sowing, in a manner left to itself, while the other has great pains bestowed upon it during the whole time of its growth, and till it is fit for use, in the following manner: they clear a little piece of ground, in which they sow the seed of the tobacco, and against the time that the young plants have got three leaves a piece, they chuse out another piece of ground into which to transplant them: this they hedge round, and turn their horned cattle into it, that their dung may fall upon

on it and sufficiently enrich it. The ground is then dug with a sharp hoe, or spade, in the form of a pick-ax, and the dung, by this means, thoroughly worked into it. When the earth is thus prepared, they take up the young plants, and set them in this new ground, at about a foot square distant from one another.

The manner of giving more or less strength to this tobacco, is by suffering the plants to grow to a greater or less height before they top them, or cut off the stalk at the summit. The usual way is to cut off the top when the plant has fifteen leaves. If they intend the tobacco to be a little stronger, they do this when it has only thirteen; and, when they would have it strongest of all, they do it when there are only eleven or twelve leaves. On the contrary, when they would have a milder tobacco, they cut it not off till there be eighteen or twenty leaves, but, in this way of counting the leaves, they never reckon the three or four lowest, which do not grow so large and fine as the others. The cutting of the top prevents the juices of the plant from being wasted in flowers and seeds, which are of no value; and, in consequence of it, all being, after this time, employed to furnish the growth of the leaves, they grow four times as large and thick as they otherwise would do.

To prevent all unnecessary wasting of the sap, these plants are tended every day; and, as the young sprouts appear in the joining of the leaves and stalks, they are continually cut off: this is done once in three days, till the leaves have their full bigness, which is about that time when the flowers would have been ripe, had the plant been suffered to grow in its natural way: they are immediately to be gathered when they are full grown, otherwise they waste and decay. They cut down the whole plant, and bring them into their houses, laying them on a heap. When they have lain a little time together, they begin to sweat and grow hot: when they have been a little while fermenting, they turn them, bringing those which are in the middle to the surface, and placing those which were at the surface in the middle; by this means the whole quantity of leaves ferments equally. The longer they lie in this manner, the darker-coloured the tobacco becomes. When they have left it thus to sweat as long as they judge necessary, they hang every stalk separately on cords; and, when the whole is thoroughly dry, they carefully take off the leaves, and lay them by in bundles, till they have occasion for them. This is the manner of their preparing the kappada. The single tobacco is sown in the same manner with this; but it is never transplanted nor tended, it grows as it pleases, and, when the flowers are ripe, it is cut down, and laid carelessly in heaps, where some of it ferments too much, and some too little. This is much weaker therefore than the kappada; and, as both kinds are common in the place, the natives smook them either separately or together, mixed in different proportions, as they like. Some of the Ceyloneese chew this strong tobacco with their beetle, and some, who smoke it alone, use no pipe, but, taking a long leaf of it, they roll it up into a long form, and cover it with a leaf of the wattukan-tree; they then light one end of it, and smook by the other, till the whole is consumed. *Philos. Transf.* N^o. 278.

With regard to the manufacturing of tobacco after importation, it will be best understood from the following plates, and their description.

Plate CXXVIII.

Upper Compartment.

Is that part of a tobacco manufactory where the bundles of leaves are separated and distributed in the partitions F, F, G, G.

Fig. 1. A workman who cuts off from the mass of leaves contained in a hogthead all the parts that have been damaged by the sea, or other accidents. A, B, C, masses of leaves contained in separate hogheads.

Fig. 2. A workman who separates the bundles contained in the mass E, and distributes them in the partitions. F, D, is a wicker basket strengthened with ropes, and raised by the help of a pully, by which the picked leaves are hoisted up into a loft above this part of the

manufactory. H, H, H, H, rolls of tobacco placed above the partitions.

Middle Compartment; called the wetting house.

Fig. 1. A workman standing behind the table L, chusing from the bundles of leaves the longest and largest, as the most proper for covering the rolls of tobacco. These he sprinkles with water by means of a small besom; after which they are carried to the loft of the manufactory. C, a basket, in which the picked leaves are sprinkled. A, B, pails, in which the water is contained.

Fig. 2. A workman standing on a heap of leaves, sprinkling each layer with water, by means of a small besom composed of little twigs. F, G, are stone cisterns for holding water. D, a plank laid over the open part of the gutter or canal E, destined to carry off the superfluous water. The walls of this apartment are covered with thick boards, that the heaps of leaves may not touch them. It is also furnished with different tables, as M.

Lower Compartment.

Is a view of the same apartment or wetting-house; drawn on a larger scale. A, B, pails for holding the water. C, the basket into which the longest and largest leaves are picked. D, the plank that covers the open part of the gutter E. F, G, stone cisterns. H, K, besoms for sprinkling the layers of leaves, as they are laid in heaps.

Plate CXXIX.

Upper Compartment, called the stripping-house.

A, the aperture defended by rails, through which the leaves are drawn up in a basket, from the wetting-house, by means of the pully B, C.

Fig. 1, 2, 3, 4, 5. Benches, on which the boys sit; who are employed in separating or stripping the fine and tender parts of the leaves from the large fibres, or ribs; throwing the former into baskets placed before them; and the latter over the benches behind them.

Middle Compartment, called the spinning-house.

Fig. 1, 2, 3, 4, represents the manner of forming the tobacco into small ropes, or what is generally called pig-tail tobacco. These are made on a very high table divided by perpendicular boards into four equal compartments, before which the workmen or spinners stand. D, D (*fig. 2, and 3*) are the foot benches on which the workmen stand. *Fig. 1 and 4,* are empty compartments for two other spinners. One of these spinners (*fig. 2.*) takes in his hand a quantity of the leaves, proportioned to the size of the rope, and after rolling them a little on the table passes the end of the twisted rope to another spinner, supposed to be standing at the empty part (*fig. 1.*) who rolls it closer, and passes it to a boy supposed to be standing on the block *c* (*fig. 4.*). From this boy it passes to another standing on the block *c* (*fig. 3.*)

Fig. 5, 6, 7, 8, represent the manner in which the Dutch form these ropes, or pig-tail tobacco.

Fig. 5. a boy who turns the roller *f*.

Fig. 6. A spinner who unites the ropes, or threads spun by the other workman (*fig. 1, 2, 3, 4.*) and forms them into a new and larger rope.

Fig. 7. A boy who furnishes the threads to the spinner. *e*, is a dish containing a sponge filled with olive oil, which the spinner often rubs upon his hands, that the rope may pass with more facility between them and the table. Those who spin the first threads have also sponges filled with oil. *d*, a gudgeon of wood, over which the rope passes to the roller *f*, on which one end of its axis turns. *g*, a stancheon on which the other extremity of the axis turns. *b*, a basket containing the threads which the boy furnishes to the spinner.

Fig. 8. A spare table. *a*, the table. *a*, the gudgeon, on which one end of the roller's axis turns. *b*, the stancheon, on which the other extremity of the axis revolves.

Lower Compartment.

Fig. 9. Plan of the roller. It is of iron, and consists of a case or frame, of which the longer sides R S, T V, are perforated at G and F, with two round holes, for receiving the pivots of the arbor A, on which it revolves. The longer sides are connected together by means

means of the traverse piece S V, and the parts R D, T D, which join at the socket D, through the aperture of which the thread passes. The extremities of the arbor A, are terminated by two circles N O, P Q, the elevation of which is seen in the profil (fig. 10.) and fixed on their inner side by two iron plates. In the middle of the traverse piece S V, is fixed a large iron pin H, which forms the pivot of the arbor. At the extremity of that pivot is a screw, which receives the aperture K, of the winch K L. The handle L, is moveable at the pivot which connects it to the winch. The pivot H, revolves on the gudgeon on the top of the stancheon g, and the socket D, is that fixed on the table at d (fig. 5.)

Fig. 10. Is a profil of the roller. Q, the elevation of one of the circles fixed to the extremity of the arbor. A, a denticulated wheel fixed on the square extremity of the pivot G (fig. 9.). B, a catch, which is continually pushed against the teeth of the denticulated wheel, by means of the spring C. M, a pin with an eye, which by means of a screw fastens the end of the catch B, to the side of the frame, and which is taken out when the arbor is charged with a sufficient quantity of the spun rope.

Plate CXXX.

Upper Compartment, called the rolling-house.

Fig. 1. A workman, who unwinds the rope from the roller f, moving on the two gudgeons d, e, and passes it to the roller.

Fig. 2. The roller. This workman has before him an instrument (represented at large, fig. 6. in the lower compartment) called a matrix, furnished with two pins of wood, round which he winds the rope (as represented at fig. 5. in the lower compartment). After taking three turns about the pins he fastens them together, as represented in the figure, and takes coil from the matrix. This coil forms the center and mould of the roll. Having thus formed the mould, he coils or rolls the rope round it in the manner represented in fig. 2. where a is the rope coming from the roller, b the roll, c a wooden mallet with which he often strikes the rope, in order to make it lie close in the roll.

Fig. 3. is another table for the same purpose.

Fig. 4. is a perspective view of the press for pressing the rolls. It is composed of two thick planks of elm. The upper is pierced with two holes, through which the wooden screws A C, B D, pass. The under plank is also pierced, but the holes are female screws. On the under plank the rolls of tobacco, as D, E, F, are placed and pressed, by turning the screws, with the lever G.

Middle Compartment, called the cutting-house.

Fig. 1. The cutter standing at a table, and having before him a roll of tobacco, a d, mounted on a machine represented in the lower compartment of the plate. And taking the end of the rope in his hand, he applies it to the matrix or measure lying before him, and with a knife cuts it into lengths, and lays them together as at e. In this manner he continues his work till the whole roll is cut into proper lengths. b, c, is an upright piece, pierced with a long mortise thro' which the extremity of the arm a b, which carries the superior pivot, passes, and is fixed at a height proportioned to that of the roll. f, a support for the candle, g, a basket, in which the lengths are carried to be deposited, according to their lengths and qualities, in proper cases.

Fig. 2. represents the cases, in which the above lengths are deposited.

Lower Compartment.

Fig. 3. The cutting table, in another point of view, drawn on a larger scale. A B C D, the machine on which the roll is mounted. D C, its foot. B C, its vertical post, pierced with a long mortise. The sides of this post are also pierced with several round holes, for receiving an iron pin, which fixes the arm at any determined height. A B, the arm whose tenon passes thro' the above mortise. A, the superior pivot, which enters the center of the roll. F, a round copper plate, which is fixed upon the foot of the machine by four wooden screws. The pivot turns in the center of that plate. The upper part of the pivot is square, and received in a hole G, of which the plan is represented at H. E, the board on which the cutter cuts his lengths.

Fig. 4. The cutting knife.

Fig. 5. The matrix charged with a skain.

Fig. 6. The matrix separately.

Fig. 7. The mallet used by the workman, who forms the rolls.

Fig. 8. The matrix with which the cutter measures his lengths. r s, a view of the upper side of the matrix. t u, a view of the lower side.

Fig. 9. A single length of the rope, equal to the length of the matrix.

TOD of Wool, a quantity containing twenty-eight pounds, or two stone.

TOES, called by anatomists *digiti pedis*, are the extreme divisions of the feet, answering to the fingers of the hands.

The bones of the toes of both feet are twenty-six in number, sometimes twenty-eight; being much slenderer, except that of the great toe, than those of the fingers: they have also a much less free motion than those of the fingers: the great toe has only two bones, and the rest three; except the little toe in very old people, in whom the two extreme phalanges of the little toe grow together, so as to form only one bone; whence we find, in this case, fewer bones in each foot than thirteen.

Adhesions of the TOES.—It is a frequent thing to meet with new born infants with their fingers or toes cohering or grown together, either by a strict adhesion of flesh, or else by some loose productions of the skin, as in the feet of ducks and geese; and a disorder of the same kind is also sometimes found in adults, from accidents; as when the fingers and toes have been neglected, after an excoriation of them by burns or wounds. In both these cases the surgeon's assistance is necessary, partly to remove the deformity, and partly to restore the proper use of the fingers.

These adhesions, according to the nature of the disorder, are to be separated two ways, either by cutting out the intermediate skin with a pair of scissars, or else barely by dividing them from each other with the same instruments. When this is done, to prevent their cohesions again, each finger must be invested separately with a spiral bandage about an inch broad, dipped in lime-water and spirit of wine.

Sometimes the fingers, instead of adhering to each other, grow to the palm of the hand, from wounds or burns, so that they cannot be by any means extended, or drawn back to open the hand. The method of relieving this disorder is first very carefully to separate the fingers from their adhesions to the palm, without injuring their tendons; then dress them with a vulnerary balsam, and scraped lint, and extend them on a ferula or thick pasteboard; and let them remain in this extended posture, separately to be dressed till they are perfectly healed; but at every dressing they must be gently moved, to prevent a rigidity or stiffness of the joints. *Heister's Surgery.*

TOGA, in Roman antiquity, a wide woollen gown or mantle; which seems to have been of a semi-circular form, without sleeves; differing both in richness and largeness, according to the circumstances of the wearer, and used only upon occasion of appearing in public.

Every body knows that the toga was the distinguishing mark of a Roman: hence, the *jus togæ*, or privilege of the toga, was the same with the privilege of a Roman citizen; that is, the right of wearing a Roman habit, and of taking, as they explain it, fire and water through the Roman empire.

TOILS, snares or nets used by hunters for catching wild beasts, as deer, &c.

TOILET, a fine cloth of linen, silk, or tapestry, spread over the table in a bed-chamber or dressing room, to undress and dress upon.

TOISE, a French measure containing six of their feet, or a fathom.

TOISON D'OR, a term, in heraldry, for a golden fleece, which is sometimes borne in a coat of arms.

TOLERATION, in matters of religion, is either civil or ecclesiastical. Civil toleration, is an impunity and safety granted by the state to every sect that does not maintain doctrines inconsistent with the public peace: and ecclesiastical toleration, is the allowance which the church

church grants to its members to differ in certain opinions not required fundamentals.

The term toleration has made a great figure in the disputes among protestants who have been exceedingly divided about the measures of toleration, or the degrees to which heretics and schismatics are, or are not to be suffered.

TOLL, in law, denotes a tax or custom paid for passage, or for the liberty of selling goods in a market or fair. Hence, toll booth is a place in a town, where goods are weighed, in order to ascertain the duties thereon.

TOLLEON, among the Romans, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another, more than twice as long, and moveable upon a center; on one end of this cross-beam were placed a covering of hurdles or planks, within which a few soldiers were put, and by pulling down the other end with ropes, these were raised above the walls of a besieged town.

TOLUERA, in botany, a genus of plants, the flower of which is composed of five petals, which are inserted into the cup; four of these are straight and equal in size, and are a little longer than the cup; but the fifth is twice as large as these, and is cordated at the end, and has an unguis of the length of the cup. The fruit and seeds are yet unknown. It is so called, from its producing the balsam of Peru. See the article **BALSAM**.

TOMAN, or **TOUMAN**, a kind of imaginary money used among the Persians in the keeping of their books, and to facilitate the reduction of money in the payment of considerable sums. See the article **MONEY**.

TOMB includes both the grave or sepulchre where in a deceased is interred, and the monument erected to preserve his memory.

TOME, in matters of literature, denotes a bound book, or writing that just makes a volume.

TOMENTUM properly signifies flocks or locks of wool; but by botanists is used for that soft downy matter which grows on the leaves of some plants.

TOPE, or **TUNE**, in music, a property of sound, whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of tones.

Tone is more particularly used for a certain degree or interval of tune, whereby a sound may be either raised or lowered from one extreme of a concord to the other, so as still to produce true melody.

TONGUE, *lingua*, in anatomy, the primary organ of taste and speech; the figure of which approaches in some degree to pyramidal; its anterior part being called apex, and its posterior part the base or root. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow deffelled line called *lingua lingua mediana*. The edges are thinner than the other parts, and a little rounded as well as the point. The lower side reaches only from the middle of the length of the tongue to the point.

The tongue is principally composed of very soft fleshy fibres, intermixed with a peculiar medullary substance, and disposed in various manners. Many of these fibres are confined to the tongue without going any farther; the rest form separate muscles, which go out from it in different ways, and are inserted in other parts: all the upper side of the tongue is covered by a thick membrane of a papillary texture, upon which lies another very fine membrane like a kind of epidermis, which is likewise continued over the lower side, but without papillae.

Three sets of papillae may be distinguished in the upper side of the tongue, capitate, semi-lenticular, and villiform. Those of the first kind are the largest, resembling little mushrooms with short stems or buttons with-out a neck: they lie on the base of the tongue, in small superficial follicles. They resemble small conglomerate glands, seated on a very narrow base, and each of them has sometimes a small depression in the middle of their upper convex side: they occupy the whole surface of the base of the tongue, and are situated near each other, in such a manner, as that the most anterior form an angle; they are glandular papillae, or small salivary or mucilag-

nous glands, of the same kind with those that are to be described hereafter.

We often observe, about the middle of this part of the tongue, a particular hole of different depths; the inner surface of which is entirely glandular, and filled with small papillae like those of the first kind. It is called *foramen caecum Morgagnii*, as being first discovered by that author; since that time Vaters has discovered a kind of similar ducts belonging to it; and Heister found two of these ducts very distinctly, the orifices of which were in the bottom of the *foramen caecum* near each other. He observed the ducts to run backward, dividing a little from each other; and that one of them terminated in a small oblong vesicle, situated on the side of the small con-duit of the *foramen*.

The papillae of the second kind, or semi-lenticular, are small orbicular eminences, only a little convex, their circular edge not being separate from the surface of the tongue. When we examine them in a good tongue with a good microscope, we find their convex sides full of small holes or pores, like the end of a thumb.

They lie chiefly in the middle and anterior portions of the tongue, and are sometimes most visible on the edges, where they appear to be very smooth and polished even to the naked eye, and sometimes in living subjects. They soon lose their consistence after death, so that by rubbing them several times, they may be drawn out in form of small soft pyramids, inclined to one side. The papillae of the third kind, or villiform, are the smallest and most numerous. They fill the whole surface of the upper side of the tongue, and even the interstices between the other papillae. They would be more properly named papillae conicæ, than villiform, from the figure which they appear to have, when examined through a microscope in clear water. They are naturally soft, but become extremely rigid after death; so that by spreading them they may be made short and thick, whereas they are naturally long and small.

The fleshy fibres of which the tongue is composed, and which go no farther than the tongue, may be termed *musculi linguae interni*, or the intrinsic muscles; and they are the same with what physicians named *musculi linguae interni*. The fibres which consist of are of three general kinds, longitudinal, transverse, and vertical; and each of these formaments admits of different degrees of obliquity.

The longitudinal fibres point to the base and apex of the tongue, and seem partly to be expansions of the *musculus stylo-glossus*, *hyo-glossus*, and *genu-glossus*. The vertical fibres seem likewise to be in part produced by the same *genu-glossus*, and the transverse by the *stylo-glossus*.

Besides these mixed productions, there is a distinct plane of longitudinal fibres, which run near the surface of the upper side of the tongue, and a distinct transverse plane under them. All these fibres are partly interwoven, one portion of them terminating at the two edges of the tongue, and the other at the base and point, without going to any other part; and they lie immediately above those which belong to the *genu-glossus*. To discover all these different fibres, and their different degrees of direction, we need only cut the tongue longitudinally, after it has been boiled, or long macerated in strong vinegar. The extrinsic muscles or muscular extensions, are those which by one extremity make a part of the body of the tongue, and are fixed by the other in some part without the tongue. Of these we reckon four pairs, *stylo-glossus*, *hyo-glossus*, and *genu-glossus*. In plate CXXXI. is represented the human tongue, with its three integuments, which anatomists in general have omitted to remark. Bourdon, indeed, has figured them, but thicker than the life. A A A is the upper superficies of the tongue, on which are visible a multitude of papillary and pyramidal eminences. B is a piece of the exterior tunic, or coat of the tongue; in which are discernible a vast number of nervous papillae, adhering to its interior surface. C C is the second tunic, called the *corpus reticulatum* of Malpighi. D is the corpus reticulatum of other writers. E is the membrane, or corpus papillare nervosum. F F the glands of the tongue; and G the tonsils usually found in the hinder part of the tongue.

church grants to its members to differ in certain opinions, not reputed fundamentals.

The term toleration has made a great figure in the disputes among protestants, who have been exceedingly divided about the measures of toleration, or the degrees to which heretics and schismatics are, or are not to be suffered.

TOLL, in law, denotes a tax or custom paid for passage, or for the liberty of selling goods in a market or fair. Hence, toll booth is a place in a town, where goods are weighed, in order to ascertain the duties thereon.

TOLLENON, among the Romans, a warlike machine, formed in this manner: one beam was fixed very deep in the earth, and on the top of it another, more than twice as long, and moveable upon a center; on one end of this cross-beam were placed a covering of hurdles or planks, within which a few soldiers were put, and by pulling down the other end with ropes, these were raised above the walls of a besieged town.

TOLUIFERA, in botany, a genus of plants, the flower of which is composed of five petals, which are inserted into the cup; four of these are straight and equal in size, and are a little longer than the cup; but the fifth is twice as large as these, and is cordated at the end, and has an unguis of the length of the cup. The fruit and seeds are yet unknown. It is so called, from its producing the balsam of Peru. See the article **BALSAM**.

TOMAN, or **TOUMAN**, a kind of imaginary money used among the Persians in the keeping of their books, and to facilitate the reduction of money in the payment of considerable sums. See the article **MONEY**.

TOMB includes both the grave or sepulchre wherein a defunct is interred, and the monument erected to preserve his memory.

TOME, in matters of literature, denotes a bound book, or writing that just makes a volume.

TOMENTUM properly signifies flocks or locks of wool; but by botanists is used for that soft downy matter which grows on the leaves of some plants.

TONE, or **TUNE**, in music, a property of sound, whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of sonorous bodies.

Tone is more particularly used for a certain degree or interval of tune, whereby a sound may be either raised or lowered from one extreme of a concord to the other, so as still to produce true melody.

TONGUE, *lingua*, in anatomy, the primary organ of taste and speech; the figure of which approaches in some degree to pyramidal; its anterior part being called apex, and its posterior part the base or root. The upper side is not quite flat, but a little convex, and divided into two lateral halves, by a shallow depressed line called *linea linguæ mediana*. The edges are thinner than the other parts, and a little rounded as well as the point. The lower side reaches only from the middle of the length of the tongue to the point.

The tongue is principally composed of very soft fleshy fibres, intermixed with a peculiar medullary substance, and disposed in various manners. Many of these fibres are confined to the tongue without going any farther; the rest form separate muscles, which go out from it in different ways, and are inserted in other parts: all the upper side of the tongue is covered by a thick membrane of a papillary texture, upon which lies another very fine membrane like a kind of epidermis, which is likewise continued over the lowest side, but without papillæ.

Three sorts of papillæ may be distinguished in the upper side of the tongue, *capitata*, *semi-lenticularis*, and *villosa*. Those of the first kind are the largest, resembling little mushrooms with short stems, or buttons without a neck: they lie on the basis of the tongue, in small superficial fossulæ. They resemble small conglomerate glands, seated on a very narrow basis, and each of them has sometimes a small depression in the middle of their upper convex side: they occupy the whole surface of the basis of the tongue, and are situated near each other, in such a manner, as that the most anterior form an angle; they are glandular papillæ, or small salival or mucilagi-

nous glands, of the same kind with those that are to be described hereafter.

We often observe, about the middle of this part of the tongue, a particular hole of different depths; the inner surface of which is entirely glandular, and filled with small papillæ like those of the first kind. It is called *foramen cœcum Morgagnii*, as being first described by that author; since that time Vaterus has discovered a kind of salival ducts belonging to it; and Heister found two of these ducts very distinctly, the orifices of which were in the bottom of the *foramen cœcum* near each other. He observed the ducts to run backward, divaricating a little from each other; and that one of them terminated in a small oblong vesicle, situated on the side of the small cornu of the *os hyoides*.

The papillæ of the second kind, or *semi-lenticulares*, are small orbicular eminences, only a little convex, their circular edge not being separate from the surface of the tongue. When we examine them in a sound tongue with a good microscope, we find their convex sides full of small holes or pores, like the end of a thimble.

They lie chiefly in the middle and anterior portions of the tongue, and are sometimes most visible on the edges, where they appear to be very smooth and polished even to the naked eye, and sometimes in living subjects. They soon lose their consistence after death, so that by rubbing them several times, they may be drawn out in form of small soft pyramids inclined to one side. The papillæ of the third kind, or *villosæ*, are the smallest and most numerous. They fill the whole surface of the upper side of the tongue, and even the interstices between the other papillæ. They would be more properly named *papillæ conicæ*, than *villosæ*, from the figure which they appear to have, when examined through a microscope in clear water. They are naturally softish, but become extremely flaccid after death; so that by handling them they may be made short and thick, whereas they are naturally long and small.

The fleshy fibres of which the tongue is composed, and which go no further than the tongue, may be termed *musculi linguæ interiores*, or the intrinsic muscles; and they are the same with what Spigelius named *musculi linguales*. The fibres these muscles consist of are of three general kinds, longitudinal, transverse, and vertical; and each of these situations admits of different degrees of obliquity.

The longitudinal fibres point to the basis and apex of the tongue, and seem partly to be expansions of the *musculi stylo-glossi*, *hyo-glossi*, and *genio-glossi*. The vertical fibres seem likewise to be in part produced by the same *genio-glossi*, and the transverse by the *mylo-glossi*.

Besides these mixed productions, there is a distinct plane of longitudinal fibres, which run near the surface of the upper side of the tongue, and a distinct transverse plane under them. All these fibres are partly interwoven, one portion of them terminating at the two edges of the tongue, and the other at the basis and point, without going to any other part; and they lie immediately above those which belong to the *genio-glossi*. To discover all these different fibres, and their different degrees of direction, we need only cut the tongue longitudinally, after it has been boiled, or long macerated in strong vinegar. The extrinsic muscles or *musculi exteriores*, are those which by one extremity make a part of the body of the tongue, and are fixed by the other in some part without the tongue. Of these we reckon four pair, *mylo-glossi*, *stylo-glossi*, *hyo-glossi*, and *genio-glossi*. In plate CXXXI. *fig. 1.* is represented the human tongue, with its three integuments, which anatomists in general have omitted to remark. Bourdon, indeed, has figured them, but thicker than the life. AAA is the upper superficies of the tongue, on which are visible a multitude of papillary and pyramidal eminences. B is a piece of the exterior tunic, or coat of the tongue; in which are discernible a vast number of nervous papillæ, adhering to its interior surface. CC is the second tunic, called the *corpus reticulare of Malpighi*. D is the *corpus reticulare* of other writers. E is the membrane, or *corpus papillare nervosum*. FF the glands of the tongue; and G the *foramen* usually found in the hinder part of the tongue.

4 L

Fig.

Fig. 2 exhibits a human tongue, in which Heister discovered two remarkable salival ducts, *b* and *d*, in the foramen cecum *A*; *c* is a vesicle at the extremity of the duct *d*, distended with saliva: and *e* is the place where this duct disappeared; *f* shew the course and situation of these ducts. The fabric and structure of the oscula, expressed at *b* and *d*, was singular, having the appearance of valves or caruncles, that had collapsed, so that they did not appear as represented in the figure, unless forced open by inflation: *h* is the epiglottis: *i* its anterior ligament: *k* muscular fibres arising from the substance of the tongue: *l* two little ossicles of the os hyoides: *m* glands and papillæ of various sizes, about the middle of the tongue: and *o* the apex of the tongue bent downwards.

TONGUE-tied, the popular name for a distemper of the tongue in children, when it is tied down too close to the bottom of the mouth, by a ligament connected all along its middle, and called its frænulum, which requires to be divided, to give the tongue its proper motion.

This is sometimes the case in adults, but more frequent in children, who cannot then exert their tongue to suck. This is, however, by no means so common as the women usually imagine; not so much as one child in a thousand being afflicted with it; nor is the operation in cutting it of little consequence, since often bad accidents follow it, and sometimes the loss of the child's life. When the infant can put its tongue out of its mouth, the frænulum wants no incision; but when the tongue cannot be extended beyond the teeth, the operation is necessary. To perform this, the end of the tongue should be covered with a linen rag, and held with the fingers to prevent its slipping, and the ligament of the tongue running between the ranular veins and internal salival ducts, is to be divided by a pair of obtuse-pointed scissors, till it give room enough for sucking or speaking: but in doing this great care must be taken not to wound the salival ducts, or the proper veins and arteries of the tongue; for children have been known to perish upon the spot, from the cutting the ranular veins in this operation. Midwives often tear this ligament with their fingers as soon as the child is born, but this is a dangerous and bad practice.

TONIC, *τονικόν*, in medicine, is applied to a certain motion of the muscles, wherein the fibres, being extended, continue their extensions in such a manner, as that the part seems immovable, though in reality it be in motion.

TONSILS, *tonsillæ*, in anatomy, two remarkable glands situated one on each side of the mouth, near the uvula, and commonly called almonds of the ears, from their resembling almonds in figure.

Their use is to secrete a mucous humour for lubricating the passages: this they discharge by several irregular but conspicuous foramina into the mouth.

The tonsils are apt to be inflamed from taking cold, for which Heister first advises a gentle purge of tamarinds, sena, and cream of tartar; and this is to be repeated to the third or fourth dose, if there be occasion: in the intermediate times, the diaphoretic, attemperating, and nitrous medicines are to be given in powders, and a large quantity of diluting liquors allowed, which should be gently acidulated, and have a small quantity of nitre dissolved in them: gargarisms made of decoctions of bistort-root, red-roses, and other gentle astringents, are also to be frequently used; and the frequent washing the feet in warm water, often has a very remarkable good effect.

If after four or five days the distemper is found not to give way to these means, but the tumour still remains, there is then but little hopes to be had of its resolution, and a very different end is to be attempted: emollient gargarisms are now to be used, and maturing plaisters externally applied, such as diachylon with the gums, and the like; and suppurating cataplasms are to be applied to the whole neck and throat: these methods are to be continued till the tumour either bursts of itself, or is so ripe as to be fit for opening by the hand of the surgeon. After this has been done, and the matter is discharged, gargarisms must be used of decoctions of some vulnerary herb; or common green tea, sweetened with honey of roses, may be used to serve the purpose. The mouth and throat are to be frequently washed with this till the part is healed. It is to be observed, however, that the resolution of these tumours is never to be despaired of, not even

during the use of the suppurating medicines, for it is often seen that the tumour has been wholly dissolved even during the use of these means, the resolution often being extremely slow.

This is a very troublesome complaint, and with some persons is apt to return very frequently; the best preservative against it is a moderate diet and bleeding, about the time of the equinoxes, either in the arm or foot. Some have found it necessary to open an issue in the arm, in this case, and have been by this means perfectly cured; but on its drying up have always found the disease return.

TONSURE, in ecclesiastical history, a particular manner of shaving or clipping the hair of ecclesiastics or monks.

The antient tonsure of the clergy was nothing more than polling the head, and cutting the hair to a moderate degree, for the sake of decency and gravity; and the same observation is true with respect to the tonsure of the antient monks. But the Romanists have carried the affair of tonsure much farther; the candidate for it kneeling before the bishop, who cuts his hair in five different parts of the head, viz. before, behind, on each side, and on the crown.

TOOL, among mechanics, denotes in general any small instrument, used as well for making other more complex instruments and machines, as in most operations in the mechanic arts.

TOOTH, *dens*, in anatomy, a little, hard, smooth bone set in the gums, and serving to masticate or chew the food, &c.

As every part of the human body loudly proclaims the ineffable wisdom and diffusive goodness of its glorious architect and contriver; so also the teeth, their exquisite order, and curious structure, are so many proofs richly pregnant with irrefragable arguments for the stupendous and amazing power of the venerable Being who formed them. The first memorable circumstance which occurs with respect to the nature of these substances is, that in hardness and durable texture they far surpass all other parts of the body. Hence, according to Tertullian, in his treatise *De Resurrectione*, the mistaken piety of the ancients induced them to bury the teeth in the earth, since they remained sound for several hundreds or thousands of years; and their design in this practice was to render the body entire at the resurrection. When we reflect upon the beautiful order and disposition with which they are ranged in the extremities of both maxillæ, or jaw-bones, we cannot fail to be struck with awful impressions of the exquisite skill and curious contrivance with which they are formed; for they are so situated, that the superior and inferior rows are indeed capable of being joined, though not all at one and the same time, that by this means the actions of incision and mastication may be varied at pleasure; for when the dentes molares are joined, the anterior teeth of the superior row project beyond, and partly cover their corresponding teeth of the inferior row. But when the extremities or points of the anterior teeth are joined, the dentes molares remain at a distance from each other, by which means they enjoy rest, and are subjected to action reciprocally, and by turns. This surprising instance of art and design long ago appeared to Galen, as we learn from his treatise *De Ossibus*, abundantly sufficient to refute those ludicrous calumniators of Nature, who ascribe the most curious of her productions to a casual and fortuitous concurrence of atoms. Without this mill, as it may be called, of the microcosm, a due mastication, which as Helmont excellently observes, in his treatise *de Victus Ratione*, greatly contributes to the preservation of life, cannot be performed.

We shall therefore at present consider their nature and structure, their connection and use, the several causes by which they are injured, and the various medicines accommodated to remove the misfortunes and indispositions to which they are subject. Omitting therefore too minute and prolix disquisitions with respect to the name, we shall only observe, that in former ages they were called *dentes*, as it were from *edentes*. The teeth then are bony parts of the body, consisting of two substances, the one intensely hard, and as it were of a strong texture, and the other softer, but also of a bony nature. Internally they

they are furnished with a certain cavity; they are fixed in the sockets of the maxillæ, by that particular species of articulation called gomphosis; and are destined for the purposes of mastication, articulation of the voice, and ornament. First, then, we are to observe, that the teeth consist of two substances, the exterior of which is highly hard like a stone, though it does not partake of a stony nature; as is obvious from putting an entire human tooth into a sufficient quantity of aqua fortis for some hours, by which it is entirely dissolved, whilst there remains a very small quantity of a glutinous substance, which seems to be a sulphureous and somewhat pinguious portion of the teeth. If to the solution, when sufficiently saturated, we add oil of tartar per deliquium, there is produced a highly white magistery, in medicinal virtues agreeing with that prepared from the boar's teeth, or the elk's hoof. But such a chemical solution cannot be produced with respect to flints and genuine stones. The exterior substance, however, of the teeth is so hard and solid, that by a violent attrition or concussion with iron, it emits large quantities of sparks. But this only holds true with respect to the dentes molares of the larger animals, which are capable of making a considerable resistance. This hard and stony part of the teeth is only observed in those portions of them which lie without the sockets of the gums, and like a bark or covering surround the bony part of the teeth; for the roots of the teeth, which are concealed in the sockets and gums, are only of a bony nature, and consequently of a colour not so white and splendid as the external part which is uncovered. But the external part is the hardest, not only that it may be proof against wounds and injuries, but also, that it may be the better qualified for incising and breaking the aliments. The interior bony matter, on account of the greater laxity of its pores, is more easily dissolved and consumed: Hence it is covered with an external harder bark, lest, perhaps, some of the more acrid and corrosive parts of the aliments should injure or destroy it. This internal substance of the teeth is that part principally affected in a caries; for the external covering is rarely seen totally, but only partially consumed: besides, the structure of the external stony covering of the teeth differs from that of the internal part; for in the former, the striæ, or furrows, terminate obliquely in small circles; but the interior softer part of the teeth consists of several layers of fibres, longitudinally laid over each other. When a resolution is made by a long maceration of the bones, these layers become sufficiently conspicuous; for the bony reticular plates may by this means be separated entire.

Anatomists have observed, that a certain cavity is formed in the teeth, which is sufficiently conspicuous when a tooth is cut longitudinally in the middle; on which occasion we observe, that all the roots of the teeth are furnished with that peculiar cavity, which is very considerable in the base of the tooth itself, or that part of it which appears without the gums; for in the cavities of the teeth of every animal, there is always found a mucous, membranaceous substance, or a certain small mucous end, in the form of an oblong bladder, composed of highly slender blood-vessels, nervous membranes, and a certain glutinous substance. This also reaches to the very extremities of the teeth, where its membranes being more contracted, it appears somewhat harder and redder. In foetuses and children this cavity is sufficiently large, and according to Eustachius, in his treatise de Dentibus, divided till the seventh year of their age like honeycombs; but it is smaller in adults. In children this cavity is filled with a mucous matter, surrounded with a membrane whose external surface is reddish, but internally it appears more white; and the mucus itself, being the general nourishment of the teeth, is at last converted into their substance; for we observe, the more solid and firm the substance of the teeth becomes, as in adults, the smaller quantity of this mucus is found; whereas, in infants whose teeth consist of small and tender laminae, a large quantity of it is observable. In the teeth of calves, especially what is called the sweet-tooth, this matter may be commodiously seen with the naked eye: in its surface some traces of blood discover themselves by a reddish colour; and, when the mucous matter is compressed, it actually discharges blood.

All the teeth without exception, are so firmly fixed in their sockets, like so many wedges, by that species of articulation called gomphosis, that in mastication they remain steady and immovable. Besides, the teeth are not all fixed in their sockets by an equal number of roots, for the incisores are only secured by one: the canini have also but one, which, however, is deeper than those of the incisores, and larger in proportion to the strength of the canini. And among the incisores, the two in the middle are secured by deeper roots than the two lateral ones contiguous to the canini, because they are broader and larger. The dentes molares differ from each other with respect to their roots: the superior, and especially the two posterior, are sometimes fixed with three roots, but the inferior have only two, partly because the substance of the superior jaw is softer and less compact than that of the inferior, for which reason they could not be so securely fixed by two as by three roots; and partly because the inferior press upon their roots by their own weight, whereas the superior are pendulous, and consequently require more roots to secure them.

The other dentes molares, succeeding the dens caninus in the upper jaw, have two roots, and those in the inferior only one. Besides, it is to be observed, that the teeth of children are only furnished with imperfect, soft, and as it were medullary roots: hence they are generally loose, especially the incisores, which may be pulled out with one's nails, or by a piece of thread twisted about them. It is also to be observed, that the roots of the teeth are internally surrounded with membranous and nervous ligaments, by which the teeth are firmly secured in their sockets; and externally the teeth are encompassed by the substance of the gums, which are a kind of hard flesh, consisting of small fibrous laminae placed close to each other, and intermixed with a large number of blood-vessels, for which reason they are intensely red. They are besides liberally furnished with slender membranes, glands, and ramifications of nerves; hence they derive their power of sensation, and are observed to be moistened with a due humidity. This flesh surrounds the teeth like a rampart, and fortifies them as muscles do: hence, when it is either eat away, or become preternaturally flaccid, the teeth generally become loose, or drop out; but the membrane which surrounds the roots of the teeth, and that part of them which is covered, as Clopton Havers in his Osteology justly observes, is not a continuation of the maxillary periosteum, but rather a propagation of that membrane which is contiguous to the gums, and is common to the whole mouth, which is really glandular, and which does not terminate with the gums, but as soon as it arrives at their margins, is intorted and reflected betwixt the inside of the gum and the tooth; but it descends into the sockets, and adheres immediately to those parts of the teeth which are lodged in them. From the root of some teeth, especially those of the upper jaw, together with this membrane, there is something of a hard and fleshy nature communicated to the substance of the gums, by which the teeth are more securely fixed in their sockets. And though the teeth themselves do not partake of the common periosteum, yet their sockets are furnished with it, and it so coalesces and unites with the membrane which covers the teeth, that they seem to form but one and the same body.

From a peccant nourishment proceed these concretions about the teeth and gums, which are commonly called the tartar of the teeth. Helmont is of opinion, that the gums supply the teeth with nourishment; and when this nutritive juice is excrementitious, and discharged from the injured gums, it indurates about the teeth, and assumes a degree of hardness almost equal to their own. However, it is probable that the tartareous matter adhering to the teeth is produced partly from the saliva, impregnated with the terrestrial tartareous lymph of the gums, which by continually moistening the teeth, gradually adds viscid and tartareous particles to them.

This tartar, in consequence of its acrimony, gradually consumes the substance of the teeth, induces a blackness, and sometimes a caries. This tartareous substance is instantaneously resolved by being rubbed with spirit of salt, which is a proof that it consists of an alkaline earth. This disorder is generally most incident to infants, and children

dren who feed upon viscid preparations of milk and sweetmeats, as also to scorbutic, arthritic, nephritic, and hypochondriac patients; because their serum abounds with impure, terrestrial, and tartareous parts. For this reason physicians ought carefully to inspect the teeth, because by their state that of the serum and lymph are most satisfactorily discovered.

TOOTH-ACH.—The tooth-ach seems to be a particular species of rheumatism; for, in practice, we often observe pains of the joints, scapulæ, and shoulders, translated to one side of the head, the teeth of which they attack in a most violent manner. On the contrary, pains of the head and teeth are observed frequently to change their seat and fall down upon the shoulders, arms, and the scapulæ. As a rheumatism is produced by an intemperance or sudden change of air, so also a tooth-ach is generally excited in such as are previously disposed to it, especially if they happen to be of a cacochymic habit, by their suddenly removing from a warm to a cold air; or by the sudden vicissitudes of heat and cold in the spring and autumn. As rheumatisms are more incident to women than men, so also are tooth-achs, and that for the same reasons: besides, though these two disorders are less frequently incident to men than women, yet they generally prove far more severe in the former than in the latter. There is a certain analogy not only between a rheumatism and a tooth-ach, but also between a tooth-ach and a gout; for as arthritic disorders are accompanied with pain, redness, swelling, and a slight fever, so the same symptoms are observed to attend a tooth-ach. Besides, it is confirmed by experience, that such as are subject to rheumatic or arthritic disorders are rarely afflicted with tooth-achs, but for the most part have their teeth sound and entire: whereas those that are free from those disorders of the muscles and joints, are generally for that reason more subject to tooth-achs. As in rheumatisms and gout, so in tooth-achs, those who have been once afflicted are easily, and by every slight cause, subjected to fresh attacks of the disorder, on account of the weakness which these disorders generally leave in the parts; so that a gout, rheumatism, and a tooth-ach seem to be but one and the same disease appearing with different degrees of strength, attacking different parts, and therefore accompanied with symptoms seemingly different, though produced by one common cause. Hence it follows, that the regimen and method of living proper in one of these disorders, must of course be in the other also: but these things are so obvious to every person who will only allow himself to think, that there is no necessity for a longer or more explicit illustration of them. When tooth-achs are so intensely violent, as to resist the force and elude the efficacy of all other medicines, Hoffman tells us that he has observed a very singular and unexpected relief afforded by the following pills invented by himself.

Take of the pilulæ aloephanganæ one dram, of the pilulæ de styrace half a dram, and of the extract of saffron six grains; mixt up into a mass, of which form sixty pills; six or eight of which are to be exhibited for a dose.

Sometimes tooth-achs are so violent and intolerable, that they obstinately resist the best chosen and most efficacious medicines, in which case the means of relief are only to be obtained from manual operation: for, first, the pains are either to be alleviated by scarifying the gums, as Pliny, in the seventh chapter of his thirty-second book, has long ago observed; and this method is frequently practised; or secondly, an actual cautery, adapted to this end, is to be plunged into the cavities of the carious teeth: or thirdly, the part behind the ear, by anatomists called antitragus, is to be cauterized, or have an incision made in it; or, according to Schelhammer, it is to be strongly compressed with the fingers: or, in the fourth and last place, the corrupted and carious tooth is to be extracted.

As to the cleansing of foul teeth, see the article **DENTIFRICE**.

TOOTH-DRAWING, the operation of pulling out a carious, or otherwise injured tooth.

This art, according to Cicero, was invented by Æsculapius, in whose temple the ancients hung up a pair of leaden pullicans, very properly signifying that no teeth

were fit to be pulled out, but such as might be removed with a leaden forceps; that is, such as were loose and ready to fall out of themselves; for they very little consult their own welfare, who pull out their teeth while firm and sound: for drawing the teeth is not only a painful operation, but often brings on bad accidents, and sometimes even hazards the patient's life.

Tooth-drawing, however wrong in many cases, yet is certainly right and necessary in others. 1. In children, for the removing their lacteal, or deciduous teeth; for when these are left too long in their sockets, they displace the new ones, and turn them awry. 2. In infants it is also necessary to draw such teeth as grow out of the palate, or out of improper parts of the mouth, and are placed so as to impede their speaking or sucking. 3. In the tooth-ach proceeding from a tooth's being carious, and giving way to no medicines, drawing is the last resort, and is absolutely necessary. 4. Those teeth ought to be drawn which by their irregular figure and position lacerate the gums and lips, and cannot be brought into shape by the file. And lastly, it is sometimes necessary to draw a tooth for the curing a fistula, or ulceration of the gums near the roots of the teeth.

The regular method of drawing them is this: if the tooth is in the lower jaw, the patient must be seated on a low seat, or on the floor, and if in the upper jaw, he must be placed on a high stool or table; then the proper instrument is to be selected, and the tooth carefully drawn as a nail out of a piece of wood. But this must never be done while the gums are inflamed, swelled, or otherwise distempered.

TOP of a Ship, a round frame of boards lying upon the cross-trees near the head of the mast; here they furl and loose the top-sail, &c.

TOP-ARMOURS in a Ship of War, are a kind of cloths hung about the round-tops of the masts for shew; and also to hide the men which are on top in a fight, who lie there to sling stink-pots, &c. or to fire small shot down on the enemy, in case of boarding.

TOP-MASTS of a Ship, are four, which are made fast and settled unto the heads of the main-mast, fore-mast, mizzen-mast, and bow-sprit respectively.

TOP-GALLANT-MASTS of a Ship, are two, viz. main-top-gallant-mast and fore-top-gallant-mast, which are small round pieces of timber, set on their respective top-masts; on the top of which masts are set the flag-staffs, on which the colours, as flags, pendants, &c. hang.

TOP-ROPES of a Ship, are those with which the top-masts are set or struck; they are received through a great block which is seized on one side under the cap, and then are reeved through the heel of the top-mast, where is a brass shiver placed athwart ships; after this they are brought up and fastened on either side the cap with a ring: the other part of them comes down by the ties, and so is reeved into the knight-head; and, when it is to be heaved, it is brought to the capstan. These top-ropes belong only to the main and fore-mast.

TOP-SAILS and TOP-GALLANT-SAILS of a Ship, are those belonging to the top-masts and top-gallant-masts.

TOP, A-STARBOARD, on board a ship, a word of command to hale upon the larboard list.

TOP the Yard-arms, on board a ship, a word of command to make the yards hang higher or lower.

TOPARCHY, a little state or seignior, consisting only of a few cities or towns; or a petty country, governed and possessed by a toparch or lord.

TOPAZ, in natural history, a gem called by the ancients chrysolite, as being of a gold-colour.

The topaz, when perfect and free from blemishes, is a very beautiful and valuable gem; it is, however, very rare in this state. It is of the number of those gems which are found only in the round or pebble form, there never having been yet seen a true and genuine topaz of a columnar figure, though the far greater part of what our jewellers call such, are in that form. The greatest part of the true topazes are no larger than grains of a coarse seed; among these there are, however, some met with of the size of a pea, and some much larger; those are very rare.

It

It is of a roundish or oblong figure in its native or rough state, and usually is flatted on one side, and is generally of a bright and naturally polished surface, tolerably transparent. They are ever of a fine yellow colour; but they have this, like the other gems, in several different degrees: the finest of all are of a true and perfect gold-colour; but there are some much deeper, and others extremely pale, so as to appear scarce tinged.

The oriental topaz is equal to the ruby in hardness, and is second only to the diamond in lustre. The topazes of the other parts of the world fall off greatly from this hardness, but the purest of the genuine ones are considerably harder than crystal.

The topaz, on being thrown into a charcoal fire, entirely loses its colour, and when taken out, is a very fine colourless stone, undistinguishable from that known by the name of the white sapphire: upon the whole it appears, that the oriental coloured gems are all much alike in their matter, differing scarce at all, except in colour, and that when they are found either naturally colourless, or rendered so by art, it is not easy to distinguish one of them from the other.

The finest topazes in the world are found in the East-Indies, but they are very rare there of any great size: the Great Mogul, however, at this time, possesses one, which is said to weigh 157 carats, and to be worth more than 20,000*l*. The topazes of Peru come next after these, in beauty and in value; the European are principally found in Silesia and Bohemia, and are generally full of cracks and flaws, and of a brownish yellow.

Besides all these degrees of value in the genuine topazes, our jewellers keep what they call a kind of them, inferior greatly to the true ones; all these are common hexangular crystals, coloured to a paler or deeper yellow in mines: these they cut into stones for rings, and sell under the name of topazes; and most of the stones we see under that name are such.

The ancients have said much of the topaz's virtue: it is said to be a high cordial and sudorific, and to have been given also in hæmorrhages with great success. But whatever virtues it may possess, we are not to expect to find them in the stones our druggists now keep under the name of topazes, these being no other than fragments of a yellowish plated spar, common in lead mines, and impregnated more or less with that metal.

The topaz itself seems to owe its colour to lead, but the quantity it contains of that is so very inconsiderable, that it can be of no effect in the body, and may very well be supposed to leave it in the state of crystal; which seems as much as we are to imagine really of any of the gems; but this spar, sold in the place of topaz, not only discovers that it holds a great deal of lead by its weight, but lead has actually been separated from it, in no less quantity than one fifth of its weight.

TOPHUS, in medicine, denotes a chalky or stony concretion in any part of the body, as the bladder, kidneys, &c. but especially in the joints.

TOPIC, in rhetoric, denotes a probable argument, drawn from the several circumstances of a fact, &c. Hence the art of finding and managing such arguments, is called by the ancients *topica*, *τοπικη*.

TOPICS, or TOPICAL MEDICINES, are the same with external ones, or those applied outwardly to some diseased and painful part: such are plasters, cataplasms, unguents, &c.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, manor or tenement, field, garden, house, castle, or the like; such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORCH, *Teda*, a luminary used in several church-ceremonies, funerals, &c. and more usually called a flambeau.

TORCULAR, in surgery, the same with the tourniquet. See *TOURNEQUET*.

TORDYLIUM, in botany, a genus of plants, the flower of which is umbellated; and the principal umbel is composed of many small ones, compounded of many rays; the involucre of the greater umbel is composed of narrow leaves, as long as the rays of the umbel; those

of the rays are half the length; the umbels are deformed; the flowers have five heart-shaped inflexed petals, which are equal; they have each five hair-like stamina terminated by single summits, and a roundish germen, situated under the flower, supporting two small styles crowned by obtuse stigmas. The germen afterward turn to a roundish compressed fruit longitudinally indented, dividing in two parts, each containing one roundish compressed seed with an indented border.

Mr. Miller enumerates eight sorts of this plant, and says, they may be all termed annual, because they do not live more than one year; but some of them are called biennial, from the young plants which come up in autumn, lying through the winter, and producing their flowers and fruits the following summer; but, as the seeds which are sown, or permitted to scatter, perfect their seeds in the compass of one year, they should be termed annual; for this is the property of many of the plants with umbellated flowers, whose seeds should be sown in autumn, otherwise, if they come up, which frequently does not happen the same year when they are sown in the spring, the plants generally decay before their seeds ripen; but, as their whole growth is performed within the year, they should be esteemed as annual plants.

They are propagated by seeds, which should be sown in autumn soon after they are ripe, when the plants will soon appear, and are very hardy, so that they require no further care, but to keep them clear from weeds; and where they come up too close together, they should be thinned so as to leave them six inches asunder. In June following the plants will flower, and their seeds will ripen in autumn, which, if permitted to scatter on the ground, will produce a supply of plants without any trouble. These plants will grow on any soil or situation, so may be put into any obscure part of the garden.

TORRE, *Torus*, in architecture, a large round moulding, used in the bases of columns.

TORCUMATOGRAPHY, a Greek term, signifying the knowledge or rather description of ancient sculptures and basso-relievos.

TOREUTICE, *τορευτική*, that part of sculpture otherwise called turning.

TORIES, or TORYS, in the history of England, a faction or party opposed to the whigs.

The tories are great sticklers for the prerogative of the crown, as the whigs are for the liberties and privileges of the people: though, in truth, the principles of the moderate people of both parties do not greatly differ.

TORMENTIL, in botany, a genus of plants, with a rosaceous flower, consisting of four obversely cordated, plane, and patent petals; the stamina are sixteen subulated filaments, about half the length of the cup; the seeds are eight in number, oblong, obtusely acuminate, and contained in the cup, which forms a kind of globose capsule.

Tormentil-root has an austere styptic taste, accompanied with an aromatic flavour: it is one of the most agreeable and efficacious vegetable astringents: there are also a tincture and a distilled water of it, the former of which possesses all the virtues of the simple.

TORMINA, in medicine, a term sometimes used to express pain in general, but more particularly a species of pain called tormina ventris, or alvi, in English the gripes.

TORNADO, or TURNADO, a sudden and violent gust of wind from all points of the compass, frequent on the coast of Guinea.

TORPEDO, in natural history, a sea fish, famed, both among the ancient and modern naturalists, for a remarkable numbness wherewith it strikes the arm of those that touch it.

The torpedo is a flat fish, much resembling the thorn-back; sufficiently described in most treatises of fishes, and commonly found among the coasts of Provence, Gascony, &c. where the people eat it without danger.

Upon touching the torpedo with the finger, it frequently, though not always happens, that the person feels an unusual painful numbness, which suddenly seizes the arm up to the elbow, and, sometimes, to the very shoulder or head.

The pain is of a very particular species, and not to be described by any words: yet Messieurs Lorenzini,

Borelli, Redi, and Reaumur, who all felt it severely, observe it to bear some resemblance to that painful sensation felt in the arm, upon striking the elbow violently against a hard body: though, M. Reaumur assures us, this gives but a very faint idea of it.

Its chief force is at the instant it begins; it lasts but a few moments, and then vanishes entirely. If a man do not actually touch the torpedo, how near soever he holds his hand, he feels nothing: if he touch it with a stick, he feels a faint effect: if he feels it through the interposition of any pretty thin body, the numbness is felt very considerably; if the hand be pressed very strong against it, the numbness is the less, but still strong enough to oblige a man speedily to let go.

M. Reaumur accounts for the phenomena of the torpedo in this manner:—The torpedo, like other flat fishes, is not absolutely flat, but its back, or rather, all the upper part of its body, a little convex: when it did not, or would not produce any numbness in such as touched it, its back, he found, always preserved its natural convexity; but whenever it would dispose itself to resent a touch or thrust, it gradually diminished the convexity of the back parts of the body; sometimes only rendering them flat, and sometimes even concave.

The very next moment the numbness always begins to seize the arm; the fingers that touched, were obliged to give back, and all the flat and concave part of the body was again seen convex: and whereas it only became flat insensibly, it returned to its convexity so swiftly, that one could not perceive any passage from the one to the other state.

The motion of the ball out of a musket is not, perhaps, much quicker than that of the fish re-assuming its situation; at least, the one is not more perceivable than the other.—It is from this sudden stroke that the numbness of the arm arises, and accordingly the person, when he begins to feel it, imagines that his fingers have been violently struck. It is the mere velocity of the stroke that produces the numbness.

The wonder is, how so soft a substance as that of the fish should give so rude a blow: indeed, a single stroke of a soft body could never have done it, but, in this case, there is an infinity of such strokes given in an instant.

To explain the admirable mechanism thereof, we must give a view of the parts whereon it depends.—This mechanism then, depending, consists in two very singular muscles described by several authors who have given the anatomy of the torpedo. Redi, and after him Lorenzini, call them the muscoli falcati; their form is that of crescents, and they, together, take up almost half the back of the fish, the one on the right side, and the other on the left. Their origin is a little above the mouth, and they are separated from each other by the bronchia, into the last of which they have their insertions.—What is singular in them is their fibres, if, with the authors above-mentioned, we may give that name to a sort of smaller muscles as big as goose quills, of an assemblage of which the two great muscles are formed. These lesser muscles are hollow cylinders, their length nearly equal to the thickness of the fish, and ranged aside of each other; all perpendicular to the upper and lower surfaces of the fish, accounting these surfaces as two nearly parallel planes. The exterior surface of each of these cylinders consists of whitish fibres, whose direction is the same with that of the cylinder: but these fibres only form a kind of tube, whose parietes are not above the thickness of a leaf of paper. The cavity of the tube is full of a soft matter, of the colour and consistence of pap, divided into twenty-five or thirty different little masses, by so many partitions, parallel to the base of the cylinder; which partitions are formed of transverse fibres: so that the whole cylinder is, in some measure, composed of twenty-five or thirty smaller cylinders placed over each other, and each full of a medullary substance.

We need only now remember, that when the torpedo is ready to strike its numbness, it slowly flattens the outer surface of its upper part, and the whole mechanism whereon its force depends will be apparent. By that gradual contraction it bends, as it were, all its springs; renders all its cylinders shorter, and at the same time, aug-

ments their basis; or, which amounts to the same, stretches all the little inclosures which divide the soft matter. In all probability too, the large fibres, or little muscles, in that moment lose their cylindrical form, to fill the vacuities between them.

The contraction being made to a certain degree, all the springs unbend, the longitudinal fibres are lengthened, the transverse ones, or those which form the inclosures, are shortened; each inclosure, drawn by the longitudinal fibres which are lengthened, drives the soft matter it contains upwards, in which it is apparently assisted by the undulatory motion which is in the transverse fibres, when contracting.

If then a finger touch the torpedo, it instantly receives a stroke, or, rather, several successive strokes from each of the cylinders wherein it is applied. As the soft matter is distributed into divers inclosures, it is more than probable all the strokes are not given precisely at the same moment: nay, were there no inclosures to separate the matter, its impresseure would give strokes, in some measure, successive; for all parts of soft bodies do not strike at once; the impression of the last does not take till after the first have done acting. But these several inclosures serve to augment the number of the springs, and, of consequence, the velocity, and force of the action. These quick re-iterated strokes given by a softish matter, shake the nerves, suspend or change the course of the animal spirits, or some fluid equivalent: or, if you had rather, these strokes produce an undulatory motion in the fibres of the nerves, which clashes or disagrees with that they should have in order to move the arm; and hence the inability we are under of using the same, and the painful sensation which accompanies it.—Hence it is, that the torpedo does not convey its numbness to any degree, except when touched on these great muscles; so that the fish is very safely taken by the tail, which is the part by which the fishermen catch it.

The authors who have accounted for the effect of the torpedo from torporific effluvia, have been obliged to have recourse to the same two muscles; but then they only make them reservoirs of the corpuscles by which the numbness is effected. Lorenzini, who has observed the contraction, as well as Reaumur, pretends, all its use is to express those corpuscles from out of the hollow fibres of those muscles wherein they are imprisoned; but this emanation of corpuscles, admitted by most authors, is disapproved by Mr. Reaumur, from the following considerations.

1. Because no numbness is conveyed, if the hand be at the smallest distance from the torpedo: now, to use their own comparison, if the torpedo numbs as the fire warms, the hands would be affected at a distance from the one, as well as the other.

2. Because the numbness is not felt till the contraction of the muscles is over; whereas, were the cause in torporific particles expressed by the contraction, the effect would be felt in the time of contraction.

3. Because, were the numbness the effect of torporific particles, it would be conveyed by degrees, as the hand warms by degrees.

Lastly, because the torpedo conveys its numbness to the hand through a hard solid body, but does not do it through the air. Were the only use the torpedo makes of its faculty the saving itself from the fishermen, as some have supposed, it would signify but little; for it is very rare that it escapes their hands. Pliny, Aristotle, and most naturalists, therefore, agree, that it likewise serves it for the catching other fishes, and that it is generally found on banks of sand, &c. probably to serve it as a foundation, or support, for the exerting its faculty. M. Reaumur had no fishes alive, to see what the torpedo would do to them; but an animal, next a-kin to a fish, he tried it on, viz. a drake, which being shut up a while in water with the fish, was taken out dead; doubtless, from its too frequent contacts on the torpedo.

M. Du Hamel, in his History of the Academy of Sciences anno 1677, mentions a kind of torpedo's, which he compares to conger eels. M. Richer, from whom he has the account, affirms, on his knowledge, that they numb the arm strongly, when touched with a staff, and that

that their effects even produce vertigo's. See (plate CXXXI. fig. 3.)

TORQUE, in heraldry, denotes a round roll of cloth, twisted and stuffed: such as the bandage, frequently seen in armories, about the heads of Moors, &c. It is always of the two principal colours of the coat; and is accounted the least honourable decoration worn on the helmet, by way of crest.

TORREFACTION, in chemistry, is the roasting or scorching of a body by the fire, in order to discharge a part either unnecessary or hurtful in another operation; as sulphur is thus discharged from an ore, before the metal can be obtained to advantage.

TORRENT, *Torrents*, in geography, denotes a temporary stream of water, falling suddenly from mountains, whereon there have been great rains, or an extraordinary thaw of snow.

TORRICELLIAN, a term very frequent among physical writers, used in the phrases, Torricellian tube and Torricellian experiment, on account of the inventor, Torricelli, a disciple of the great Galileo.

TORRID ZONE, among geographers denotes the tract of earth lying under the line, and extending on each side to the two tropics, or to 23 degrees and a half of latitude.

The ancients believed the torrid zone uninhabitable; but from the late navigations we learn, that the excessive heat of the day there is tempered by the coldness of the night.

TORT, in law, a French term signifying wrong or injury.

TORTOISE-SHELL, the shell, or rather, scales of a testaceous animal, called a tortoise; used in inlaying, and in various other works, as for snuff-boxes, combs, &c.

The best tortoise shell is thick, clear, transparent, of the colour of antimony, sprinkled with brown and white: when used in marquetry, &c. the workmen give it what colour they please, by means of coloured leaves which they put underneath it. See the article **TESTUDO**.

TORTURE, a grievous pain inflicted on a criminal, or person accused, to make him confess the truth.

TOTTED. A good debt to the king is, by the foreign opposer, or other officer of the exchequer, noted for such by writing the word *tot*, *q. d. tot pecunie regi debentur*; whence it is said to be totted. Also that which is paid is to be totted.

TOUCAN, in ornithology, a species of ramphastos, of a middle size between our common magpie and the thrush, but having a beak thicker and longer than its whole body: this beak is hooked at the end, and is of a very thin substance, not exceeding the thickness of a membrane, and very light and hollow, yet bony in substance, and very bright and shining. It has a sort of toothed edge, which prevents its shutting closely, and, giving passage for the air, enables the bird to live without nostrils. It is yellowish on the outside and red within, and is covered with a sort of scaly substance, easily scraped off with a finger at the edge.

The head of this bird is large in proportion to its body, and is black on the crown; the rest of it, and the neck and back, are slightly variegated with white; its breast is of a bright orange colour, its belly and thighs of a very fine and bright red, and the tail is black but red at the end.

TOUCAN, in astronomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called *Anser Americanus*.

TOUCH-HOLE, or vent in gunnery, is the small hole at the end of the cylinder of a gun or musquet, by which the fire is conveyed to the powder in the chamber. In a firelock, carabine or pistol, it is called the touch-hole, but in a piece of cannon it is more properly called the vent.

TOUCH-NEEDLES, small masses of gold, silver, and copper, each pure and simple, and, in all the different combinations, proportions, and degrees of mixture, prepared for the trying gold and silver by the touch-stone, by comparison with the mark they leave on it.

The metals usually tried by the touch-stone, are gold, silver and copper, either pure, or mixed with one another in different degrees, and proportions, by fusion. In order to find out the purity, or quantity of baser metal in these various admixtures, when they are to be examined; they are compared with these needles, which are mixed in a known proportion, and prepared for this use. The metals of these needles, both pure and mixed, are all made into laminæ or plates one twelfth of an inch broad, and of a fourth part of their breadth in thickness, and an inch and half long; these being thus prepared, you are to engrave on each a mark indicating its purity, or the nature and quantity of the admixture in it.

The manner of making the touch-needles is by the proportions of the mark, a weight of half a pound, or eight ounces, being divided into sixteen half ounces, the half ounces each into four drachms, the drachm into four penny-weights, and this into two half penny-weights.

Silver TOUCH-NEEDLES, these must be only tempered with copper, and the proportion determined by the mark divided into half ounces and grains.

You must use therefore for this purpose, one mark of such a weight that it may constitute a sufficient mass of metal for the making one needle, let it weigh for instance one drachm, then weigh such a mark of the purest silver, wrap it up in a small paper, and upon this write sixteen half ounces, which will signify that the whole mark of this metal is the purest silver; make the first needle of this mass.

Next weigh fifteen half ounces of pure silver, and one half ounce of pure copper; wrap these both in a paper, and write on it fifteen half ounces, which will signify that there are in that small mass fifteen parts of pure silver, and one part of pure copper: make of this the second needle. In the same manner go on with the rest, add two half ounces of copper to fourteen half ounces of silver, mark it fourteen half ounces, make the third needle of this, and in the same manner proportion the small masses of silver and copper for making the other needles, and put inscriptions upon every one in the following manner:

1. — 16	0
2. — 15	1
3. — 14	2
4. — 13	3
5. — 12	4
6. — 11	5
7. — 10	6
8. — 9	7
9. — 8	8
10. — 7	9
11. — 6	10
12. — 5	11
13. — 4	12
14. — 3	13
15. — 2	14
16. — 1	15

For the needle half oz. of silver half oz. of copper.

When you have gone thus far, and have the metals in each of these proportions, wrapped up in its separate paper; put each separately into a new crucible never used for any operation, and adding a little borax melt them together in a very quick fire, which must be well kindled before with bellows; or what is yet better, throw them suddenly into a hot crucible, and, as soon as they melt, stir them with a dry wooden peg, burnt at the end, and pour them immediately into an ingot.

When this is done, wrap up each mass, when cold, in its own paper again, and weigh them singly, in a nice balance. If they still weigh a whole mark they are good; but, if there is any considerable deficiency in their weight, it is a sign that your fire having been of too weak, or of too long duration has consumed as much copper as is wanting in the weight: therefore this mass must be esteemed useless, and another made in its place in the same proportion.

When this is all finished, make with a hammer, out of each of these small masses, a needle, heating them a little; then engrave on each of these needles, the number of half ounces it contains, as before marked on its paper;

paper; that is, upon the first 16, upon the second 15, and so on, and then pierce them at one end, and, running a silver wire through their eyes, collect them in order according to their different numbers. These are the silver touch-needles, made of the different allays of silver and copper.

In Holland they make use of the mint mark, divided into grains, for the making their needles. The first needle made of pure silver is said to be of twelve penny-weights. The second is made of eleven penny-weights and eighteen grains, by the addition of six grains of copper. The third is made of eleven penny-weights and twelve grains, by the addition of twelve grains of copper; and so on, the proportion of silver decreasing always six grains, that is, one quarter of a penny-weight at a time, and that of the copper being always increased in the same proportion, till at last the weight of the silver is reduced to one penny-weight, and that of the copper increased to eleven penny-weights, which proportion constitutes the last needle.

It is needless, however, to go through the whole series of the needles, by so small progressions to the very last, for very delicate proportions cannot be very accurately distinguished in the operation.

Gold TOUCH-NEEDLES. These must be mixed either with silver alone, or with silver and copper, variously intermixed. This mixture is called allaying or carraacting, and is determined with a mark divided into carraacts or weights of two sixth parts of an ounce. There is nothing to be observed about the making of these needles, besides what has been already said in regard to the silver needles; except that the proportions of the weights are determined in another manner. These needles are made according to the following division and order; and they all weigh one mark.

The first is entirely of pure gold.

2. 23 Car. 6 Gr.	} pure gold	6 Gr.	} pure silver.
3. 23 Car.		1 Car.	
4. 22 Car. 6 Gr.		1 Car. 6 Gr.	
5. 22 Car.		2 Car.	
6. 21 Car. 6 Gr.		2 Car. 6 Gr.	
7. 21 Car.		3 Car.	
8. 20 Car. 6 Gr.		3 Car. 6 Gr.	
9. 20 Car.		4 Car.	
10. 19 Car.		5 Car.	
11. 18 Car.		6 Car.	

The decrease goes on thus, by whole carraacts, till the weight of the gold is arrived at one carraact, and that of the silver at twenty-three; for after the ninth needle you cannot make so exact a distinction of the half carraacts.

This mixture of gold and silver is called the white allay; but, when copper together with silver enters into the mixture of the gold, then it is called a mixed allay. The needles, for trial of pieces thus debased, are made of mixtures analogous to the former, except only that those portions which in the first case were pure silver, here consist of copper and silver mixed. Therefore you have a double series; for the mixture is either of two parts of silver, and one of copper, or of two parts of copper, and one of silver. For instance,

The first is of pure gold.

2. } of pure gold.	23 Car. 6 Gr.	} of pure silver.	4 Car.	} of pure copper.	2 G.
3. }	23 Car.		8 Gr.		4 G.
4. }	22 Car. 6 Gr.		1 Car.		6 G.
5. }	22 Car.		1 Car. 4 Gr.		8 G.
6. }	21 Car. 6 Gr.		1 Car. 8 Gr.		10 Gr.
7. }	21 Car.		2 Car.		1 Car.
8. }	20 Car. 6 Gr.		2 Car. 4 Gr.		1 Car. 2 Gr.

and so on as in the foregoing.

If in this table you take pure copper instead of pure silver, and silver instead of copper, this gives you a third series of golden needles. And you may have a fourth by mixing with gold equal quantities of silver and copper in the same proportion. These allays of gold are much in use, but workmen may easily employ a multitude of other variations, which, compared with the already mentioned, will be distinguished in a thousand

different ways by an experienced person, so that it is neither possible, nor necessary, to imitate them all.

But that these golden needles may not be too expensive, they may be made much shorter than those of silver, and afterwards soldered to plates of copper, that may be sufficiently long for use.

The use of these needles is by means of the touch-stone; and arises hence, that every metal when pure must have its specific colour, that distinguishes it from the rest: but, metals being the most opaque of all known bodies, the specific colour of every one appears most distinctly, when you rub it against a very black hard stone; and if the colours of two or more metals are expressed by large lively spots, made near each other on the same plane, by rubbing them against the surface of the stone, you will by that means easily discern their difference, or their likeness.

The stone adapted to this use, and called from its office the touch-stone, must have the following qualities. It must be of the deepest black, lest the tincture of the metal should be altered by spurious rays of light shining among it: it must be capable of being pretty well polished, for, when too rough, the colours of the metals rubbed against it cannot be neatly or regularly distinguished; and, if it is too smooth, the metals are but faintly, and too slowly abraded or scraped by it, especially when gold is tried. It must also be neither too hard, nor too soft. Tripoli, coal-dust, and tin-ashes are used in rubbing off the thin metalline crusts, and in a short time the stone, when very hard, is apt to acquire too smooth a surface; and, when it is too soft, it easily wears, throws off a dust, and contracts furrows.

The black rough marbles, and the softer black pebbles from the beds of rivers, are most proper for this use, and are to be made into the form of a quadrangular prism, about an inch thick, and two or three inches long.

The method of using your needles and the stone is this: when you meet with a piece of metal to be tried, first wipe it very well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an experienced person will in some degree judge before-hand what the principal metal is, and how, and with what debased. Then chuse a convenient not over large part of the surface of the metal, and rub it several times very hardly and strongly against the touch-stone, that, in case a deceitful coat or crust should have been laid upon it, it may be worn off by that friction. This however is done more readily by a grind-stone or small file, if you have them at hand. Then wipe a flat and very clean part of the touch-stone, and rub against it, over and over, the just mentioned part of the surface of the piece of metal, till you have on the flat surface of the stone a thin metallic crust, an inch long and about an eighth of an inch broad: this done, look out the needle that seems most like to the metal under trial, wipe the lower part of this needle very clean, and then rub it against the touch-stone as you did the metal by the side of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks, made by your needle, and the metal under trial; you may with great probability pronounce that metal, and your needle, to be of the same allay; which is immediately known by the mark engraved on your needle. But, if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried; chuse out another needle, either of a darker or a lighter colour than the former, as the difference of the tinge on the touch-stone directs; and by one or more trials of this kind you will be able to determine which of your needles the metal answers, and thence what allay it is of, by the mark of the needle; or else you will find that the allay is extraordinary, and not to be determined by the comparison of your needles.

But, if the metal under trial has been altered by tin, arsenic, zink, or other such admixtures, the workmen may be deceived by the colour, so as to take for pure gold, or silver, that which is not by any means such. Deceits of this kind, however, are found out by the assistance of acid menstrua. Aqua fortis answers this purpose, when the mass is of the colour of gold, and aqua-

PASSED ON THE 14TH
DAY OF MARCH 1904
RELATIVE TO THE
SASKATCHEWAN
RAILWAY COMMISSION
AND TO ADVISE YOU
THAT THE SAME HAS
BEEN FORWARDED TO
THE APPROPRIATE
DEPARTMENT FOR
CONSIDERATION
AND ACTION
Yours faithfully,
J. H. McLEOD,
Clerk of the Council.

Trepanning Instruments.

aqua-regia, when it is of the colour of silver; for the first of these menstrua dissolves all metals except gold, and the latter all metals except silver. In this case then you are to pour, upon your metallic streak on the stone, one small drop of either of these liquors, and extend it gently over it with a feather. If it is neither gold nor silver, the whole streak will be obliterated and consumed; but, if there is any gold or silver in it, this remains undissolved, and shews another colour, because the other parts have been separated from it by the solution. When these menstrua are used, great care must be taken that there is no oil in the way; for that would spoil and destroy their effects.

Besides these, the following particulars are to be observed: gold and silver when pure, whether separate or both mixed together, without the addition of any other matter, when made hot in the fire, not only preserve their colour, but, if they were tarnished before, they recover their splendor there, not losing the least part of their weight: and, by this quality in these two metals, the caratura alba, or white alloy, made by the mixture of gold and silver alone, is distinguished from all the others. If you have not liberty to try the whole mass in the fire, you may make this experiment on a small piece of it with a blow-pipe.

If you find a needle of the same alloy with the metal under trial, the streaks made by both upon the touch-stone must undergo exactly the same changes when aqua-fortis is poured on them; and this ought always to be made a part of the trial by the touch-needles, that no fraud may be at the bottom.

All gold rendered brittle, when compared with the touch-needles by the stone, will appear less pure than it really is; and on the contrary all silver rendered brittle has the whiteness of silver in a higher degree: nor is there any wonder in this, when rightly considered, since the bodies which make gold and silver brittle are only a few metals, and semi-metals, all of a very bright white colour, and necessarily adding to the whiteness of silver, and taking from the yellowness of gold; such are tin, lead, regulus of antimony, bismuth, zink, and arsenic. These dilute the yellow colour of gold or copper into a whiteness, so that the colour of copper mixed with the silver is hidden by admixtures of this kind, whereas gold on the contrary appears by them to have much more silver in it than it really has.

In a white alloy, aqua-fortis does not discover the presence of silver from twenty-three to seven carats, because aqua-fortis does not separate silver from gold, unless the mass contains three times more silver than gold.

Metallic streaks or crusts which have been left some time upon the touch-stone, cannot be compared with fresh ones, with any degree of use, because their remaining long on the stone always alters their colour.

Silver when tempered with brass appears whiter than it would do with a like quantity of copper, and, as it may then be rendered sufficiently ductile by a proper operation, you will hardly be able to find out the fraud with the touch-stone, unless you make a second time the same comparison with the streak of a needle of the same colour, having previously poured aqua-regia upon the metallic crust laid by rubbing on the touch-stone; nor are touch-needles, tempered with brass, of any great use on this occasion, since this artificial metal is sometimes more and sometimes less yellow.

TOUCH-STONE, a black, smooth, glossy stone used to try metals upon.

The ancients called it *lapis Lydius*, the Lydian stone, from Lydia, a country of Asia Minor, whence it was brought.

The moderns call it touch-stone, in regard the proof they make of metals, chiefly silver, is, by touching or rubbing the metal to be tried on the stone, and comparing the colour of the mark it leaves thereon, with the mark of another piece of metal of the same species, whose goodness is past doubt.

The Irish touch-stone, called *bassanus Hibernicus* by Molyneux, and some others, is a black marble found in the county of Antrim in that kingdom, in angular columns, forming that amazing pile called by the vulgar the Giant's Causeway.

This marble has the property of trying metals by the touch beyond any other known stone; but it is not easily wrought into form, being so hard that it turns the edges of all the tools used to cut stones. Were it not for this, it is admirably calculated for building, and for ornamental works; but nobody has attempted to use it in this manner, any where, except in the church of Ballywellan in the neighbourhood; and here the trouble of cutting is avoided, for the joints are taken as they found them, and the church is built of these in their natural shape, piled one upon another. The outer surface of this stone is of a whitish colour like lime-stone, but this is only the effect of the weather upon it; for wherever it is broken it is found to be of a fine iron grey, and when polished appears of a true and deep jetty black.

TOUR, a French term, frequently used for a journey or progress through one or more countries.

TOURNAMENT, or **TURNAMENT**. See **TURNAMENT**.

TOURNEFORTIA, in botany, a genus of plants; the empalement of the flower is permanent, of one leaf, cut into five small segments at the top. The flower is of one petal, of the globular bell shape, cut at the brim into five acute points, which spread openly horizontally; it has five awl-shaped stamina the length of the tube, terminated by single summits, and a globose germen supporting a single style the length of the stamina, crowned by a single stigma. The germen afterward becomes a spherical succulent berry, inclosing four oblong oval seeds, resting upon the empalement.

Mr. Miller enumerates eight sorts of this plant, natives both of the West Indies, and of New Spain; and may be all propagated by seeds or cuttings. If by seeds, they must be procured from the countries where they grow naturally; these should be sown in small pots filled with light earth, and plunged into a hot-bed of tanners bark. These seeds sometimes grow the first year, but they often remain in the ground a whole year; therefore, if the plants should not come up the same season, the pots should be plunged in autumn into the tan-bed in the stove, where they should remain all the winter; and in the spring they should be removed out, and plunged into a fresh tan-bed, which will soon bring up the plants, if the seeds were good. When these are fit to remove, they should be each planted in a small pot, and plunged into a tan-bed, where they must be shaded from the sun till they have taken new root; and then they must be treated in the same way as other tender plants from the same countries, which require to be kept in the bark stove. The plants raised from cuttings must be treated in the same way.

TOURNEQUET, in surgery, an instrument made of rollers, compresses, screws, &c. for compressing any wounded part, so as to stop hæmorrhages.

The common tournequet is very simple, consisting only of a roller, which, with the help of a small stick, serves to stop the effusion of blood from large arteries, in amputations, by forcibly tying up the limb. The things necessary for this are a roller, of a thumb's breadth, and of an ell in length, a small cylindrical stick, a conglomerated bandage, two fingers thick and four long, some compresses of a good length and about three or four fingers breadth, to surround the legs and arms, and a square piece of strong paper or leather, about four fingers wide. See plate CXXXI. fig. 4.

The manner of applying this instrument is thus; the rolled bandage is to be applied to the trunk of the wounded artery length ways, covering it, in a contrary direction, with compresses surrounding the foot, leg or arm, as it were with a ring; the roller must be passed twice round these applications and fastened in a knot, but so loosely that you may easily introduce your hand between it and the part: the leather or thick paper must now be nicely placed under it, upon the external part of the leg, and the roller tightened by degrees, by turning round the stick, which is to be introduced into the knot; this to be done till the hæmorrhage is entirely stopped: the stick must now be kept in this situation till the wound is properly treated, and the return of the hæmorrhage is prevented.

When this end is acquired, the tournequet is to be loosened, or entirely taken off, as shall be judged most convenient; but where it is applied to the arm, the rolled bandage is to be placed near the axilla, in the internal part of the humerus, and the stick in this case is to be fastened on the opposite side, the situation of the artery there requiring this position: and when it is to be applied to the thighs, the bandage is to be put as the case shall require, either to the upper part of the thigh, or just over the knee.

But besides the common tournequet, there are other more complex forms of this instrument. *Fig. 5.* is a brass tournequet, for stopping the hæmorrhages in wounds of large arteries: where A A is a brass plate, somewhat bent; B B, a strong brass screw; C, a round plate, to be fixed upon the wound; D, the button which turns the screw; E E, a strong leather belt, to surround the wounded part; F F, part of the belt pierced with holes, whereby it may be fixed upon the belt G G, and lengthened and shortened according to the size of the limb.

Fig. 6. is another brass tournequet, after Petit's manner, the use and application of which will be easily understood from the description of *fig. 5.*

In *fig. 7.* is delineated a wooden tournequet, where A A is the upper part; B B, the lower part; C, the screw; D, the two small iron screws, to which a leather or silk belt is to be fixed; E, hooks, on which to fasten the other end of the belt; F F, the ends of the upper and lower parts of the instrument, hollowed to receive the belt, and keep it steady in its situation.

Fig. 8. Is another kind of tournequet, made of iron, the parts and uses of which will be easily conceived from what has been already said.

TOWAGE, the hawling or drawing of a ship, barge, &c. by men or beasts, or by another ship or boat, fastened to her, in order to make her enter a port, ascend a river, &c.

TOWER, *Turris*, a tall building, consisting of several stories, usually of a round form, though sometimes square or polygonal.

Towers are built for fortresses, prisons, &c. as the Tower of London, the Tower of the Bastile, &c.

The Tower of London is not only a citadel, to defend and command the city, river, &c. but also a royal palace, where our kings, with their courts, have sometimes lodged; a royal arsenal, wherein are arms and ammunition for sixty thousand soldiers; a treasury for the jewels and ornaments of the crown; a mint for coining of money; the great archive, wherein are preserved all the antient records of the courts of Westminster, &c. and the chief prison for state criminals.

TOWN, a place inhabited by a considerable number of people, being of a middle size between a city and village.

TOXICODENDRON, Poison-tree, in botany, a tree the male flowers of which are upon different plants from the female; they have a small empalement, cut into five points at the brim, but have no petals; they have five short stamina, terminated by roundish summits. The female flowers have empalements like the male; they have no stamina, but in the center is situated a roundish germen, supporting three small styles, crowned with globular stigmas. The germen afterwards turns to a berry with one or two cells, inclosing one seed in each.

Mr. Miller enumerates nine species of the poison-tree, all possessed of the same poisonous quality.

The first sort grows naturally in most parts of North-America; it has a low shrubby stalk, which seldom rises more than three or four feet high, sending out shoots near the bottom, which trail upon the ground, putting out roots from their joints, whereby it multiplies and spreads greatly; so that when it is not confined, or trained up to a support, the stalks seldom rise upward. If the stalks happen to be close to a wall, they emit roots which fasten to the joints in the wall, and support themselves when they are severed from the root; and the stalks of such plants will become more ligneous, and rise much higher, than those which grow in the ground. The foot-stalks of the leaves are near a foot long; the leaves are composed of three smooth, oval heart shaped lobes, which are entire. The flowers come

out from the side of the stalk in loose panicles, of an herbaceous colour, and small, so make no great appearance. Some plants have only male flowers with five stamina in each; these decay without producing fruit; but upon other plants they are only female flowers, which have a germen and three very short styles; these are succeeded by roundish, channelled, smooth berries, of a yellowish grey colour, which inclose one or two seeds.

This plant, when once planted in a garden, will propagate fast enough by its trailing branches, which put out roots at every part. It will thrive in almost any soil or situation.

The second sort grows naturally in most parts of North America. The stalks of this rise higher than those of the former; the branches are slender, but ligneous; they have a brown bark, and are garnished with downy leaves, standing upon pretty long foot-stalks, composed of three oval lobes, indented angularly, and hoary on their under side. The male flowers, which are produced on separate plants from the fruit, come out from the side of the stalks in close short spikes; these are of an herbaceous colour, and have five short stamina in each. The female flowers are produced in loose panicles; these are in shape and colour like the male, but larger, and have a roundish germen, supporting three very short styles, and are succeeded by roundish berries, which ripen in autumn.

The third sort grows naturally in North America; this has a shrubby, erect, branching stalk, which rises six or seven feet high, covered with a brown bark, garnished with smooth trifoliate leaves, whose lobes are oval, spear-shaped, and have a few sinuated indentures on their borders. The male and female flowers grow upon separate plants; their shape and colour like those of the former, and the fruit is also like that.

The fourth sort grows naturally in Virginia, Pennsylvania, New England, and Carolina; from all these countries I have received seeds: it also grows in Japan. This, in the countries where it grows naturally, rises with a strong woody stalk to the height of twenty feet or upward; but in England we seldom see any of them more than five or six; the reason of this is from the plants being tender, so are destroyed in severe winters; but I have seen some plants, which were kept in pots and sheltered in winter, upward of ten feet high, in the garden of Samuel Reynardson, Esq; at Hillendon, which, after his death, were purchased with all his other exotic plants by Sir Robert Walpole. This has a strong woody stalk, covered with a light brown bark, inclining to grey. The branches are garnished with winged leaves, composed of three or four pair of lobes, terminated by an odd one. The lobes vary greatly in their shape, but for the most part they are oval and spear-shaped; they are sometimes rounded at their base, but generally end in acute points; their upper surface is smooth, of a lucid green, but their under side is pale, and a little hairy. The foot-stalks of the leaves change to a bright purple colour toward the latter part of the summer, and in autumn all the leaves are of a beautiful purple colour before they fall off. The male flowers are produced upon loose panicles from the wings of the branches; they are small, of an herbaceous white colour, composed of five small roundish petals, and have five short stamina within, terminated by roundish summits. The female flowers are upon separate plants from the male, and are disposed on loose panicles; these are shaped like the male, but are somewhat larger, and have in their center a roundish germen, supporting three very short styles, crowned with globular stigmas. The germen afterward turns to a berry, variable in shape, sometimes almost oval, at others shaped like a small spear; but the most general form is roundish, with a protuberance almost like the cicer; these include one seed. It flowers in July, and in warm seasons the female plants produce fruit, but they seldom ripen here.

This is undoubtedly the same plant which is mentioned by Dr. Kempfer in his *Amœnitates Exoticarum*, by the title of *Sitz vel Sitz Adju*, or *Arbor vernicifera legitima*, *folio pinnato juglandis*, *fructu racemosa Ciceris facie*. *Fasc. v. p. 791, 792.* The true varnish tree, with a walnut tree leaf, and a branching fruit like cicers. But the figure

figure he has exhibited of it, is the most inaccurate of any perhaps to be found in any of the modern books of botany. It is drawn from a side shoot of a branch which has been cut off, so has neither flower or fruit to it, and being a vigorous shoot, the leaves are very different in size and shape from those on plants which have not been headed; and his description of the leaves seems to have been taken from this branch, otherwise he could not have compared them to those of the walnut-tree. He seems to have been conscious of this fault, by his adding another figure of the plant in small under his own; taken from a Japan herbal, in which there is a much better representation of it than his own conveys. How a person who was employing himself in making drawings of plants in a country, where the natural history of it was so little known, should make choice of such an imperfect sample for his figure, is amazing, for there can be no doubt of his meeting with perfect plants in flower or in fruit, in a place where the shrubs are cultivated so plentifully as he mentions; and in his description of it, he sets out by comparing the height of the shrubs to those of willow, than which he could not have chosen any plant by way of comparison, which would have conveyed a more indetermined idea; for it is well known there are different species of willow, whose growth is from four to forty feet high; therefore there can be no other way of reconciling his description with what he afterward mentions, unless when he is giving an account of the method used by the natives in collecting the varnish; where he says the shrubs are cut down every third year, but by comparing their growth with that of the willows, which are cut down for fuel, &c. every four or five years.

However, as the dried samples of the plant which he brought over, agree with the American Toxicodendron, and the milky juice of both have the same qualities of staining, so there can be no doubt of the plants being the same; therefore if it is thought that varnish may be of public utility, it may be collected in plenty in most of the English settlements in North America.

Kempfer has also given a figure and description of a spurious varnish tree, which is called Fasi-no-Ki by the natives, and is by him titled, *Arbor vernicifera spuria*, *Sylvestris angustifolia*; spurious wild varnish-tree with a narrow leaf, which he says agrees with the other in every part, excepting the lobes of the leaves, which are narrower. This led me into a mistake in the former editions of the Gardener's Dictionary, by supposing their difference might arise from culture only; but having since raised from seeds a shrub which has all the appearance of his spurious varnish-tree, and is evidently a distinct species, if not of a different genus from the true sort, I am certain Kempfer has been guilty of a great mistake in this particular. The seeds of this were sent from China, for those of the varnish-tree; but when I sowed them, I remarked they were pretty much shaped like those of the beech-tree, but smaller; being thick on one side and slender on the other, in shape of a wedge, from whence I supposed there were three of the seeds included in one capsule. There is a shrub of this kind now growing in the Chelsea garden, which is more than fifteen feet high; but, as it has not yet produced flowers, I am at a loss where to range it.

The fifth sort grows naturally in North America, from whence the seeds were a few years since brought to England. This has a shrubby stalk, which sends out many ligneous branches, covered with a smooth purple bark, garnished with smooth trifoliate leaves, standing upon foot stalks an inch long; the lobes are oval, of a deep lucid green on their upper side, but of a pale green on their under, deeply crenated or indented on their edges, their base joining close to the foot-stalks. The leaves, when bruised, emit an odour like that of orange peel, from whence the gardeners have titled it the sweet-scented toxicodendron. The male flowers are produced in short close panicles; they are small, of an herbaceous white colour; they are upon separate plants from the fruit, which grow in sparfed panicles, and are of an oval shape.

The sixth sort grows naturally in North America. The stalks of this sort emit roots their whole length, whereby they fasten to trees or any neighbouring sup-

port, and climb to the height of six or eight feet, garnished with trifoliate oval leaves, which are smooth, and cut into sinuses on their edges. The flowers are produced in short panicles from the side of the branches; they are male and female on different plants like the other species.

The seventh sort was sent me by Mr. John Bartram from Philadelphia, by the title of great toxicodendron; this hath trailing roots, which run near the surface of the ground, sending up stalks in different places; the leaves stand upon long foot-stalks, composed of three or four obtuse rough lobes, sawed on their edges.

The first, sixth, and seventh sorts propagate in plenty by their creeping stalks and roots; the others are propagated by laying down their branches, which will put out roots in one year, and may then be taken off and transplanted, either in the places where they are to remain, or in a nursery to grow two or three years, to get strength before they are planted out for good; they may also be propagated by seeds, which should be sown on a bed of light earth, and when the plants come up, they must be kept clean from weeds the following summer; and before the frost comes on in autumn, the bed should be hooped over, that the plants may be covered with mats, for otherwise the early frosts will kill their tops, which frequently causes their stalks to decay to the ground; for as the young plants are tender, and generally shoot late the first year, they are in much greater danger than when they get more strength. In spring the plants may be transplanted into nursery-beds to grow a year or two, and may then be transplanted for good.

These plants are preserved by the curious in botany, for the sake of variety; but as there is little beauty in them, there are not many of the sorts cultivated in England. The wood of these trees, when burnt, emits a noxious fume, which will suffocate animals when they are shut up in a room where it is burnt: an instance of this is mentioned in the Philosophical Transactions by Dr. William Sherard, which was communicated to him in a letter from New England by Mr. More, in which he mentions some people who had cut some of this wood for fuel, which they were burning, and in a short time they lost the use of their limbs, and became stupid; so that if a neighbour had not accidentally opened the door, and seen them in that condition, it is generally believed they would soon have perished. This should caution people from making use of this wood for such purpose.

When a person is poisoned by handling this wood, in a few hours he feels an itching pain, which provokes a scratching, which is followed by an inflammation and swelling. Sometimes a person has had his legs poisoned, which have run with water. Some of the inhabitants of America affirm, they can distinguish this wood by the touch in the dark, from its extreme coldness, which is like ice; but what is mentioned of this poisonous quality, is most applicable to the fourth sort here mentioned, which, by the description, agrees with this species.

The juice of the tree is milky, when it first issues out of the wounded part; but soon after it is exposed to the air, it turns black, and has a very strong foetid scent, and is corroding; for I have observed, on cutting off a small branch from one of these shrubs, that the blade of the knife has been changed black in a moment's time, so far as the juice had spread over it, which I could not get off without grinding the knife.

The eighth sort grows naturally in Jamaica on the red hills, and at Campeachy in great plenty. It has a thick woody stem, which rises near thirty feet high, with a smooth ash-coloured bark, sending out ligneous branches on every side, which have a hairy rusty-coloured bark, garnished with trifoliate leaves, which have hairy foot-stalks. The lobes are spear-shaped, unequally sawed towards the top, and have many transverse veins running from the midrib to the borders, and have a brown woolly down on their under-side. The flowers are ranged in a single racemus, which springs from the wings of the branches; they are small, of a yellowish colour, and the female flowers are succeeded by small oval berries, of an orange colour when ripe.

The ninth sort grows naturally about Carthage in New Spain; this rises with a shrubby stalk twelve or fourteen feet high, covered with a grey bark, sending out a great number of branches on every side, which are garnished with trifoliate smooth leaves, whose lobes are oval, spear-shaped, and oblique to their foot-stalks. The male and female flowers are upon different plants; they are formed in loose panicles, are small, and of a dirty white colour. The female flowers are succeeded by small, oval, smooth berries, each including one seed.

The two last sorts are tender plants, so will not thrive in this country, without the assistance of artificial heat; they are propagated by seeds, when these can be procured from the countries where the plants grow naturally. These should be sown as soon as they arrive here, in pots filled with light earth, and plunged into a tan-bed. Sometimes the plants will come up the same year, but the seeds often lie long in the ground when they are sown in the spring; and when they do not grow the first year, the pots should be plunged in the bark-bed in the stove in autumn, where they may remain all the winter; and in the spring they should be plunged into a fresh hot-bed under a frame, which will soon bring up the plants. When these are fit to remove, they should be each planted in a small pot, filled with light earth, and plunged into a new tan-bed, observing to shade them from the sun till they have taken new root; then they should be treated in the same way as other tender exotic plants, which are constantly kept in the bark-stove. *Miller's Gard. Dict.*

TOXICUM, a sort of poison, said to be used by the Indians to their arrows, in order to render wounds made by them incurable.

TRABEATION, in the ancient architecture, the same with entablature. See the article **ENTABLATURE**.

TRACES of the Brain, among the Cartesians, denotes the impressions which sensible objects make on the fine fibres of the brain, by means of the organs of sense; on which impressions memory, imagination, &c. are supposed, in a great measure to depend. See **MEMORY**, &c.

TRACHEA, in anatomy. See the article **ASPERA ARTERIA**.

TRACHELIUM, in botany, a genus of plants, with a funnel fashioned flower, divided into five segments at the limb; the fruit is a roundish obtusely trilobous capsule, containing a great number of very minute seeds: It is a native of Italy, and grows naturally in shady-woods.

This plant is propagated by seeds, which should be sown in autumn soon after they are ripe; for when they are kept out of the ground till spring, they frequently fail, or if they do grow, it is not before the following spring. When the plants come up, they should be kept clean from weeds, and as soon as they are big enough to remove, should be transplanted on an east aspect border of light undunged earth, placing them in rows six inches apart, and four inches distant in the rows, shading them from the sun till they have taken new root; after which they require no other care but to keep them clean from weeds till autumn, when they may be transplanted into the borders of the flower-garden, where they will flower the following summer.

But as these plants thrive better on old walls, when by accident they have arisen from seeds, so their seeds, when ripe, may be scattered on such walls as are old, or where there is earth lodged sufficient to receive the seeds, where the plants will come up and resist the cold much better, and continue longer than when sown in the full ground; and when a few of the plants are established on the walls, they will shed their seeds, so that they will maintain themselves without any farther care. Mr. Miller says he has observed some plants of this kind, which have grown from the joints of a wall, where there has not been the least earth to support them, which have resisted the cold, tho' they have been greatly exposed to the winds, when most of those in the full ground were killed; so that these plants are very proper to cover the walls of ruins, where they will have a very good effect.

TRACHEOTOMY, in surgery, the name of an operation otherwise called bronchotomy. See the article **BRONCHOTOMY**.

TRACING, in husbandry, a term used by our planters in the method of preserving the maize or Indian corn. This, being a large grain, is apt to spoil, if not carefully preserved.

Some thresh out the corn as soon as the ears are gathered, and lay it up in holes of the earth, which are their granaries: but those who have not opportunities of doing this, trace it, that is, they leave it in the ear, and weave or fasten together a great number of ears by the ends of the husks: these traces of corn they hang up within doors, on such supports as will keep them from one another; and they will, in this manner, keep good the whole winter.

This is a method of our introducing; but their own of burying the clean corn was at least as good, and was the same practised by the Egyptians of old, and by all the wisest nations of the East at this time. But whether we have improved their husbandry in this particular, or not, it is certain that we have greatly assisted them in the planting this corn, which we do by the plough, instead of the troublesome method they had of doing it with the hoe. The manner of our planting it is this; we plough single furrows the whole length of the field, and at about six feet distance one from another; we then plough others across at the same distance, and then, wherever the furrows meet, the corn is thrown in; it is then covered either by the hoe, or by turning another furrow behind it with the plough; and when the weeds begin to overtop the corn, they plough the spaces again, and by this means destroy and turn in all the weeds, and give the earth stirring that greatly assists vegetation.

TRACT, in geography, an extent of ground, or a portion of the earth's surface.

TRACT, in matters of literature, denotes a small treatise, or written discourse, upon any subject.

TRACTION, the art of drawing, whereby a thing is brought nearer to the mover.

TRACTRIX, in geometry, a curve otherwise called catenaria.

TRADE, in general, denotes the same with commerce, consisting in buying, selling, and exchanging of commodities, bills, money, &c.

The first notions of trade arose from the light of nature. One family no sooner found that they could not live without the assistance of another, but they established a trade by way of barter. As the nations increased, markets were every where established for the same purpose, where a sheep was exchanged for a sack of corn, or an ox for some other necessities of life. This introduced the use of weights and measures; but trade never became an art, till the invention of spinning and weaving, whose manufactures introduced a variety of dealing.

Trade, in the next place, regulated the value of all kinds of commodities by a common measure or standard, from the inconveniencies of barter, and a certain equivalent, called money, was agreed upon for all sorts of goods. Formerly, in England, leather money was used; and the Africans still use cowries, or white speckled shells, called black-a-moor's teeth. But, in process of time, silver and gold being found most convenient to make money of, they are become the common standard of all commodities; which are purchased with more or less money, in proportion to the plenty and scarcity of the goods brought to market; from hence we date the terms of dearth or cheapness.

At the introduction of metal money, the merchant adjusted its value only by weight; but this being found inconvenient, its weight or value was ascertained by a stamp or mark, which is what we call coin. Money not only serves commodiously to settle the price of all goods, but it serves to pay for labour, to purchase houses, lands, &c. so that from hence arises the notion of riches.

This has been the great foundation of commerce; because, as many nations want this depository of wealth, which seems to be confined to certain countries; and as these

these nations, without it, must have remained poor, had they not some method of acquiring this treasure; it has caused an intercourse between those nations; so that what was called trade, so long as confined between people of the same country, is properly stiled commerce, when it is carried into so large an extent.

Commerce could not be established without shipping. At least, those nations who have applied themselves to that adventurous commerce, have in all ages exceeded those in riches, power, and necessities of life, who enjoyed a better climate, soil, or situation.

Nothing could be so great a spur to industry, as the invention of trade. When a man knows that his labour shall be crowned with plenty, he proceeds with courage, vigour, and activity; he is daily either inventing new schemes, or carrying arts, already known, to the utmost perfection. In which view, trade is the great principle of science, both theoretical and practical.

Again, it is to trade that we ascribe the beginning of civility and society: and when this had improved men's circumstances, the desire of keeping, and quietly enjoying the property so obtained, introduced and established equal, limited, and legal governments; and living under, and the being protected by such governments, is properly stiled liberty; which, therefore, is not only highly consistent with, but, in some measure, essentially necessary to trade.

But what has at all times recommended commerce beyond all other acquisitions, is the power, or ability of independency, which it gives to that nation where it flourishes most. There is no maxim more incontestable in all ages, than that the people who prevail at sea, will in the end, prevail on shore. No maritime power was ever ruined by a land war, till her power was first broken at sea, or she lost the power of the sea.

Therefore, if liberty, property, and equal government, a flourishing state of learning, perfection in arts and sciences, public magnificence, private abundance, and a capacity of defending and preserving these blessings against all invaders, be certain and incontestable benefits, they are such as commerce, and such as commerce alone, is able to give to any people or nation.

TRADE-WINDS denote certain regular winds at sea, blowing either constantly the same way, or alternately this way and that; thus called from their great use in navigation, and the Indian commerce.

The trade winds are of different kinds, some blowing three or six months of the year one way, and then the like space of time the opposite way; very common in the Indian seas, and called monsoons.

Others blow constantly the same way; such is that general wind between the tropics, which, off at sea, is found to blow all day long from east to west.—For the phenomena of each, with their physical causes, see the article WIND.

TRADESCANTIA, in botany, a genus of plants, the flower of which consists of three orbiculated, plane, and very patent petals; and its fruit is an oval trilocular capsule, containing a few angular seeds.

This plant is easily propagated by seeds, which, if they are permitted to scatter, will produce plenty of young plants the following spring; or if the seeds are sown soon after they are ripe, the plants will come up the spring after; and when they are fit to remove, they should be planted in a nursery-bed at about nine inches distance, and the ground kept clean from weeds. In autumn they should be removed into the borders of the flower-garden, where they will flower and produce seeds, and the roots will continue several years.

TRADITION, among ecclesiastical writers, denotes certain regulations regarding the rites, ceremonies, &c. of religion, which we suppose to have been handed down from the days of the apostles, to the present time.

Tradition is distinguished into written, of which there are some traces in the writings of the ancient fathers; and unwritten, of which no mention is made in the writers of the first ages of Christianity.

TRAGACANTH, *Tragacantha*, in botany, a genus of plants; the empalement of the flower is indented in five parts, the lower segments being the shortest. The

flower is of the butterfly kind; the standard is long, erect, indented at the point; the borders are reflexed. The wings are shorter than the standard. The keel is of the same length with the wings, and is indented; it has ten stamina, nine are joined and one is separated, terminated by roundish summits, and a sharp taper germen, supporting an oval-shaped style, crowned by an obtuse stigma. The germen afterward becomes a short swelling pod, having two longitudinal rolls, inclosing kidney-shaped seeds.

There are four species of this plant enumerated by Mr. Miller: the first grow naturally on the sea-shore about Marseilles, and in Italy; this has a thick, short, ligneous stalk, which branches out greatly on every side. The young branches are woolly, closely garnished with winged leaves, whose foot-stalks end in acute thorns. The lobes are small, oval, obtuse, and of a silvery colour. The flowers are large, white, and shaped like a butterfly; they are produced in clusters at the end of the branches, and are succeeded by short pods, having two longitudinal cells, containing two or three kidney-shaped seeds, which seldom ripen in England.

The second sort grows naturally in the islands of Majorca and Minorca; this hath a thick woody stalk, rising about two feet high, sending out many ligneous branches, closely garnished with small, spear-shaped, hoary leaves, ranged by pairs along a very strong foot-stalk, ending with a sharp thorn. The flowers are produced singly from the sides of the branches; they are large, white, and are succeeded by oval bladder pods, containing four kidney-shaped seeds, which do not ripen in England.

The third sort grows naturally in the islands of the Archipelago; this has a very low shrubby stalk, divided into many downy branches, garnished with winged leaves, composed of nine or ten pair of spear-shaped woolly lobes, ending in acute thorns. The flowers are produced from the side and at the top of the branches; they are white, and shaped like those of the other species, but smaller.

The fourth sort grows naturally in Spain; this is a very low plant. The stalks are pretty thick and woody, but seldom rise more than five or six inches high, dividing into several bunches, closely garnished with small winged leaves, composed of several pair of small, linear, smooth lobes, of a bright green colour. The foot-stalks of these end in very sharp thorns, which stand out beyond the lobes; the flowers grow in clusters from the side of the stalks: they are smaller than those of the other species, and of a dirty white colour.

These sorts may be propagated by seeds, when they can be procured from the countries where the plants grow naturally, which should be sown on a bed of fresh earth in April; and when the plants come up, they should be carefully kept clean from weeds. If the season should prove very dry, it would be of great service to water the plants now and then; when they are large enough to transplant, they should be carefully taken up, and some of them planted in small pots, filled with fresh earth, placing them in the shade until they have taken new root; then they may be removed into an open situation, where they may remain till the latter end of October, when they should be placed under a common frame, where they may be sheltered from severe frost, but may have free air in mild weather.

The remainder of the plants may be planted on a warm dry bank, where they must be shaded until they take root; and if the season should continue dry, they must be refreshed with water, otherwise they will be in danger, because, while they are so young, their roots will not have established themselves in the ground sufficiently to nourish them in great droughts.

Those plants which were planted in pots, may be preserved under frames in winter, until they have obtained strength, when they may be shaken out of the pots, and planted in a lean dry soil and a warm situation, where they will endure the cold of our ordinary winters very well; but, as they are sometimes destroyed by hard frosts, it will be proper to keep a plant of each kind in pots, which may be sheltered in winter, to preserve the species.

These plants may also be propagated by slips, for as they rarely produce seeds in this country, the latter method is generally used here. The best time for this work is in April, just as the plants begin to shoot, at which time the tender branches of the plants should be slipped off, and their lower parts divested of the decayed leaves; then they should be planted on a very moderate hot-bed, which should be covered with mats, to screen them from the great heat of the sun by day and the cold by night. These cuttings should be greatly watered until they have taken root; then they may be exposed to the open air, observing always to keep them clear from weeds.

On this bed they may remain until the following spring, where, if the winter should be very severe, they may be covered with mats as before; and in April they may be transplanted out either into pots, filled with sandy light earth, or into warm borders, where, if the soil be dry, gravelly, and poor, they will endure the severest cold of our climate; but if they are planted in a very rich soil, they often decay in winter.

Gum-tragacanth, or, as some call it, gum-adragant, or gum-dragon, is the produce of one of the species of this genus. The gum is brought to us in long and slender pieces, of a flattened figure, more or less, and these not straight, or rarely so; but commonly twisted and contorted various ways, so as to resemble worms. We sometimes meet with it like the other vegetable exudations, in roundish drops, but these are much more rare. It is moderately heavy, of a firm consistence, and, properly speaking, very tough rather than hard, and is extremely difficult to powder, unless first carefully dried, and the mortar and pestle kept warm. Its natural colour is a pale whitish, and in the cleanest pieces it is something transparent. It is often, however, met with tinged brownish, and of other colours, and more opaque. It has no smell, and very little taste, but what it has is disagreeable. Taken into the mouth, it does not grow clammy, and stick to the teeth, as the gum-arabic does, but melts into a kind of very soft mucilage. It dissolves in water but slowly, and communicates its mucilaginous quality to a great quantity of that fluid. It is by no means soluble in oily or spirituous liquors, nor is it inflammable. It is brought to us from the island of Crete, and from several parts of Asia. It is to be chosen in long twisted pieces, of a whitish colour, very clear, and free from all other colours; the brown, and particularly the black, are wholly to be rejected.

Tragacanth has the same virtues with gum-arabic, but in a greater degree. It greatly inspissates and obtunds the acrimony of the humours, and is therefore found of vast service in inveterate coughs, and other disorders of the breast, arising from an acrid phlegm, and in stranguries, heat of urine, and all other complaints of that kind. It is usually given in the compound powder, called the species diatragacanthi frigidæ, rarely alone. It is also, by some, esteemed a very great external remedy for wounds, and in this sense made an ingredient in some sympathetic powders, with vitriol and other things. It is by some recommended alone, in form of a powder or strong mucilage, for cracks and chaps in the nipples of women: but it is found, by experience, to be a very troublesome application in those cases, and to do more harm than good, as it dries by the heat of the part, and draws the lips of the wound farther asunder than before.

TRAGEA, in pharmacy, an aromatic powder, grossly beaten and mixed with sugar, taken by way of carminative.

TRAGEDY, a dramatic poem, representing some signal action performed by illustrious persons, and which has frequently a fatal issue, or end.

Aristotle, more scientifically, defines tragedy, the imitation of one grave and entire action, of a just length, and which without the assistance of narration, by raising of terror and compassion, refines and purges our passions. This definition has given the critics some perplexity; and Corneille declares he cannot reconcile Aristotle with himself: the instances Aristotle cites, he thinks, ruin his own definition; he even denies the purging our passions to be the end of tragedy. Our English authors are more favourable to the definition; by the purging

our passions, they understand not the extirpating them, but the reducing them to just bounds; for by shewing the miseries that attend a subjection to them, it teaches us to watch them more narrowly; and by seeing the great misfortunes of others, it lessens the sense of our own.

Tragedy, in its original, M. Hedelin observes, was only a hymn sung in honour of Bacchus, by several persons, who, together, made a chorus of music, with dances and instruments. As this was long, and might fatigue the fingers, as well as tire the audience, they be-thought themselves to divide the singing of the chorus into several parts, and to have certain recitations in the intervals. Accordingly Thespis first introduced a person upon the stage with this view. Æschylus, finding one person insufficient, introduced a second, to entertain the audience more agreeably, by a kind of dialogue: he also clothed his persons more decently, and first put on them the buskin.

The persons who made these recitations on the scene, were called actors; so that tragedy was at first without actors. And what they thus rehearsed, being things added to the singing of the chorus, of which they were no necessary part, were called episodes.

Sophocles found that two persons were not enough for the variety of incidents, and accordingly introduced a third: and here the Greeks seem to have stopped; at least, it is very rare that they introduced four speakers in the same scene.

Tragedy and comedy were, at first, confounded with each other, but were afterwards separated; and the poets applied themselves to the cultivating of tragedy, neglecting comedy.

When tragedy was got into a better form, they changed the measure of its verse, and endeavoured to bring the action within the compass of a day, or of a revolution of the sun.

The English received the first plan of their drama from the French, among whom it had its rise towards the end of Charles V. under the title of Chant-royal, which consisted of pieces in verse, composed in honour of the Virgin, or some of the saints, and sung on the stage: they were called by the title of chant-royal, because the subject was given by the king of the year, or the person who had borne away the prize the year preceding.

The humour of these pieces ran wonderfully among the people, insomuch that in a little time there were formed several societies, who began to vie with each other: one of these, to engage the town from the rest, began to intermix various incidents or episodes, which they distributed into acts, scenes, and as many different persons as were necessary for the representation. Their first essay was in the Bourg St. Mawes, and their subject the passion of our Saviour. The provost of Paris prohibiting their continuing it, they made application to court; and to render it the more favourable to them, elected themselves into a friary or fraternity, under the title of Brothers of the Passion: which title has given some occasion to suspect them to have been an order of religious.

The king, on seeing and approving some of their pieces, granted them letters of establishment, in 1402; upon which they built a theatre, and for an age and a half acted none but grave pieces, which they called moralities; till, the people growing weary of them, they began to intermix farces, or interludes, from prophane subjects.

This mixture of farce and religion displeasing many, they were re-established by an arret of parliament, in 1548, on condition of their acting none but proper, lawful, and decent subjects, without intermeddling with any of the mysteries of religion; and thus were the Brothers of the Passion despoiled of their religious character: upon which they mounted the stage no more in person, but brought up a new set of comedians, who acted under their direction.

Thus was the drama established, and on this foundation arrived in England. In process of time, as it was improved, it became divided into two branches, agreeable to the practice of the ancients, and the nature of things,

things, viz. into tragedy and comedy, properly so called; and this last again was sub-divided into pure comedy and farce.

TRAGI-COMEDY, a dramatic piece partaking of the nature both of tragedy and comedy, the event of which is not bloody or unhappy, and wherein is admitted a mixture of less serious characters.

The foundation of tragi-comedy is certainly bad; for endeavouring to make us laugh and cry by turns, it endeavours at contrary motions, which the heart can never undergo; every thing that disposes for the one, indisposing for the other: for which reason it is at present, with great justice, disused. However, tragi-comedy is allowed to introduce kings and heroes.

TRAGOPOGON, Goats Beard, in botany, a genus of plants; the common empalement of the flower is single, composed of eight acute pointed leaves, which are alternately large, joined at their base. The flower is composed of many hermaphrodite florets, which are uniform, of one petal, stretched out like a tongue, indented at their points in five parts, and lie over each other like the scales of fish; these have each five short hair-like stamina, terminated by cylindrical summits, and an oblong germen, situated under the floret, supporting a slender style the length of the stamina, crowned by two revolving stigmas. The empalement of the flower afterwards swells to a belly, inclosing many oblong, angular, rough seeds, slender at both ends, crowned by a feathery down.

There are six species of this plant, the first growing naturally in the meadows of Austria and Germany; this is very different from the second, which grows naturally in England; for the seeds of both have been sown several years in the same bed of earth, and have always been found to retain a difference. The lower leaves of this are three quarters of an inch broad at their base, where they embrace the stalk, and more than a foot long, closed together, ending in acute points. The stalk rises near three feet high, garnished at each joint with one leaf, of the same shape with those below, but smaller: it is terminated by one large yellow flower, composed of hermaphrodite florets, which lie over each other like the scales of fish; these are included in one common simple empalement, which is equal in length to the rays of the flower. Each floret is succeeded by an oblong seed, which is larger at the base than at the point, where it is crowned with a large feathery down. The seeds of the border or ray are crooked and rough, but those of the disk are strait and smooth.

The second sort grows naturally in moist pastures in many parts of England; it is by the common people titled sleep-at-noon, or go-to-bed-at-noon, because the flowers are generally closed up before that time every day. The lower leaves of this sort are almost as long as those of the first sort, but are not more than a third part so broad; they are of a deep green colour, and end in acute points. The stalks rise about a foot high, and sustain one yellow flower at the top, not more than half so large as those of the first; the empalements of these flowers are longer than the rays, and the seeds are much smaller than those of the other.

When this sort shoots up in stalks four inches high, the common people gather it out of the fields, and boil it in the same way as asparagus, and some give it the preference.

The third sort is cultivated in gardens by the title of falfafy. The roots of this are dressed in different ways, and served up to the table; but of late years some persons cultivate it for the stalks, which are cut in the spring, when they are four or five inches high, which are dressed like asparagus, in the like manner as the second sort. The stalks of this are much longer, and are tenderer than the other, so are better for the purpose than those of the second sort; the leaves are broad; the flowers are large and blue; the foot-stalk immediately under the flower is much thicker than below, and the empalement is longer than the rays of the flower.

The fourth sort grows naturally in Italy; this is of low stature. The stalks seldom rise a foot high; the leaves are long and narrow; the flowers are small, and of a pale red or peach-blossom colour; the empalement

is much longer than the rays of the flower, and the seeds are smooth.

The fifth sort grows naturally in Istria; this has narrow hairy leaves. The stalks rise about a foot and a half high, are naked most part of their length, very hairy, and sustain one pretty large yellow flower, whose empalement is much shorter than the rays of the flower, which is also very hairy.

The sixth sort grows naturally in Crete, and also in Italy; this is an annual plant, very like the fowthistle in stalk and leaf, but the empalement of the flower is prickly. It is seldom admitted into gardens, because the seeds are wafted by the winds to a great distance, and thereby fill the garden with the plants.

These plants are propagated from seeds, which should be sown in April upon an open spot of ground, in rows about nine or ten inches distance; and when the plants are come up, they should be hoed out, leaving them about six inches asunder in the rows. The weeds should also be carefully hoed down as they are produced, otherwise they will soon overbear the plants, and spoil them. This is all the culture required, and if the soil be light and not too dry, the plants will have large roots before winter; at which time the falfafy, whose roots are eaten at that season, will be fit for use, and may be taken up at any time after their leaves begin to decay; but, when they begin to shoot again, they will be sticky, and not fit for use; but many persons cultivate this sort for the shoots, as was before mentioned.

The common yellow sort, whose shoots are sold in the market, will be fit for use in April or May, according to the forwardness of the season. The best time to cut them is, when their stems are about four inches long, for if they stand too long, they are never so tender as those which are cut while young.

Some people, in cultivating these plants, sow their seeds in beds pretty close; and when they come up, they transplant them out in rows at the before mentioned distance; but, as they form tap-roots, which abound with a milky juice, when the extreme part of their roots is broken by transplanting, they seldom thrive well afterward; therefore, it is by far the better way to make shallow drills in the ground, and scatter the seeds therein, as before directed, whereby the rows will be at a due distance, and there will be nothing more to do than to hoe out the plants when they are too thick in the rows, which will be much less trouble than the other method of transplanting, and the plants will be much larger and fairer.

TRAGUS, τραγός, in anatomy, one of the protuberances of the auricle, or external ear, called also hircus, because usually hairy. The tragus is that protuberance next the temple: that on the opposite side, to which the soft lobe of the ear is annexed, is called the antitragus. See the article EAR.

TRAJAN COLUMN, a famous historical column erected in Rome, in honour of the emperor Trajan. It is of the Tuscan order, though something irregular; its height is eight diameters, and its pedestal Corinthian: it was built in a large square there, called Forum Romanum. Its base consists of twelve stones, of an enormous size, and it is raised on a socle, or foot of eight steps; within side is a stair-case, illuminated with forty-four windows. It is 140 feet high, which is thirty-five short of the Antonine column, but the workmanship of the former is much more valued. It is adorned from top to bottom with basso relievo's representing the great actions of that emperor against the Dacæ.

TRAJECTORY of a Comet, is its path or orbit, or the line it describes in its motion. See the article COMET.

TRAIL-BOARD, in a ship, a carved board on each side of her beak, which reaches from the main stem to the figure, or the brackets.

TRAIN, the attendance of a great person, or the trail of a gown, or robe of state. In falconry, it denotes the tail of an hawk.

TRAIN, is likewise used for the number of beats which a watch makes in an hour, or any other certain time.

TRAIN,

TRAIN, is also used for a line of gun-powder, laid to give fire to a quantity thereof, in order to do execution by blowing up earth, works, buildings, &c.

TRAIN, or **TRAILE OF ARTILLERY**, includes the great guns, and other pieces of ordnance belonging to an army in the field. See the article **CANNON**.

TRAIN-OIL, the oil procured from the blubber of a whale by boiling.

TRAIN-BANDS, or **TRAINED-BANDS**, a name given to the militia of England.

TRAINING, or **TRACING**, in mineralogy, a term used by the miners to express the tracing up the mineral appearances on the surface of the earth to their head, or original place, and there finding a mine of the metal they contain.

TRAITOR, or **TRAYTOR**, a person guilty of treason.

TRAMBLING of *Tin Ore*, among miners, the washing it very clean, which is done in a shovel, and in a frame of boards. See the article **TIN**.

TRAMEL, an instrument, or device, sometimes of leather, more usually of rope, fitted to a horse's legs, to regulate his motions, and form him to an amble. It is also taken in many places for an iron moveable instrument in chimnies to hang pots over the fire.

TRAMEL-NET, is a long net wherewith to take fowl by night in champain countries, much like the net used for the low bell, both in shape, bigness, and meshes. To use it, they spread it on the ground, so as the nether or farther end fitted with small plumbets, may lie loose thereon; then the other part being borne up by men placed at the fore ends, it is thus trailed along the ground. At each side are carried great blazing lights, by which the birds are raised, and as they rise under the net they are taken.

TRAMONTANE, or **TRAMONTAIN**, something beyond, or on the farther side the mountains, applied particularly by the Italians, to such as live on the other side the Alps, i. e. all out of Italy, as the Germans, Flemish, French, &c.

TRANGLE, in heraldry, the diminutive of a fess, commonly called a bar.

TRANSACTION, *Transactio*, in the civil law, an accommodation of some business, or dispute between two parties, by a mutual and voluntary agreement between them. See **ACCOMMODATION**.

Philosophical TRANSACTIONS, a kind of journal of the principal things that come before the Royal Society of London. See the article **SOCIETY**.

It appears, that the printing of these transactions was always, from time to time, the single act of the respective secretaries of the society, till the publication of the 47th volume, in 1753, notwithstanding it has been the common opinion, that they were published by the authority and under the direction of the society itself. The truth is, that the society, as a body, never did interest themselves further in their publication, than by occasionally recommending the revival of them to some of their secretaries, when, from the particular circumstances of their affairs, the transactions had happened for any length of time to be intermitted, and this seems principally to have been done with a view to satisfy the public, that their usual meetings were then continued for the improvement of knowledge and benefit of mankind, the great ends of their first institution; but the society being of late years greatly enlarged, and their communications more numerous, they thought it advisable, that a committee of their members should be appointed to re-consider the papers read before them, and select out of them such as they should judge proper for publication in the future transactions, which was accordingly done upon the 26th of March, 1752.

TRANSCENDANT, or **TRANSCENDENTAL**, something raised or elevated beyond other things; or which passes and transcends the nature and circumstances of other inferior beings, so as not to be intimately and essentially included under them.

TRANSCENDENTAL QUANTITIES, among geometers, are indeterminate ones; or such as cannot be expressed, or fixed to any constant equation.—Such is the transcendental curve, or the like.

M. Leibnitz has a dissertation in the *Acta Erudit. Lips.* wherein some problems are neither plain, solid, nor sursolid; nor of any certain degree, but transcend all algebraical equations. He also shews how it may be demonstrated without calculus that an algebraic quadratrix for the circle or hyperbola is impossible: for, if such quadratrix could be found, it would follow that by means thereof any angle, ratio, or logarithm, might be divided in a given proportion of one right-line to another, and this by an universal construction, and, consequently, the problem of the section of an angle, or the invention of any number of mean proportionals, would be a certain finite degree: whereas the different degrees of algebraical equations, and, therefore, the problem understood in general of any number of parts of an angle, or mean proportionals, is of an indefinite degree, and transcends all algebraical equations.

TRANSCENDENTAL Curve, in the higher geometry, is such a one as cannot be defined by any algebraic equation; or which, when expressed by an equation, one of the terms thereof is a variable quantity.

These curves are the same with what Des Cartes, and, after his example, several others call mechanical curves, and which they would have excluded out of geometry; but Sir Isaac Newton and M. Leibnitz are of another sentiment, for, in effect, in the construction of geometrical problems, one curve is not to be preferred to another, as it is defined by a more simple equation, but as it is more easily described than that other. And some of these transcendental, or mechanical, curves are found of greater use than all the algebraical ones together, except the circle.

Add, that M. Leibnitz, in the *Acta Erudit. Lips.* gives us a kind of transcendental equations, whereby these transcendental curves are actually defined, and which are of an indefinite degree; that is, are not always the same in all the points of the curve.

Whereas algebraists use to assume some general letters or numbers for the quantities sought, in these transcendental problems, M. Leibnitz assumes general or indefinite equations for the lines sought; e. gr. putting x and y for the abscissa and ordinate, the equation he uses for a line sought is $a + bx + cy + exy + fxx + gyy$, &c. $= 0$. By the help of which, indefinite equation, in reality, is finite; for it always may be determined, how far soever it is necessary to raise it, he seeks the tangent; and that which results comparing with the given property of tangents, he finds the value of assumed letters a, b, c , &c. and thus defines the equation of the line sought.

If the comparison, abovementioned, do not proceed, he pronounces the line sought, not to be an algebraical, but a transcendental one.

This supposed, he goes on to find the species of transcendency: for some transcendentals depend on the general division or section of a ratio, or upon the logarithms; others upon the arcs of a circle, and others on more indefinite and compound inquiries.

He therefore, besides the symbols x and y , assumes a third, as v , which denotes the transcendental quantity; and of these three forms a general equation for the line sought, from which he finds the tangent, according to the differential method; which succeeds even in transcendental quantities. What he finds he compares with the given properties of the tangent, and so discovers, not only the values of a, b, c , &c. but also, the particular nature of the transcendental quantity.

And though it may sometimes happen, that the several transcendentals are so to be made use of, and those of different natures too, one from another; also, though there be transcendentals or transcendentals, and a progression of these in infinitum: yet we may be satisfied with the most easy and useful one, and, for the most part, may have recourse to some peculiar artifices for shortening the calculus, and rendering the problem to as simple a term as may be.

This method being applied to the business of quadratures, or to the invention of quadrics, in which the property of the tangent is always given, it is manifest, not only how it may be discovered, whether the indefinite quadrature may be algebraically impossible, but, also how, when this impossibility is discovered, a transcendental

dental quadratrix may be found; which is a thing which had not before been shewn. So that it seems that geometry, by this method, is carried infinitely beyond the bounds to which Vieta and Des Cartes brought it; since, by this means, a certain and general analysis is established, which extends to all the problems which are of no certain degree, and, consequently, not comprehended within algebraical equations.

Again, in order to manage transcendental problems (wherever the business of tangents or quadratures occurs) by a calculus, there is hardly any that can be imagined shorter, more advantageous, or universal, than the differential calculus, or analysis of indivisibles and infinites.

By this method we may explain the nature of transcendental lines by an equation: e. gr. Let z be the arc of a circle whose radius is r , and x the versed sine: then

will $z = \sqrt{\frac{rx}{2rx+x^2}}$; and, if the ordinate of the cycloid be y , then will $y = \sqrt{2rx+x^2} + z$, or the fluent of $\sqrt{2rx-x^2}$, which equation perfectly expresses the relation between the ordinate y and the abscissa x , and from it all the properties of the cycloid may be demonstrated.

Thus is the analytical calculus extended to those lines, which have hitherto been excluded, for no other cause, but that they were thought incapable of it.

TRANSCOLATION, in pharmacy, the same with filtration, or percolation. See the article **FILTRATION**.

TRANSCRIPT, a copy of any original writing, particularly that of an act, or instrument, inserted in the body of another.

TRANSFER, in commerce, &c. an act whereby a person surrenders his right, interest, or property in any thing moveable or immoveable to another.

The term transfer, is chiefly used for the assigning and making over shares in the stocks, or public funds, to such as purchase them of the proprietors.

TRANSFORMATION, in general, denotes a change of form, or the assuming a new form different from a former one. The chemists have been for a long time seeking the transformation of metals; that is, their transmutation, or the manner of changing them into gold. See **TRANSMUTATION**.

TRANSFORMATION of Equations. The doctrine of the transformation of equations, and of exterminating their intermediate terms, is thus taught by Mr. Mac Laurin. The affirmative roots of an equation are changed into negative roots of the same value, and the negative roots into affirmative, by only changing the signs of the terms alternately, beginning with the second. Thus, the roots of the equation $x^4 - x^3 - 19x^2 + 49x - 30 = 0$, are $+1, +2, +3, +5$; whereas the roots of the same equation having only the signs of the second and fourth terms changed, viz. $x^4 + x^3 - 19x^2 - 49x - 30 = 0$, are $-1, -2, -3, +5$.

To understand the reason of this rule, let us assume an equation, as $x - a \times x - b \times x - c \times x - d \times x - e$, &c. $= 0$, whose roots are $+a, +b, +c, +d, +e$, &c. and another having its roots of the same value, but affected with contrary signs, as $x + a \times x + b \times x + c \times x + d \times x + e$, &c. $= 0$. It is plain, that the terms taken alternately, beginning from the first, are the same in both equations, and have the same sign, being products of an even number of the roots; the product of any two roots having the same sign as their product when both their signs are changed; as $+a \times -b = -a \times +b$.

But the second terms and all taken alternately from them, because their coefficients involve always the products of an odd number of the roots, will have contrary signs in the two equations. For example, the product of four, viz. $abcd$, having the same sign in both, and one equation in the fifth term having $abcd \times +e$, and the other $abcd \times -e$, it follows, that their product $abcde$ must have contrary signs in the two equations: These two equations, therefore, that have the same

roots, but with contrary signs, have nothing different but the signs of the alternate terms, beginning with the second. From which it follows, that if any equation is given, and you change the signs of the alternate terms, beginning with the second, the new equation will have roots of the same value, but with contrary signs.

It is often very useful to transform an equation into another that shall have its roots greater or less than the roots of the proposed equation by some given difference.

Let the equation proposed be the cubic $x^3 - px^2 + qx - r = 0$. And let it be required to transform it into another equation, whose roots shall be less than the roots of this equation by the given difference (e); that is, suppose $y = x - e$, and consequently, $x = y + e$; then, instead of x , and its powers, substitute $y + e$, and its powers, there will arise this new equation:

$$(A) \left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ - py^2 - 2pey - pe^2 \\ + qy + qe \\ - r \end{aligned} \right\} = 0$$

whose roots are less than the roots of the preceding equation by the difference (e).

If it had been required to find an equation whose roots should be greater than those of the proposed equation by the quantity (e), then we must have supposed $y = x + e$, and consequently, $x = y - e$, and then the other equation would have had this form:

$$(B) \left. \begin{aligned} y^3 - 3ey^2 + 3e^2y - e^3 \\ - py^2 + 2pey - pe^2 \\ + qy - qe \\ - r \end{aligned} \right\} = 0$$

If the proposed equation be in this form, $x^3 + px^2 + qx + r = 0$, then, by supposing $x + e = y$, there will arise an equation agreeing, in all respects, with the equation (A), but that the second and fourth terms will have contrary signs.

And by supposing $x - e = y$, there will arise an equation agreeing with (B), in all respects; but that the second and fourth terms will have contrary signs to what they have in (B).

The first of these suppositions gives this equation,

$$(C) \left. \begin{aligned} y^3 - 3ey^2 + 3e^2y - e^3 \\ + py^2 - 2pey + pe^2 \\ + qy - qe \\ + r \end{aligned} \right\} = 0$$

The second supposition gives the equation,

$$(D) \left. \begin{aligned} y^3 + 3ey^2 + 3e^2y + e^3 \\ + py^2 + 2pey + pe^2 \\ + qy + qe \\ + r \end{aligned} \right\} = 0$$

The first use of this transformation of equations is to shew how the second (or other intermediate) term may be taken away out of an equation.

It is plain, that in the equation (A), whose second term is $3e - p \times y^2$, if you suppose $e = \frac{1}{3}p$, and consequently, $3e - p = 0$, then the second term will vanish.

In the equation (C), whose second term is $-3e + p \times y^2$, supposing $e = \frac{1}{3}p$, the second term also vanishes.

Now the equation (A) was deduced from $x^3 - px^2 + qx - r = 0$, by supposing $y = x - e$; and the equation (C) was deduced from $x^3 + px^2 + qx + r = 0$, by supposing $y = x + e$. From which this rule may easily be deduced for exterminating the second term out of any cubic equation.

Rule. Add to the unknown quantity of the given equation the third part of the coefficient of the second term, with its proper sign, viz. $\mp \frac{1}{3}p$, and suppose this aggregate equal to a new unknown quantity (y). From this value of y , find a value of x by transposition, and substitute this value of x , and its powers, in the given equation, and there will arise a new equation that shall want the second term.

Example. Let it be required to exterminate the second term out of this equation, $x^3 - 9x^2 + 26x - 34 = 0$, suppose $x - 3 = y$, or $y + 3 = x$; and substituting according to the rule, you will find

$$\left. \begin{array}{r} y^3 + 9y^2 + 27y + 27 \\ -9y^2 - 54y - 81 \\ \hline +26y + 78 \\ -34 \end{array} \right\} = 0$$

$$y^3 - y - 10 = 0$$

In which there is no term where y is of two dimensions, and an asterisk is placed in the room of the second term, to shew it is wanting.

Let the equation proposed be of any number of dimensions represented by (n) ; and let the coefficient of the second term, with its sign prefixed, be $-p$; then supposing $x - \frac{p}{n} = y$, and, consequently, $x = y + \frac{p}{n}$, and substituting this value for x in the given equation, there will arise a new equation that shall want the second term.

It is plain, that the sum of the roots of the proposed equation, is $+p$; and since we suppose $y = x - \frac{p}{n}$; it follows, that in the new equation each value of y will be less than the respective value of x by $\frac{p}{n}$; and since the number of the roots is n , it follows, that the sum of the values of y will be less than $+p$, the sum of the values of x , by $n \times \frac{p}{n}$, the difference of any two roots; that is, by $+p$: therefore, the sum of the values of y will be $+p - p = 0$.

But the coefficient of the second term of the equation of y is the sum of the values of y , viz. $+p - p$, and, therefore, that coefficient is equal to nothing; and, consequently, in the equation of y , the second term vanishes. It follows then, that the second term may be exterminated out of any given equation by the following

Rule. Divide the coefficient of the second term of the proposed equation by the number of dimensions of the equation; and assuming a new unknown quantity y , add to it the quotient, having its sign changed. Then suppose this aggregate equal to x , the unknown quantity in the proposed equation; and for x , and its powers, substitute the aggregate and its powers, so shall the new equation, that arises, want its second term.

If the proposed equation is a quadratic, as $x^2 - px + q = 0$, then, according to the rule, suppose $y + \frac{1}{2}p = x$, and, substituting this value for x , you will find

$$\left. \begin{array}{r} y^2 + py + \frac{1}{4}p^2 \\ -py - \frac{1}{2}p^2 \\ \hline +q \end{array} \right\} = 0$$

$$y^2 - \frac{1}{4}p^2 + q = 0$$

And from this example, the use of exterminating the second term appears: for, commonly, the solution of the equation, that wants the second term, is more easy. And, if you can find the value of y from this new equation, it is easy to find the value of x by means of the equation $y + \frac{1}{2}p = x$. For example,

Since $y^2 + q - \frac{1}{4}p^2 = 0$, it follows, that $y^2 = \frac{1}{4}p^2 - q$, and $y = \pm \sqrt{\frac{1}{4}p^2 - q}$, so that $x = y + \frac{1}{2}p = \frac{1}{2}p \pm \sqrt{\frac{1}{4}p^2 - q}$.

If the proposed equation is a biquadratic, as $x^4 - px^3 + qx^2 - rx + s = 0$, then by supposing $x - \frac{1}{4}p = y$, or $x = y + \frac{1}{4}p$, an equation shall arise having no second term. And if the proposed is of five dimensions, then you must suppose $x = y \pm \frac{1}{5}p$. And so on.

When the second term in any equation is wanting, it follows, that the equation has both affirmative and negative roots, and that the sum of the affirmative roots is equal to the sum of the negative roots: by which means, the coefficient of the second term, which is the sum of all the roots of both sorts, vanishes, and makes the second term vanish.

In general, the coefficient of the second term is the difference between the sum of the affirmative roots and the sum of the negative roots: and the operations we have given serve only to diminish all the roots, when the sum of the affirmative is greatest, or increase the roots when the sum of the negative is greatest, so as to balance them, and reduce them to an equality.

It is obvious, that, in a quadratic equation that wants a second term, there must be one root affirmative, and one negative; and these must be equal to one another.

In a cubic equation that wants the second term, there must be either two affirmative roots equal, taken together, to a third root that must be negative; or, two negative equal to a third that must be positive.

Let an equation $x^3 - px^2 + qx - r = 0$ be proposed, and let it be now required to exterminate the third term.

By supposing $y = x - e$, the coefficient of the third term in the equation of y is found (see equation A) to be $3e^2 - 2pe + q$. Suppose that coefficient equal to nothing, and by resolving the quadratic equation $3e^2 - 2pe + q = 0$, you will find the value of e , which, substituted for it in the equation $y = x - e$, will shew how to transform the proposed equation into one that shall want the third term.

$$\text{The quadratic } 3e^2 - 2pe + q = 0 \text{ gives } e = \frac{p \pm \sqrt{p^2 - 3q}}{3}$$

So that the proposed cubic will be transformed into an equation wanting the 3d term, by supposing $y = x - \frac{p - \sqrt{p^2 - 3q}}{3}$, or $y = x - \frac{p + \sqrt{p^2 - 3q}}{3}$.

If the proposed equation is of n dimensions, the value of e , by which the third term may be taken away, is had by resolving the quadratic equation $e^2 + \frac{2p}{n}e + \frac{2q}{n \times n - 1} = 0$, supposing $-p$ and $+q$ to be the coefficients of the second and third terms of the proposed equation.

The fourth term of any equation may be taken away by solving a cubic equation, which is the coefficient of the fourth term in the equation when transformed. The fifth term may be taken away by solving a biquadratic; and, after the same manner, the other terms can be exterminated, if there are any.

TRANSFORMATION of Insects. It is well known that flies are not produced in that form, from the eggs of their parent fly, but undergo a change like that of the butterfly, and the like winged insects; the egg hatching into a worm; and this after eating, and performing all the operations of animal life for a certain time, enters into a state of rest, and thence is changed into a fly.

Though the general course of nature is the same in this respect in flies and butterflies, yet the means and manner of it are different: the butterfly makes its coat for this transformation; the fly-worms of many kinds have only a shell of their own proper skin to undergo this change in.

All the fly-worms of the first and second, and many of those of the third class, have their case thus made only of their own skin; the different species afford indeed some varieties in the manner of this, but a general idea of the work may be had from observing the worm or maggot of the common flesh-fly in its several stages.

When this creature has arrived at its full growth, it finds it not convenient any longer to remain among the food it has till then lived upon; it quits it, and now goes in search of a place where it may wait for its metamorphosis. To this purpose it creeps into the earth, where it remains two or three days without any change; at the end of this time, instead of its pointed figure, its white colour, and soft fleshy substance, it acquires the figure of an egg, and becomes of a chestnut colour, or somewhat reddish, and looks opaque and crustaceous: it is in this state perfectly stiff, and destitute of motion, and the creature seems not only to have lost its form, but wholly to have lost its life also.

This however is not the case; all that is done, is that the creature has absolutely quitted its skin, which is now become hard and of a determinate figure, and is within it completing all its changes. *Reaumur's History of Insects.*

TRANSFUSION, Transfusio, the act of pouring a liquor out of one vessel into another.

TRANSFUSION of the Blood, in surgery, the conveying the arterial blood of one man or animal into the veins of another.

Notwithstanding injections and transfusions are seldom practised by our modern surgeons, they were highly celebrated,

celebrated, and often performed in the last century. The generality of physicians, not without reason, attribute most disorders of the body to some vice in the blood, and therefore, some were led to think, that no method could be more ready to remove and correct that vice, than injecting a proper medicine in the veins, to mix with the blood itself, or the transfusing the sound blood of one animal into the veins of another, instead of that which is diseased. But notwithstanding the vast expectations which had been formed by physicians from this operation, frequently the event turned out worse than the disease; for we are told, that almost all the patients who have been treated this way, degenerated into a stupidity, foolishness, or a raving, or melancholy madness, or have been taken off with a sudden death, either in, or not long after, the operations.

For the transfusion of blood into the veins, first, a vein is to be opened in the patient's arm, or hand, and then a small tube of silver, brass, or ivory, thrust upward into it: the same is to be done with the sound person, only the tube must here be inserted downward, towards the small end of the vein; this done, the smallest of the tubes is to be inserted into the other larger one, by which means, as much blood will pass from the sound person into the patient, as may be thought proper, and then the incised veins are to be dressed, or bound up, as in bleeding: if the patient does not recover after one transfusion, the operation should be repeated again, at convenient intervals; but before the patient receives the blood of the sound person, he ought to be bled proportionably, that the new blood last received, may have the freer circulation. Sometimes a vein is opened in each arm of the patient at the same time, that as much of the vitiated blood may flow out of the orifice as he receives of the sound by the other. If the blood is to be transfused out of some animal into the patient, then a calf or a lamb, for example, is to be secured by ligatures, and one of their veins or arteries opened in the neck, leg, or thigh, and the rest of the operation managed as before.

TRANSGRESSION, *Transgressio*, an offence against some law, or a breach or violation thereof.

TRANSIT, *Transitus*, in astronomy, signifies the passage of any planet just by, or over a fixed star, or the sun, and of the moon in particular, covering or moving over any planet.

TRANSITION, in music, is when a greater note is broken into a less, to soften the roughness of a leap by a gradual passage to the next note following; whence it is commonly called the breaking of a note.

TRANSITION, in rhetoric, is of two sorts. The first is when a speech is introduced abruptly, without express notice given of it; as when Milton gives an account of our first ancestors evening devotions.

Both turned, and under open sky ador'd

The God that made both air, sky, earth and heaven. —

Thou also mad'st the night,

Maker Omnipotent, and thou the day!

The second sort of transition is, when a writer suddenly leaves the subject he is upon, and passes unto another, from which it seems different at first view, but has a relation and connection with it, and serves to illustrate and enlarge it.

TRANSITIVE, in grammar, an epithet applied to such verbs as signify an action which passes from the subject that does it, to or upon another subject which receives it. Under the head of verbs transitive, come what we usually call verbs active and passive; other verbs, whose action does not pass out of themselves, are called neuters, and by some grammarians, intransitives.

TRANSLATION, the act of transferring or removing a thing from one place to another; we say the translation of a bishop's see, a council, a seat of justice, &c.

TRANSLATION is also used for the version of a book, a writing out of one language into another.

TRANSMARINE, something that comes from, or belongs to the parts beyond sea.

TRANSMIGRATION, the removal or transla-

tion of a whole people into another country, by the power of a conqueror.

TRANSMIGRATION, is particularly used for the passage of a soul out of one body into another, being the same with what we otherwise call metempsychosis.

TRANSMISSION, in optics, &c. the act of a transparent body passing the rays of light through its substance, or suffering them to pass; in which sense the word stands opposed to reflection. Transmission is also frequently used in the same sense with reflection, by which most bodies, in transmitting the rays, do also refract them.

The rays of light, Sir Isaac Newton observes, are subject to fits of easy transmission and reflection.

TRANSMUTATION, the act of transforming, or changing one nature into another. Nature, Sir Isaac Newton observes, seems delighted with transmutations: he goes on to enumerate several kinds of natural transmutations; gross bodies, and light, he suspects, may be mutually transmuted into each other; and adds, that all bodies receive their active force from the particles of light, which enter their composition. For all fixed bodies, when well heated, emit light as long as they continue so; and again, light intermingles itself, and inheres in bodies, as often as its rays fall on the solid particles of those bodies. Again, water, which is a fluid, volatile, tasteless salt, is by heat, transmuted into a vapour, which is a kind of air, and by cold, into ice, which is a cold transparent brittle stone, easily dissolvable, and this stone is convertible again into water by heat, as vapour is by cold.

Earth, by heat, becomes fire; and by cold, is converted into earth again; dense bodies, by fermentation, are rarified into various kinds of air; and that air, by fermentation also, and sometimes without, reverts into gross bodies. Quicksilver sometimes puts on the form of a fluid metal, sometimes it appears in shape of a pelucid fragile salt, called sublimate; sometimes of a pelucid volatile white tasteless earth, called mercurius dulcis; by distillation it becomes vapour, and by agitation in vacuo, it shines like fire, &c.

All bodies, beasts, fishes, insects, plants, &c. with all their various parts, grow and increase out of water, and aqueous and saline tinctures; and by putrefaction, all of them revert into water or an aqueous liquor again. Farther, water exposed a while to the open air, puts on a tincture, which, in process of time, has a sediment and a spirit, and before putrefaction, yields nourishment both for animals and vegetables.

TRANSMUTATION, in alchemy, denotes the art of changing or exalting imperfect metals into gold or silver. This is also called the grand operation, and, they say, is to be effected with the philosopher's stone.

Some alchemists hold, that the transmutation should rather be called the perfection of imperfect metals; as holding all metals intended by nature, to arrive equally at the perfection of gold, inasmuch as they are composed of the same matter; and that it is only the impurity of their matrices, that is, of the place wherein they are formed by nature, that has prevented their arriving thereat. The elixir being projected on any of these metals, it is supposed to purge and separate the impure parts from the pure, and to join itself wholly to the mercury, which is the purest part, as being of the same nature.

Whether or no metals may be transmuted into one another, is a point strongly disputed among philosophers; the alchemists strenuously asserting the affirmative. Some metals it is commonly supposed, may be changed into others, e. gr. iron into copper, and lead into tin; but Cardan, and some others, deny even this, and argue farther, that though iron and brass, as being nearly alike in weight and tenacity, &c. provided their colour and hardness could be changed, might be converted into one another, either really or at least apparently; yet would the transmuting or ripening of other metals into gold or silver, be still not less impossible; both as these metals are all to be first calcined, after which they can never again be brought back to their pristine purity, and as there is a generation required which is not the work of art but of nature. Cardan, Lemery, Dickenson, and others, give us accounts of the various impostures of adept

adepti in the business of transmutation; some, for instance, fixing mercury with verdigrease, and then heightening the colour with cadmia, &c. but this, if tried with the coppel, all goes off in fumes; and, in effect, nothing produced this way ought to be adjudged true gold, unless it endure coppelling and cementation, purification with antimony, and the depart. Add, that it must have the malleability, extreme ductility, and specific gravity of gold.

TRANSMUTATION, in geometry, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parallelopiped, &c. In the higher geometry, transmutation is used for the converting a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit of the same tangents, &c. If a rectilinear figure be transmuted into another, it is sufficient that the intersections of the lines which compose it be transferred, and the lines drawn through the same in the new figure. If the figure to be transmuted be curvilinear, the points, tangents, and other right lines by means of which the curve line is to be defined, must be transferred.

TRANSOM, among builders, denotes the piece that is framed across a double light window.

TRANSOM, among mathematicians, signifies the vane of a cross-staff, or a wooden number fixed across, with a square whereon it slides, &c.

TRANSOM, in a ship, a piece of timber, which lies athwart the stern, between the two fashion-pieces, directly under the gun-room-port.

TRANSPARENCY, in physics, a quality in certain bodies, whereby they give passage to the rays of light.

The transparency of natural bodies, as glass, water, air, &c. some have imputed to the great number and size of the pores or interstices between the particles of these bodies: but this account is exceedingly defective; for the most solid and opaque body in nature, we know, contains a great deal more pores than it does matter; a great deal more than is necessary for the passage of so infinitely fine and subtle a body as light.

Aristotle, Des Cartes, &c. place transparency in the rectitude or straightness of the pores, by means of which, say they, the rays are enabled to make their way through, without striking against the solid parts, and being reflected back again. But this account, Sir Isaac Newton shews, is lame: the quantity of pores, in all bodies, being sufficient to transmit all the rays that fall on them, however those pores be situated with respect to each other.

The cause, then, why all bodies are not transparent, must not be ascribed to their wanting rectilinear pores, but either to the unequal density of the parts, or to the pores being filled with some foreign matter, or their being quite empty; by means of which, the rays passing through, undergoing a great variety of reflections and refractions, are perpetually diverted this way and that, till at length falling on some of the solid parts of the body, they are extinguished and absorbed.

Thus cork, paper, wood, &c. are opaque, whereas glass, diamonds, &c. are transparent; the reason is, that in the neighbourhood of parts equal in density, such as those in glass, water, diamonds, &c. are, with respect to each other; the attraction being equal on every side, no reflection or refraction ensues; but the rays, which entered the first surface of the bodies, proceed, without interruption, quite through the body; these few only excepted, which chance to meet with the solid parts. But in the neighbourhood of parts that differ much in density, such as the parts of wood and paper are both in respect of themselves, and of the air, or the empty space in their pores; as the attraction will be very unequal, the reflections and refractions must be very great; and, therefore, the rays will not be able to make their way through such bodies, but will be perpetually deflected, and at last quite stopped.

TRANSPIRATION, the insensible, or almost insensible passage of an excrementitious matter thro' the pores of the skin, called also perspiration.

TRANSPIRATION is also used by some authors for the

ingress or entrance of the air, vapour, &c. through the pores of the skin into the body. Cardan, by this kind of transpiration, accounts for the prodigy of a woman whose daily urine weighed twenty-seven pounds, tho' all the food she took, both dry and liquid, did not exceed four pounds. Dr. Baynard also suspects some such transpiration to be the case in hydropical persons.

TRANSPLANTATION, in agriculture and gardening, the act of removing trees or plants from the places where they were sowed, or raised, and planting them in others. See PLANTING.

TRANSPLANTATION, in natural magic, is used for a method of curing diseases by transferring them from one subject to another, which was much in vogue among certain chemical or rather sympathetical physicians some years ago. A subject too whimsical to deserve further notice.

TRANSPORTATION, the act of punishment, or more properly an alleviation or commutation of punishment, for criminals convicted of felony, who for the first offence, unless it be an extraordinary one, are generally transported to the Plantations, there to bear hard labour for a term of years; within which, if they return, they are executed without farther trial.

TRANSPORTATION of Plants. In sending plants from one country to another, great cautions are necessary. The plants sent from a hotter country to a colder, should be always put on board in the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter should be sent in the beginning of winter. The best way of packing up plants for a voyage, if they be such as will not bear keeping out of the earth, is to have boxes with handles, filling them with earth, and planting the roots as close together as may be: the plants should be set in these boxes three weeks before they are to be put on board, and in good weather they should be set upon the deck, and in bad removed and covered with a tarpaulin.

If they are going from a hotter country to a colder one, they must have very little moisture; if on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

A great many plants, however, will live out of the earth a great while; as the sedums, euphorbiums, ficoides, and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between them, to prevent them from wounding or bruising one another, and holes bored on the boxes to keep them from heating and putrifying. In this manner they will come safe from a voyage of two, or three, or even four or five months.

Several trees also will come safely in the same manner, taking them up at a season when they have done growing, and packing them with moss. Of this sort are oranges, olives, capers, jasmynes, and pomegranate-trees. These and many others are annually thus brought over from Italy; and, though they are three or four months in the passage, seldom miscarry. The best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin. *Miller's Gard. Dict.*

TRANSPOSITION, in algebra, the bringing any term of an equation over to the other side.

TRANSPOSITION, in grammar, a disturbing or dislocating of the words in a discourse, or a changing of their natural order of construction, to please the ear by rendering the contexture more easy, smooth, and harmonious. A transposition which renders the sense perplexed, is vicious. The constitution of the ancient languages, being much more artful than that of the modern ones, allowed of much greater and more frequent transpositions. The English, French, &c. scarce ever allowed of them but in oratory and poetry, in which cases they serve to give a force and energy to the discourse or the verse, and to prevent their languishing.

TRANSPOSITION, in music, is a changing of the notes of a piece of music, or the shifting a song from its former situation, to set it either higher or lower, or in another octave.

Of this there are two kinds: the first is with respect to the clef, the second with respect to the key. Transposition, with respect to the clef, consists in the changing the places or seats of the notes or letters among the lines and spaces, but so as that every note is set at the same letter. This is done either by removing the same clef to another line, or by using another clef, but with the same signature, by reason the piece is in the same key.

The practice is easy in either case. In the first you take the first note at the same distance, either above or below the clef-note, in its new position, as before, and all the rest of the notes in the same relations or distances from one another, so that the notes are all set on lines and spaces of the same name. In the second, or setting of the music to a different clef, it is to be observed the places of the three clef-notes are invariable in the scale, and are to one another in these relations, the mean a fifth above the bass, and the treble a fifth above the mean. Now to transpose a new clef, for example, from the treble to the mean, wherever the new clef is set, we suppose it the same individual note in the same place of the scale, as if the piece were that part in the composition to which the new clef is generally appropriated, so that it may direct to the same notes we had before transposition. Now from the fixed relations of the three clefs in the scale, it will be easy to find the seat of the first transposed note, and then all the rest are to be set at the same mutual distances they were at before. Suppose, for example, the first note of a song be *d*, a sixth above the bass clef; wherever that clef is placed, the first note must be a greater second above it; because a greater second above the mean, is a greater sixth above the bass-clef, the relation between the two being a fifth: so that the first note will still be the same individual note *d*. The use of this transposition is, that if a song be set with a certain clef in a certain position, the notes go far above or below the system of five lines, they may, by the change of the place of the same clef in the particular system, or by taking a new clef, be brought more within the compass of the lines.

Transposition from one key to another, is the changing of a key, or a setting all the notes of a song at different letters, and performing it consequently in different places upon the instrument.

The design hereof is, that a song which being begun in one place is too high, too low, or otherwise inconvenient for a certain instrument, may be begun in another place, and from that carried on through all its just degrees. The clef and its positions here remain the same, and the change is of the notes themselves, from one letter, and its line or space, to another. In the former transposition the notes were expressed by the same letters, but both removed to different lines and spaces; in this the letters are unmoved, and the notes of the song transferred to or expressed by other letters, and consequently set upon different lines and spaces, which therefore requires a different signature of the clef.

TRANSUBSTANTIATION, *Transubstantiatio*, in theology, the conversion or change of the substance of the bread and wine in the eucharist, into the body and blood of Jesus Christ, which the Romish church hold it wrought by the consecration of the priest. This is a main point in the Romish religion, and is rejected by the protestants, the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text *hoc est corpus meum*, "This signifies my body:" but the council of Trent stood up strenuously for the literal sense of the verb *est*, and say expressly, that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially under the species of bread and wine. The controversies about this point, are almost innumerable.

TRANSUMPTION, *Transumptio*, in the schools, a syllogism by concession or agreement, used where a question proposed is transferred to another; with this condition, that the proof of this latter should be admitted for a proof of the former.

TRANSVERSALIS, in anatomy, a name given to several muscles, &c. in respect to their situation, pro-

gress, &c. as, 1. The transversalis abdominis, a muscle which lies under the obliqui, and arises from the cartilago xiphoides, from the extremities of the false ribs, from the transverse apophysis of the vertebræ of the loins, is fixed to the inner side of the spine of the ileum, and inserted in the os pubis and the linea alba. This, with the obliqui, unites its tendons as it approaches the linea alba, and is the only muscle that is cut in the operation of the bubonocoele. It has a fine and thin membrane, that closes exactly its ring or hole through which the vessels pass. 2. Transversalis colli, is said to be a part of the longissimus dorsi. It arises from the os sacrum, and from all the transverse processes of the vertebræ of the loins, back and neck, except the two first; and is inserted by so many distinct tendons into all the superior spines. It moves the whole spine obliquely backwards. 3. Transversalis pedis placentini, comes from the bone of the metatarsus that sustains the toe next the little toe, and passing across the other bones, is inserted into the os sesamoides of the toe. Its use is to bring all the toes close to one another. 4. Transversalis penis, one of the dilators of the urethra, arising from the tubercle of the os ischium on each side, and inserted into the posterior part of the bulb of the urethra; however, these muscles are not quite determinate and certain in their origin or insertion, and sometimes they are wholly wanting: when they act, they dilate the urethra in its posterior part. 5. Transversalis is also a name given to a suture of the cranium, because of its traversing or crossing the face from one side to another.

TRANSVERSE, something that goes across another from corner to corner: thus bends and bars, in heraldry, are transverse pieces or bearings: the diagonals of a parallelogram or a square, are transverse lines: lines which make intersections with perpendiculars, are also called oblique or transverse lines.

TRANSVERSE AXIS, or **DIAMETER**, called also the first or principal axis.—The transverse axis of an ellipsis is the longer axis, or that which traverses it lengthwise, in contradistinction from the conjugate one.

TRAPEZIUM, in geometry, a plane figure contained under four unequal right lines. 1. Any three sides of a trapezium taken together, are greater than the third. 2. The two diagonals of any trapezium, divide it into four proportional triangles. 3. If two sides of a trapezium be parallel, the rectangle under the aggregate of the parallel sides, and one half their distance is equal to that trapezium. 4. If a parallelogram circumscribes a trapezium, so that one of the sides of the parallelogram be parallel to a diagonal of the trapezium, that parallelogram will be the double of the trapezium. 5. If any trapezium has two of its opposite angles, each a right-angle, and a diagonal be drawn joining these angles; and if from the other two angles be drawn two perpendiculars to that diagonal, the distances from the feet of these perpendiculars to those right-angles, respectively taken, will be equal. 6. If the sides of a trapezium be each bisected, and the points of bisection be joined by four right lines, these lines will form a parallelogram, which will be one half of the trapezium. 7. If the diagonals of a trapezium be bisected, and a right line joins these points, the aggregate of the squares of the sides is equal to the aggregate of the squares of the diagonals, together with four times of the square of the right line joining the point of bisection. 8. In any trapezium, the aggregate of the diagonals is less than the aggregate of four right lines drawn from any point, except the intersection of the diagonals, within the figure.

TRAPEZIUS, in anatomy. See **CUCULARIS**.

TRAPEZOID, is a solid irregular figure, having four sides not parallel to one another.

TRAVERSE, or **TRANSVERSE**, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

Hence, to traverse a piece of ordnance, among gunners, signifies to turn or point it which way one pleases, upon the platform.

In fortification, traverse denotes a trench with a little parapet, or bank of earth, thrown perpendicularly across the moat, or other work, to prevent the enemy's cannon from

from raking it. These traverses may be from twelve to eighteen feet, in order to be cannon proof, and their height about six or seven feet, or more, if the place be exposed to any eminence. And to preserve a communication, a passage of about five or six feet wide must be left at one end of the traverse.

If any part of a work, thus shut in by one or more traverses, is likely to be defended by the musketry, it will be proper to add to the traverses one or more foot-banks within the defence, for the troops to mount on, when they want to fire over the traverse.

TRAVERSE, in navigation, is when a ship, upon the shifting of winds, sails upon several courses, in any given space of time. To resolve a traverse, is to order and compound the several courses and distances obtained by the log and compass, that the mariner may know, at all times, the place the ship is in, and be able to determine how far, and upon what course he must sail to gain his intended port.

Exam. Suppose a ship, in the latitude of 4 deg. 10 min. north, 3° 39' E. long. sails S. 11° W. 91 miles, S. W. 120 miles, W. N. W. 130 miles, S. E. 135 miles, S. E. by E. 130 miles, and S. W. by S. 150 miles; required the direct course and distance sailed, and the latitude and longitude the ship is in?

Geometrically. Draw the meridian line px (plate CXXXI. fig. 9.) and make the angle $qp2$ equal to 11° 15' = 1 point, and draw the right-line qp , making it equal to 88 miles, the first distance sailed, and let fall the perpendicular $q2$; then will q be the place of the ship, $p2$ the difference of latitude, and $q2$ the departure belonging to the first course: And after the same manner must the triangles $q3r$, $rs4$, $4t5$, $5u6$, and $67w$, be projected; then will w be the place of the ship at the end of her sailing, px the difference of latitude, wx the departure, the angle xpw her direct course from her first to her last station, and pw her direct distance; which may be all measured by the instructions given under the article *Plane SAILING*.

Arithmetically. The arithmetical solution of this problem depends entirely on the first and fourth cases of *Plane SAILING*; for first the corresponding difference of latitude and departure must be found to each course and distance, as in the first case, and placed in a table according to their several directions: That is, when the ship sails to the northward, the difference of latitude must be placed in the north column, but, when to the southward, in the south column; and the departure, if she sails to the westward, in the west column, but if to the eastward, in the east column. Then will the totals of the several columns shew the northings, southings, eastings, and westings the ship has made. And, consequently, if the southings exceed the northings, the ship will be to the southward of her first station, and just as much as is the excess, and *vice versa*; in like manner, if the eastings exceed the westings, the ship will be to the eastward of her first meridian, but, if the contrary, to the westward. Then we shall have the whole difference of latitude and departure from the meridian given, to find the course and distance as in the fourth case. See the following table:

Courses.	Distances.	Diff. of Lat.		Departure.	
		North-ings.	South-ings.	East-ings.	West-ings.
South 11° west	91		89,3		17,2
South-west	120		84,8		84,8
West-north-west	130	49,8			120,1
South-east	135		95,4	95,4	
South-east by east	130		73,3	108,0	
South-west by S.	150		124,7		83,4
		49,8	467,5	203,4	305,5
			49,8		203,4
		Diff. Lat. 417,7		Depart. 102,1	

Hence, it appears, that the ship is 417,7 miles to the southward of her first station, and 102,1 miles to the

westward of her first meridian; whence we may, by the fourth case of plane sailing, find her direct course and distance, as follows:

1. As the difference of latitude $px=417,7=2.6208645$
Is to the radius ——— = 90d. 00m. = 10.0000000
So is the departure wx ——— = 102,1 = 2.0090257

To the T. of the course or angle $wpx=$ } 9.3881612
13d. 44m. = ———

Which is south 13d. 44m. westerly, or something more than south by west, because the difference of latitude is southerly, and the departure westerly.

2. As the sine of the course — = 13d. 44m. = 9.3760034
Is to the departure ——— = 102,1 = 2.0090257
So is the radius ——— = 90d. 00m. = 10.0000000

To the distance ——— = 429,6 ——— = 2.6330223

And, because the difference of latitude exceeds the latitude sailed from, d. m.

Therefore, from the diff. of latitude = 417,7 = 6: 57,7

Take the latitude sailed from ——— = 4: 10 N.

Remains the latitude the ship is in ——— = 2: 47,7 S.

And, because the difference of long. is westerly, therefore, d. m.

From the longitude sailed from ——— = 3: 39 east.

Take the difference of longitude = 102,1 = 1: 42,1 west.

Remains the longitude the ship is in ——— = 1: 47,9 east

Hence it appears, that the ship is arrived in the latitude of 2d. 47,7m. = 2d. 47m. 42f. south, and 1d. 47,9m. = 1d. 47m. 54f. east longitude; her direct course from her first to her last station being south, 13d. 44m. westerly, distant 429,6 miles.

TRAVERSE, in law, denotes the denial of some matter of fact alledged to be done in a declaration, or pleadings: upon which the other side coming and maintaining that it was done, issue is joined for the cause to proceed to trial.

TRAVERSE of an *Indictment*, or *Presentment*, is the contradicting or denying some chief point of it, and taking issue thereon.

TRAVERSE of an *Office*, is the proving that an inquisition made by lands or goods, is defective and untruly made.

TRAVERSE is sometimes also used, in heraldry, for a partition of an escutcheon, which is blazoned parti per pale traverse, argent and gules.

TRAVESTY, or TRAVESTI, a French term, derived from the verb *travestir*, to disguise one's self, or to appear in masquerade: and hence, travesty is applied to the disfiguring of an author, or the translating him into a style and manner different from his own, by which means it becomes difficult to know him.

TRAUMATICS, the same with vulnerary medicines. See VULNERARY.

TREACLE, *Theriaca*, in pharmacy. See the article THERIACA.

Some also give the name treacle to melasses; and in this sense it is that Dr. Shaw, in his *Essay on Distillery*, has endeavoured to bring into use several sorts of treacles, which might be made at home, and would serve very conveniently for the distillation of spirits, or the making of potable liquors. These are the inspissated juices or decoctions of vegetables: such as the sweet juice of the birch, or sycamore, procured by tapping or piercing the trees in spring, and the common wort made from malt, or from other vegetable substances treated in the same manner. These liquors are severally to be boiled down in a copper till they begin to inspissate, and then to be poured into a balneum mariæ, when the remainder of the evaporation may be finished without burning the inspissated juices: thus prepared it may be at any time reduced to the state of wort, only by adding a sufficient quantity of warm water.

TREASON, in general, signifies betraying; but is more particularly used for the act or crime of infidelity to one's lawful sovereign.

Treason is divided, by lawyers, into high treason and petty treason. The first of these is an offence committed against the security of the king or kingdom; as to compass,

or imagine, the death of the king, queen, or their eldest son and heir; or in case a person does violate or deflower the king's wife, or his eldest daughter unmarried, or the wife of the king's eldest son; or if he levy war against the king within his kingdom, or adhere to his enemies, give them aid or comfort within the realm, or elsewhere; or if he counterfeit the king's great or privy seal, or his money, or bring false money into the kingdom, like to what we have here, and utter the same; if he kill the chancellor, treasurer, justices of either bench, justices of assize, or of oyer and terminer, sitting in judgment and representing the person of the king, in the execution of his office: all these cases are deemed treason by 25 Ed. III. c. 2. which statute is made the only standard of high treason; and 1 Mary c. 1. takes away the power of the king and parliament to adjudge any thing else to be high-treason but what is declared to be such therein: it is true, temporary statutes of late times enacted, have made some other offences treason, as relating to papists and the protestant succession.

It has been held, that words only, where they are deliberate, and shew a direct purpose against the king's life, will amount to an overt-act of compassing or imagining his death, and are high-treason: for words are the most natural way of expressing the imagination of the heart, and may be good evidence of it: not only words of persuasion to kill the king, but such as are spoken in order to draw away the affections of his people, and to stir them up against him, are tending to the king's death, and therefore treason. Likewise where a person intends by force to prescribe laws to the king, or to restrain him of his royal power, it has been adjudged an intention to deprive him of his crown and life; and in the eye of the law, every rebellion is a treasonable plot against the life of the king, for a rebel would not suffer that king to live and reign, who would punish his offence.

As to make a crime treason, there must be always some overt-act; a bare conspiracy, or compassing to levy war, is no such act, unless it be really levied; in which case the conspirators are all traitors, although they are not in arms: persons that raise forces for any public end or purpose, or who make an insurrection on any account, are said to levy war against the king, though perhaps without a direct design against his person; and it extends to the case where great numbers forcibly endeavour to remove certain persons from the king, &c. The adhering to the king's enemies, is taken to be an adherence against him, and even out of the realm it is treason: and it is said, that cruising in a ship of war with an intent to destroy the king's ships, though no act of hostility be committed, is an overt-act of adhering, comforting and aiding.

All trials for high-treason are to be according to the course of the common law; and persons indicted for this crime, are to have a copy of the indictment five days before their trial, that they may have sufficient time to advise with council; they shall likewise be permitted to make a full defence by their council learned in the law, and by lawful witnesses, &c. And in this case there must be two evidences to the same overt-act, or to two acts of the same treason, produced face to face against them. It is also said, where a person is convicted of treason, the omission of any necessary part of the judgment will be held to error, on which he may reverse the attainder; as the judgment is severer, and more formidable, in case of high-treason than for any other crime whatever; since the offender is to be hanged, drawn, and quartered, and also forfeit his lands and goods to the king.

Petty treason, is where a servant kills his master, a wife her husband, or a secular or religious person kills his prelate or superior, to whom he owes faith and obedience, and aiders and abettors, as well as procurers, are within the act. However, so strictly is the statute construed, that no case not expressly mentioned therein is punishable by it: hence if a son kill his father, he shall not be tried for petty treason, except he served his father for wages, in which case he is to be indicted under the name of a servant.

Petty treason implies the highest degree of murder, and occasions the forfeiture of lands by escheat to the lord of the fee: and the further punishment of the criminal is to be hanged, drawn, and quartered for it, and a woman burnt.

TREASURE, in general, denotes a store or stock of money in reserve.

TREASURE-TROVE, in law, is where any treasure is found buried in the earth, but not lying on the ground, and no man knows to whom it belongs: this, in England, belongs to the king, and to conceal it is punishable by fine and imprisonment.

TREASURER, an officer to whom the treasure of a prince, or corporation, is committed to be kept, and duly disposed of in payment of officers, and other expences.

Lord high TREASURER of England, is the third great officer of the crown, under whose charge and government is all the king's revenue kept in the Exchequer.

He receives the office by the delivery of a white staff to him from the king, and holds it during the king's pleasure; anciently he received it by delivery of the golden keys of the treasury. He has the check of all the officers any way employed in collecting imposts, customs, tributes, or other revenues of the crown. He has the gift of all the customers, comptrollers, and searchers of places in all the ports of London, and the nomination of the escheators in every county.

He alone, or others in commission with him, letteth leases of all the crown lands, gives warrants to certain persons of quality to have their wine custom free, &c.

TREASURER of the *Household*, is an officer who, in the absence of the lord steward, has power with the comptroller and other officers of the Green-cloth, and the steward of the Marshalsea, to hear and determine treasons, felonies, and other crimes committed within the king's palace.

TREASURER of the *Navy*, is an officer who receives money out of the Exchequer, by warrant from the lord high treasurer, or the lords commissioners executing that place, and pays all charges of the navy by warrant from the principal officers of the navy.

TREASURY, the place wherein the revenues of a prince are received, preserved, and disbursed.

In England, the Treasury is part of the Exchequer, by some called the lower Exchequer.

Lords of the TREASURY.—In lieu of one single director and administrator of his majesty's revenues under the title of lord high treasurer, it is frequently thought proper to put that office in commission, that is, to appoint several persons to discharge it with equal authority, under the title of lords commissioners of the Treasury.

TREATISE, *Traclatus*, a set discourse in writing on any subject. A treatise is supposed more express, formal, and methodical than an essay, but less so than a system.

TREATY, a covenant between two or more nations; or the several articles or conditions stipulated and agreed upon between sovereign powers.

TREBLE, in music, the highest or acutest of the four parts in symphony, or that which is heard the clearest and shrillest in a concert.

TREE, *Arbor*, the first and largest of the vegetable kind, consisting of a single trunk, out of which spring forth branches and leaves.

Standard-trees are such as naturally rise to a great height, and are not topped. For the choice of trees of this kind to be transplanted out of a nursery, Quintiney recommends us to such as are straight, six feet high at least, and five or six inches thick at bottom, and three or four at top; the bark pretty smooth and shining, as a token of their youth, and of the good soil they grew in.

Dwarf-trees are such as are kept low, and never suffered to have above half a foot or stem.

Fruit TREES. See the article FRUIT.

Heat is so essential to the growth of trees, that we see them grow larger and smaller in a sort of gradation, as the climates in which they stand are more or less hot.

The hottest countries yield in general the largest and tallest trees, and those also in much greater beauty and variety than the colder do; and even those plants which are common to both arrive at a much greater bulk in the southern, than in the northern climates; nay, there are some regions so bleak and chill, that they raise no vegetables at all to any considerable height. Greenland, Iceland, and the like places, afford no trees at all; and what shrubs grow in them are always little and low. In the warmer climates, where trees grow to a moderate size, any accidental diminution of the common heat is found very greatly to impede vegetation; and, even in England, the cold summers we sometimes have, give us an evident proof of this; for though the corn and low plants have succeeded well enough, and gooseberries, currants, raspberries and other low shrubs, have brought forth fruit in sufficient plenty, yet the production of taller trees has been found very much hurt; and walnuts, apples, and pears, have been very scarce among us.

Heat is heat, be it from what cause it will, and acts as well upon vegetation one way as another. Thus the heat of dung, and the artificial heat of coal fires in stoves, is found to supply the place of the sun.

Great numbers of the Indian trees in their native soil flower twice in a year, and some flower and bear ripe fruit all the year round; and it is observed of these last, that they are at once the most frequent and most useful to the inhabitants; their fruit, which hang always on them in readiness, containing cool juices, which are good in fevers, and other of the common diseases of that hot country.

Plantations of useful trees might be made to very great advantage in many places in every country, and the country greatly enriched by it, while the public would be also benefited by it, since it would raise a continual supply of timber used in ship-building, and on other public as well as private occasions.

We have, in many places, heaths, and other barren and uncultivated lands, of very great extent; and how great an advantage would it be to the public, to bring these to be truly valuable? Many, if not all of these heaths, would be found on trial capable of producing trees; and some of them are truly the remains of destroyed forests; and, though the profits to be reaped from the planting these would come late, yet the expence of doing it would be very trifling in comparison of that profit, and the means easy.

The authors who have given rules for planting, having employed themselves only about small spots of ground, the establishing orchards, or parks, are by no means to be supposed proper guides in attempts of this kind; and Monsieur de Buffon, who had a great opinion of the knowledge of our Evelyn and Miller, who seem to speak of every thing from their own experience, found, when he set about large plantations, that their opinions and rules were erroneous; and was obliged to have recourse to experiments only; which he varied a thousand ways: and, though many of them proved unsuccessful, yet they all gave hints towards others, by which the attempt might afterwards be brought to succeed.

This sagacious enquirer into the operations of nature in the growth of vegetables, having set apart a considerable quantity of land for the trial, and procured a number of young trees, first divided the whole quantity into a number of small squares, and, having made a plan of it, examined the nature, depth, and other circumstances of the soil in each, and minuted the whole down on a proper part of the plan: that himself or whoever succeeded him might judge, from the different growths of a number of trees planted in the same state in the different soils, the different advantages and disadvantages of every circumstance in the depth and nature of the ground, in regard to the growth of useful trees. Different numbers of labourers were employed about different spots of this ground, and the acorns for the young growth planted at different seasons; but the result in general was, that what should seem the best methods succeeded the worst; and those pieces where many labourers were employed, and the acorns planted before winter, were much thinner of young oaks, than those where the least labour had been

bestowed upon the ground, and where the acorns had been planted in the spring; but those places which succeeded best from the sowing, were those which had the acorns planted in holes made by a pickaxe, without any preceding culture of the ground. And those where the acorns had only been laid upon the earth, under the grass, afforded a great number of vigorous young trees, though the greater part had been carried away by birds, and other devouring animals. Those spots of ground where the acorns were set six inches deep, were much worse furnished with young shoots, than those where they had been buried but at an inch deep; and in some places where they were buried at a foot deep, not one shoot appeared, though in others where they had been buried at nine inches there were many.

Those acorns which had been steeped for eight or nine days in wine lees, and in the water of the common sewers, appeared out of the ground much earlier than those which were put in without this previous management.

But the most successful of all the trials was that of planting in the spring such acorns as had been sown together in another place, and had time to shoot there; of these scarce any failed, and the plantation was perfectly flourishing, though the growth of these young shoots was not so quick and vigorous as those of the acorns which had remained, when first sown; which was probably owing to the injury the tender radicles received in transplanting.

Thus succeeded the experiments by sowing, while, of those made by planting young trees, such as had been brought out of woods, and places under covert, succeeded much worse than those which had grown in more exposed places.

The young trees of the several parts of the plantation kept on their growth in the manner they had begun to shoot, those of the more laboured parts continuing more weak, and lower than those of the less laboured.

Thus were a number of necessary experiments carefully tried, and the result of the whole was, that to make a plantation of oaks, on a soil of the common clayey or loamy kind, the most successful method is this: the acorns must be preserved during the winter in the earth in this manner; let there be made a bed of earth six inches deep, on this place a layer of acorns two inches deep, over these lay a bed of another half foot of earth, over that another layer of acorns, and so on successively, till as many are employed as there will be occasion for; the whole is then to be covered with a foot depth of earth, to preserve all from the frost. In the beginning of March, these beds are to be opened, and the acorns which will by that time have shot out, and are then in reality so many young oaks, are to be planted out at a foot distance each, and the success of a plantation of this kind need not be feared. This is a manner of planting that is done at a small expence, and even that might be in a great measure spared, were it not for the birds and other devouring animals; since, could the acorns be defended from these, they might be only laid on the surface of the ground under the grass in autumn, and they would infallibly shew themselves in so many young oaks the succeeding spring.

It is easy to continue the carrying the acorns, when taken out of their winter's bed, to the place where they are to be planted, without doing them much injury; and the small stop the transplanting puts to their growth, is in reality rather an advantage than an injury; since it only retards the young shoots for about three weeks, or less than that: and by that means secures them from the few cold mornings that may be expected about the time of their natural appearance.

For the planting, pruning, felling, grafting, &c. of trees, see the article PLANTING, PRUNING.

TREFOIL, *Trifolium*, in botany, a genus of plants, the flower of which has a tubulous permanent empalement of one leaf: it is of the butterfly kind, drying in the empalement. The standard is reflexed, the wings are shorter than the standard, and the keel is shorter than the wings; it has ten stamina, nine are joined, and one is separate, terminated by single summits; and an almost

oval germen supporting an awl-shaped style, crowned by a single stigma. The germen afterward becomes a short pod with one valve, containing a few roundish seeds.

Mr. Miller enumerates twelve different species of trefoil, the first of which is well known in England by the name of red clover; and the manner of cultivating this plant has been already described under the article CLOVER.

The second sort, namely, the white Dutch clover, grows naturally in most of the pastures in England, and is generally known among the country people by the name of white honey-suckle.

This is an abiding plant, whose branches trail upon the ground, and send out roots from every joint, so that it thickens and makes the closest sward of any of the sown grasses; and it is the sweetest feed for all sorts of cattle yet known: therefore when land is designed to be laid down for pasture, with intent to continue so, it should be sown with the seeds of this plant. The usual allowance of this seed is eight pounds to one acre of land; but this should never be sown with corn, for if there is a crop of corn, the grass will be so weak under it, as to be scarce worth standing; but such is the covetousness of most farmers, that they will not be prevailed on to alter their old custom of laying down their grounds with a crop of corn, though they lose twice the value of their corn by the poorness of the grass, which will never come to a good sward, and one whole season is also lost; for if this seed is sown in the spring without corn, there will be a crop of hay to mow by the middle, or latter end of July, and a much better after-feed for cattle the following autumn and winter, than the grass which is sown with corn will produce the second year. The seed of this sort may also be sown in autumn, and this autumnal sowing, if the seeds grow kindly, will afford a good early crop of hay the following spring; and if, after the hay is taken off the land, the ground be well rolled, it will cause the clover to mat close upon the ground, and become a thick sward.

The seeds of this white Dutch clover is annually imported from Flanders, by way of Holland, whence it received the name of Dutch clover; not that it is more a native of that country than of this, for it is very common in moist pastures, in every county in England: but the seeds were never collected for sowing in this country till of late years; nor are there many persons here, even now, who save this seed, though it may be done if the same method, as is practised for the red clover, be taken with this sort; it should therefore be recommended to every farmer, who is desirous of improving his land, to sow carefully an acre or two of this white clover for seed, which will save him the expence of buying for some years, when the price is great; and there will be a sure market for any quantity he may have to spare.

The third sort, namely hop-clover, called by some yellow meadow trefoil, grows naturally among the grass in the upland pastures of this country; but the seeds are frequently sold in the shops, and are by many mixed with the other sorts of clover and grass-seeds, for laying down ground to pasture. This plant grows with upright branching stalks about a foot high, garnished with trifoliate leaves, whose lobes are oblong and heart-shaped, but reversed, the narrow point joining the foot-stalks. The flowers, which are yellow, grow from the wings of the stalk, upon long foot-stalks, collected into oval imbricated heads, having naked empalements lying over each other like scales, somewhat like the flowers of hops, from whence the plant had the name of hop-clover. But there are two sorts of this clover, which grow naturally in England. The other is a much smaller plant than this, and generally known by the name of none-such, or yellow hop-trefoil.

The hop-clover is strongly recommended by the following circumstances. 1. It not only grows, but flourishes on the most barren sands, and therefore must be a very proper grass to cultivate on such unfertile soils, where any other grass that is worth notice will not grow at all. 2. It is not apt to swell cattle, as the red clover does. 3. In good ground it will continue long, and bear a very good feed or crop, as Mr. Tull, though prejudiced

against clovers, confesses; and, by its flourishing both on sands and clay, which have not been ploughed for many years, it seems likely to continue long in any soil.

The fifth sort grows naturally on chalky lands in many parts of England; and in some countries the seed is sown after the same manner as the common red clover, especially on chalky ground, where it will thrive, and produce a better crop than clover. The stalks of this are hairy, and grow erect to the height of two feet or more, garnished with trifoliate leaves, standing upon long foot-stalks, whose lobes are longer than those of the red-clover, and have no marks of white; they are of a yellowish green colour, and are covered with soft hairs. The flowers grow in oval spikes at the end of the branches; they are of a pale copper colour; their petals are long and tubulous, but the brim is divided into two lips, as the other sorts.

This is known by the title of trefoil, in the places where it is cultivated; but the seedsmen sell the hop-clover by that name, so they make no distinction between this, the hop-clover, and none-such; therefore, by which of these three titles the seeds are bought, they prove the same.

This sort of trefoil is much cultivated in that part of Essex which borders on Cambridgeshire.

The sixth sort grows naturally in Spain and Italy; this has upright stalks near two feet high, which are hairy, garnished with trifoliate leaves, having roundish lobes, which are sawed at their points. The flowers are produced at the top of the stalk in long, obtuse, hairy spikes, of a bright red colour, so make a pretty appearance during their continuance. It is an annual plant, so is not proper for sowing as fodder.

The seventh sort is an annual plant, which grows naturally in the south of France and Italy; it rises with a strong smooth stalk near three feet high, garnished with trifoliate leaves, whose lobes are two inches and a half long, and near a quarter broad, standing upon long foot-stalks, which are embraced by stipulæ or sheaths their whole length. The flowers are produced at the top of the stalks in very long spikes; they are of a beautiful red colour, so make a fine appearance. It flowers in July, and the seeds ripen in autumn.

The eighth sort grows naturally in Spain and Italy; this rises with a slender stiff stalk near two feet high, garnished with trifoliate leaves, whose lobes are very narrow and hairy. The flowers are produced at the top of the stalks in oblong conical spikes; the indentures of their empalements end in long bristly hairs, which are almost equal in length; the spikes are hairy, and the flowers of a pale red colour.

The ninth sort is the common hare's foot trefoil, which grows naturally upon dry gravelly land in most parts of England, and is a sure indication of the sterility of the soil, for it is rarely seen upon good ground. This plant is seldom eat by cattle, so is unfit for pasture, and is only mentioned here because it is sometimes used in medicine; it is an annual plant, whose root decays soon after it has perfected seeds.

The tenth sort grows naturally on arable land in many parts of England; this has trailing stalks, which put out roots at their joints. The leaves stand upon long slender foot-stalks; the lobes are roundish, and sawed on their edges; the flowers are collected in roundish heads, standing upon slender foot-stalks, which rise from the wings of the stalks; these have bladdery empalements, which terminate in two teeth. When these lie on the ground, their globular heads, having a little blush of red on their upper side toward the sun, and the other part being white, have a great resemblance of strawberries, and from thence it was called strawberry trefoil.

These sorts are preserved in botanic gardens for variety; they are easily propagated by seeds, which may be sown on an open bed of ground, either in autumn or spring.

The plants which come up in autumn, will grow much larger, and flower earlier in the summer than those which are sown in the spring, so from those good seeds may be always obtained, whereas the others sometimes miscarry.

When the plants come up, they require no other care than to keep them clean from weeds, and thin them where they are too close.

The eleventh sort is the common melilot, which is used in medicine, and has been already described under the article MELILOT, which see.

The twelfth sort grows naturally in Bohemia and Austria, but has been long cultivated in England as a medicinal plant, though at present it is rarely used; it is annual. The stalks are large, hollow, and channelled; they rise about a foot high, garnished with trifoliate leaves, whose lobes are oval, and slightly sawed on their edges, standing upon pretty long foot-stalks. The flowers are collected in oblong spikes, which stand upon very long foot-stalks, springing from the wings of the stalk at every joint; they are of a pale blue colour shaped like those of the common melilot; these appear in June and July, and are succeeded by small yellow seeds, of a kidney shape, two or three being included in each short pod. The whole plant has a very strong scent like that of fenugreek, and perishes soon after the seeds are ripe. *Miller's Gard. Dict.*

TREMOR, or TREMBLING of the Joints, in medicine, is an involuntary shaking, chiefly of the hands and head, sometimes of the feet, and sometimes of the tongue and heart. It is a disorder which frequently attacks persons advanced in years, and sometimes the younger sort. It seems to arise from a defect of spirits, sometimes from terror, or other violent passion, and sometimes from a plethora. Too much drinking of coffee also produces a tremor in some persons, as too plentiful drinking and surfeits will in others.

Tremors are often dangerous, as being apt to degenerate into other nervous distempers; as spasms, the palsy, lethargy, apoplexy, &c.

In the cure, those things should be avoided that promote the disease, and the patient should drink balm or sage-tea, or a diet-drink made of China-root. Peruvian bark may also be taken, in an infusion of balm or sage, or succinated spirit of hart's-horn, twice or thrice in a day; and in the evening an antispasmodic powder may be taken, especially if the patient is hot, or uses much wine. Outwardly, the neck and spine of the back may be rubbed with the spirits of ants, earth-worms, and sal ammoniac, mixed together; a fourth part of the volatile spirits will be sufficient, or opodeldoc may be used in their stead. If the patient is plethoric, bleeding is useful; and in old persons, a draught of generous wine at meals: pediluvia, hot-baths, and mineral-waters, may also be used, but with caution.

As to the medicine commonly used in tremors and other nervous distempers, under the name of palsy-drops, it is no other than compound spirit of lavender; the most successful way of using which is, by taking thirty or forty drops twice or thrice a day, dropped on loaf-sugar or a little bread. It is supposed that by this way the most spirituous and efficacious parts make their way directly by the nerves of the palate, &c. without undergoing the course of the circulation, as it is said to do when taken in a liquid vehicle.

TRENCHES, in fortification, are ditches cut by the besiegers, that they may approach more securely to the place attacked: whence they are also called lines of approach. The tail of the trench is the place where it was begun, and its head is the place where it ends.

The trenches are usually opened, or begun, in the night-time; sometimes within musket-shot, and sometimes within half or whole cannon-shot of the place.

They are carried on in winding-lines, nearly parallel to the works of the fortrefs, so as not to be in the view of the enemy, nor exposed to the enemy's shot.

The workmen employed in the trenches are always supported by a number of troops, to defend them against the sallies of the besieged: the pioneers sometimes work on their knees, and are usually covered with mantlets or saucissons; and the men who support them lie flat on their faces, in order to avoid the enemy's shot.

TREPAN, *terebra, modiolus*, &c. in surgery, an instrument used in trepanning.

TREPANNING, in surgery, a perforation, or opening, made in the bones of the cranium.

This operation was performed by the antients, not only in fractures and depressions of the cranium, but also in those other obstinate disorders of the head and brain, which could not be relieved by internal medicines and the use of issues upon the coronal suture; but the modern surgeons never use the trepan for internal disorders of the head, though they seldom neglect it in fractures and depressions of the cranium.

The trepan is therefore useful not only in these cases, to elevate the depressed parts of a fractured bone in the cranium, but also to discharge the extravasated blood through an aperture made by this instrument.

The less time there is lost the better before the application of the trepan, but the operation itself must be conducted slowly and carefully; for it is extremely difficult, if not impossible, to take out a piece of the cranium by this instrument without injuring the subjacent dura mater, to which it is most intimately attached. For this reason Heister is induced to condemn the advice of those who direct to trepan the cranium immediately upon every slight disorder of it: he therefore advises first to try the use of other remedies, both external and internal, rather than immediately subject the patient to the trepan, before it is absolutely necessary. In general, the place where the fissure appears will be the most convenient to apply the trepan, if nothing indicates the contrary: but in fractures it will be proper to trepan a little below the injured part, that the extravasated blood may be more easily discharged. It must be next observed, that there are several places in the cranium which ought not to be in any case trepanned; such as, 1. upon the sutures, especially the sagittal suture; yet in cases of urgent necessity, the trepan may be used upon the coronal sutures, and sometimes upon the others. 2. It is equally dangerous to trepan the cranium in the middle of the os frontis, especially in that part which forms the fontanel. 3. The trepan must not be used upon any of the sinusses of the os frontis. 4. Nor ought it to be used where any large vein or artery spreads itself. 5. If the fractured part of the bone upon which you fix the trepan is loose, or carious, you might then injure the brain by this instrument. 6. It will be improper to trepan in the lower parts, or basis, of the cranium, which are invested with muscles. 7. Lastly, it will be improper to trepan upon the cruciform eminence of the os occipitale. Notwithstanding these cautions, if a violent fracture should happen in or near these parts, you should trepan as near them as possible; and if the fracture has passed across the sutures, you must trepan within a finger's breadth of the suture on each side. Sometimes it is impossible to discover the particular part of the cranium which is injured, the patient in the mean time being affected with the most dangerous and urgent symptoms. In these cases it will be necessary to trepan first on the right side, then on the left, afterwards upon the forehead, and lastly upon the occiput, and so round till you meet with the seat of the disorder.

After having pitched upon the part to be trepanned, your next business is to shave the scalp, and make an incision through the integuments to lay bare the cranium, except it be done already by the wound.

The incision of the integuments may be made in the form of a cross, or of the letters X, V, or T, large enough to admit the crown of the trepan upon the bone. The wound may be enlarged, and the hæmorrhage stopped, after the integuments and periosteum are separated and elevated from the cranium, by inserting a large quantity of scraped lint. Next a compress dipped in warm camphorated spirit of wine must be applied and retained by the kerchief bandage. Then the patient is to be left, if the disorder will permit, for a few hours, that the blood may be stopped before the trepan is applied. Among the apparatus, or instruments and dressings, which must be provided before the operation is entered upon, the first and principal is the trepan with its crown, (plate CXXXI. fig. 10.) made in the shape of a common gimblet with a handle turning round. The crown of this instrument, marked A, is joined to the lower part of the handle, B, by a screw, so that it may be taken off and put on at pleasure, or else that a crown of another size may be screwed in its place. The trepan

pan is distinguished into male and female; in the first of which the crown is furnished with a sharp point E, but when the said point, or pyramid *fig. 11.* is taken out by the winch, *fig. 12.* the trepan is then termed female. You must also be provided with a scalpel of a particular make, with a round and flat head, as represented in *fig. 13.* which is denominated the lenticular scalpel; to which is added another instrument for gradually depressing the dura mater, of the shape represented in *fig. 14.* There must be also a perforating instrument provided, *fig. 15.* which must be screwed into the cavity B of the handle *fig. 10.* also a hair-brush and an elevatory.

The apparatus of dressing and bandage, to be applied after the operation, consists of a dossil of lint, of an orbicular figure, which must be tied round the middle with a piece of thread about a span long; there must be pledgets of lint for covering the other dressings, and filling up the cavity of the cranium, &c.

The apparatus being thus provided, in order to perform the operation with greater readiness and exactness, the patient must be disposed in such a convenient posture that the surgeon and assistants may have free access to perform each their part. Then the dressings being removed, the wound is to be cleansed; after which, the head being placed in a convenient manner upon a pillow, the surgeon takes the perforating trepan, *fig. 15.* and adapting it to the handle B, *fig. 10.* instead of the crown A, so that by turning round the handle D, he makes a full entrance, or aperture, with his instrument, and then applies the male trepan, with a crown A, *fig. 10.* Upon the top of the handle C C, the surgeon fixes his left hand, upon which he places his chin or forehead, while with his right he slowly and carefully turns round the handle till the crown of the trepan with its spindle have made a circular entrance deep enough in the cranium, and then he removes the spindle, and continues his work with the crown of the trepan only as long as he sees convenient; all the saw-dust being first brushed off from the cranium, and the teeth of his instrument, with the brushes. He now continues to use the trepan till the saw-dust becomes bloody, which denotes that he has penetrated the diploë: however, he may not always meet with this sign, because in some skulls the diploë may be wanting in the part trepanned; but when the saw-dust becomes bloody, the instrument is to be laid aside: and after washing away the blood with a sponge dipt in spirit of wine, he then screws the elevatory, by two or three turns, into the small aperture in the middle of the trepanned piece of the bone, and takes it out again, making two or three more turns with the crown of his trepan: then he examines with a probe, whether the plates of the cranium are sufficiently sawed through, which cannot be better known than by attending to the colour of the circular groove; for when that appears blue or grey, it is a sign that you have penetrated through the lower plate of the bone, so far as to render the dura mater almost conspicuous through it; but if the bony plate appears livid in one part of the circular groove, and white in another, it is a sign that the trepan has not cut equally through, and therefore it must be inclined and pressed a little harder upon the whitest parts, moving round the handle till the saw-teeth of the crown have cut deep enough to make the round piece of the bone loose or moveable. In that case it will not be convenient to cut totally through the bone with the saw-teeth of the trepan.

Having thus extracted the round piece of the cranium, the blood usually follows it: which being wiped off, the surgeon is to examine whether there be any fragments remaining to be extracted and loosened; for then you must smooth the rough parts about the lower margin of the aperture, by applying the scalpel, *fig. 13.* to prevent the dura mater from being pricked and injured by any of the sharp splinters. This done, the blood will more readily discharge itself, but to promote its exit you may gently incline the patient's head to one side, and another tenderly pressing the dura mater itself, either by the hand of the scalpel, or the depressor, *fig. 14.* by which means the patient is no sooner relieved from the pressure of the extravasated blood on his brain, but he instantly begins to recover his senses; the surgeon should then direct him

to fetch a deep breath, or hold it with a strain, like one that has a hard stool.

The dressings and deligation are to be made with a round pledget of dry lint laid next the dura mater, with a thread fastened to it, and hanging out of the aperture, that it may be placed under, and drawn out from beneath the cranium; upon which pledget is afterwards poured some honey of roses diluted with a little spirit of wine: you then impose a like pledget of lint, furnished with a string with other dossils, till the cavity is replete: and, in the next place, the cranium, and wound itself, is to be dressed with lint, spread with some digestive ointment, upon which add a square compress dipt in warm spirit of wine, and then secure the whole without a plaster, by the head bandage. In the subsequent dressings, which must be repeated once or twice every day, you must avoid fat and oily applications.

The wound being constantly attended, you will have an exfoliation of a thin plate from the trepanned margin of the bones, usually within forty or fifty days, which ought not to be pulled away by force. The exfoliation being obtained, there will appear new flesh and callus shooting up from the clean bone and dura mater, so as at length to fill up the whole cavity.

That instrument called the exfoliating trepan, is sometimes used to pare away a carious part in a bone. It is represented in *fig. 16.* and when used is to be screwed into the handle B of *fig. 10.* in order to be turned round: A is its point: B B the wings, which scrape the bone while the instrument is turning about.

TREPIDATION, in medicine, the same with tremor. See TREMOR.

TREPIDATION, in the ancient astronomy, denotes what they call a libration of the eighth sphere, or a motion which the Ptolemaic system attributed to the firmament, to account for certain almost insensible changes and motions observed in the axis of the world, by means of which the latitudes of the fixed stars come to be gradually changed, and the ecliptic seems to approach reciprocally first towards one pole, then towards the other. This motion is called the motion of the first libration.

TRESPASS, in law, signifies any transgression of the law under treason, felony, or misprision of treason.

TRESPASS, however, is commonly used either for that wrong or damage which is done to the king in his forest, or by one private man to another.

TRESSURE, in heraldry, a diminutive of an orle, usually held to be half the breadth thereof.

TRET, in commerce, an allowance made for the waste, or the dirt, that may be mixed with any commodity, which is always four pounds in every one hundred and four pounds weight.

TRIA PRIMA, among chemists, the three hypostatical principles, viz. salt, sulphur, and mercury; of which they hold all bodies to be primarily made, and into which they are all held resolvable by fire.

TRIAL, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge: or, it is the manner and order observed in the hearing and determining of causes.

There are divers kinds of trials; as those of matters of fact, which must be tried by a jury; matters of law, which are only triable by the courts; and matters of record, which are to be tried by the records themselves. The most general rule has been, that the jurymen on a trial shall be chosen out of that town or precinct, &c. in which the matter of fact is alledged, or the nearest thereto, for the better cognizance of the matter, and not to leave things to be tried in foreign countries, where the jury are strangers to the whole matter. Where any trial is for murder, it must be in the county wherein the fact was committed; but if the assault be in one county, and the person assaulted happens to die in another county, the indictment may be found by a jury of the county where the party died: and by special commission, when a person is indicted in one county, he may be tried in another. In all criminal cases the custom is to ask the prisoner how he will be tried, which was formerly a very significant question, though it is not so now, because antiently there were trials by combat, by ordeal, and by jury; and

and when the prisoner answered, by God and his country, it appeared he made choice to be tried by a jury; which is the only way now used for the trial of criminals.

The method of proceeding in criminal cases is this: first the bill of indictment against the offender is prepared, and the prosecutor and his witnesses attend on the grand jury therewith, and there give in their evidence; which being done, the grand inquest either find the bill of indictment, or bring it in ignoramus; and if the bill be found, the prisoner is brought to the bar of the court, and the clerk of the arraignment calling him by his name, desires him to hold up his hand, saying, "Thou art indicted by the name of — —, for such a felony, &c. setting forth the crime laid in the indictment. How sayest thou, art thou guilty of this felony whereof thou art indicted, or not guilty?" To which the prisoner answering, "Not guilty," the clerk says, "Culprit, how wilt thou be tried?" whereupon the defendant answers, "By God and my country;" which plea of the prisoner the clerk records, and then the pannel of the petty-jury is called over.

After the jury are sworn, and the indictment is read over to them, and they are charged, the evidences on both sides, for and against the prisoner, are called, sworn, and examined in open court; after which the jury bring in their verdict; and if they find the prisoner guilty, their verdict is recorded, and the prisoner is taken from the bar: but if they bring him in not guilty, the prisoner is bid to fall down on his knees, &c. On the prisoner's being brought in guilty, proclamation is made for all persons to keep silence, upon which the prisoner is again brought to the bar, and the verdict repeated: after which sentence is passed on him, and an order or warrant is made for his execution.

The methods of trial, in our civil courts, are as follows: viz. The declaration is first drawn for the plaintiff, and when the appearance of the defendant is entered, it has been usual to deliver it with an imparlance to the defendant's attorney; and the term following rule is to be given with the secondary for the defendant to plead by such a day, or else the plaintiff is to have judgment: and the defendant having pleaded, a copy of the issue is made by the plaintiff, and delivered to the defendant's attorney, at the same time giving him notice of the trial; in order to which the *venire facias* must be taken out and returned by the sheriff; and likewise the *habeas corpora*, or *distingas*, to bring in the jury; on which the record is made up, and the parties proceed to trial by their council and witnesses, and the jury give in their verdict, &c. But in case the defendant neglects to plead, and suffers it to go by default, on entering such a judgment, a writ of inquiry of damages is awarded returnable next term; notice of the execution whereof the defendant's attorney is to have, and which being executed, and the damages inserted in a schedule annexed to the writ, a rule is given thereon, and costs are taxed by the prothonotary, &c.

TRIANGLE, in geometry, is a figure of three sides and three angles, and is either plane or spherical.

Plane TRIANGLE, is that contained under three right lines.

Spherical TRIANGLE, is that contained under three arches of a great circle of the sphere.

Of *Plane Triangles* there are several sorts, as,

1. A *Right-Angled TRIANGLE*, is that which hath one right angle.
2. An obtuse-angled triangle, is such as hath one obtuse angle.
3. An acute-angled triangle, is that which hath all its angles acute.
4. Any triangle that is not right-angled, is called oblique-angled.
5. An equilateral triangle, is that which hath all its sides equal to one another.
6. An isosceles triangle, is that which hath only two sides equal.
7. A scalenous triangle, is that which hath no two sides equal.

In every triangle the sum of all the three angles is equal to two right ones, and the external angle, made

by any side produced, is equal to the two internal opposite angles taken together.

In every triangle, as well plane as spherical, the sines of the sides are proportional to the sines of the opposite angles.

The side of an equilateral triangle, inscribed in a circle, is, in power, triple of the radius.

In every right-angled triangle, the square of the hypotenuse is equal to the sum of the squares of the other two sides.

Triangles on the same base, and having the same height, that is, between the same parallel lines, are equal.

Every triangle is one half of a parallelogram of the same base and height.

The area of any right-lined triangle may be had, by multiplying the base by half the perpendicular height, or the perpendicular height by half the base.

The area of any plane triangle may be had by adding all the three sides together, and taking half the sum, and from that half sum subtracting each side severally, and multiplying that half sum and the remainder continually into one another, and extracting the square root of the product.—For the solving the several cases of plane and spherical triangles, see **TRIGONOMETRY**.

TRIANGULAR Compasses, are such as have three legs, or feet, whereby to take off any triangle at once; much used in the construction of maps, globes, &c.

TRIANGULAR Numbers, are a kind of polygonal numbers, being the sums of arithmetical progressions, the difference of whose terms is 1.

Thus of arithmetical progression, 1 2 3 4 5 6, are formed triangular numbers 1 3 6 10 15 21.

TRIANGULAR Canon, the tables of artificial sines, tangents, secants, &c.

TRIANGULAR Quadrant, is a sector furnished with a loose piece, whereby to make it an equilateral triangle.

The calendar is graduated thereon, with the sun's place, declination, and other useful lines; and by the help of a spring and a plummet, and the divisions graduated on the loose piece, it may be made to serve for a quadrant.

TRIANGULARIS, in anatomy, a name given to two muscles in respect of their figure.

The *triangularis pectus*, which has sometimes the appearance of three or four distinct muscles, arises from the inside of the sternum, and is implanted into the cartilages, which join the four lowest true ribs to the sternum.

The action of this muscle is very obscure, since both the organization and insertion are at parts not moveable, but together.—Dr. Drake conjectures it may conduce towards forming the necessary incurvation of the sternum, and by its over-tension in children, while the cartilages are soft, may occasion that morbid acumination in the sternum seen in rickety children.—Others suppose it may contract the cavity of the thorax in expiration.

TRIARI, in the Roman militia, a kind of infantry armed with a pike, a shield, a helmet, and a cuirass; thus called because they made the third line of battle.

TRIAS HARMONICA, or the *harmonical TRIAD*, in music, a compound of three radical sounds, heard all together, two whereof are a fifth and third above the other, which is a fundamental.

TRIBE, *Tribus*, in antiquity, a certain quantity or number of persons, when a division is made of a city or people into quarters or districts.

The tribes of ancient Rome bore a great resemblance to our wards.

TRIBRACHYS, in ancient poetry, a foot consisting of three syllables, and those all short; as *melius*.

TRIBULUS, caltrop, in botany, a genus of plants, the corolla of which consists of five oblong, obtuse, and patent petals: its fruit is of a roundish figure and aculeated, being composed of five capsules, gibbous on one side, and armed with three or four points on the other, angulated and convergent; and containing numerous seeds, turbinate and oblong.

There are three species of this plant enumerated by Mr. Miller; the first of which is very common in the south of France, in Spain, and Italy, where it grows among corn, and on most of the arable land, and is very troublesome to the feet of cattle; for the fruit being armed

armed with strong prickles, run into the feet of cattle, which walk over the land. This is certainly the plant which is mentioned in Virgil's *Georgics*, under the name of *tribulus*, though most of his commentators have applied it to other plants.

It is called in English *caltrop*, from the form of the fruit, which resembles those instruments of war that were cast in the enemies way to annoy their horses.

This hath a slender fibrous root, from which spring out four or five slender hairy stalks, which spread flat on the ground, garnished at each joint with winged leaves, composed of six pair of narrow hairy lobes, almost of equal size; those on the lower part of the stalk stand alternately, but toward the top they are placed opposite. The flowers come out from the wings of the stalk, standing upon short foot-stalks; they are composed of five broad, obtuse, yellow petals, which spread open. In the center is situated an oblong germen, crowned by a headed stigma, attended by ten short stamina, terminated by single summits, and are succeeded by roundish, five-cornered, prickly fruit, which, when ripe, divides into five parts, each having a transverse cell, containing one or two seeds.

This plant is preserved in botanic gardens for variety. It is propagated by seeds, which should be sown in autumn; for those which are kept out of the ground till spring, commonly remain in the ground a whole year before the plants come up. These seeds should be sown on an open bed of light earth, where they are designed to remain; for, as it is an annual plant, it doth not bear transplanting very well, unless it be done when the plants are very young. In the spring when the plants come up, they should be carefully cleared from weeds; and where they come up too close, some of the plants should be pulled out to give room for the remaining plants to grow; after this they will require no other culture but to keep them clear from weeds. If the seeds are permitted to scatter, the plants will come up the following spring, and maintain their place, if they are not overborne with weeds.

The second sort grows naturally in Jamaica, and some of the other islands in the West-Indies; this is an annual plant, with pretty thick, compressed, channelled stalks, which trail upon the ground, garnished with smooth winged leaves, placed by pairs opposite; they are sometimes composed of three, but most commonly of four pair of lobes, the outer being the largest. The flowers come out from the wings of the stalk; they are composed of five large yellow petals, which spread open, and have an agreeable odour; these are succeeded by roundish prickly fruit, ending in a long point, but seldom ripen in England.

The third sort grows naturally in the West-Indies; it was found by the late Dr. Houstoun at the Havanna; this has a ligneous root, from which spring out many stalks, which are hairy, jointed, and trail upon the ground, garnished at each joint by winged leaves, which differ greatly in size, some being composed of eight pair of oblong lobes which are nearly equal, but opposite to these come out small leaves composed of but four pair of lobes. The large leaves stand alternately upon the stalks, and the small ones on the opposite side; at the wings of the stalks come out the foot stalks of the flowers, which are hairy, and near two inches long, each sustaining one pale yellow flower, composed of five large petals, which have narrow tails, but are very broad and rounded at their points. The flowers are succeeded by roundish fruit armed with very acute spines, but these rarely ripen in England.

The two last sorts being natives of hot countries, are very tender, so must be sown in pots in autumn, and plunged into the tan-bed in the stove: when the plants are come up, they must each be transplanted into a separate pot, and then plunged into a hot-bed of tanners bark, where they must be treated in the same manner as other tender exotic plants, being careful to bring them forward as early as possible in the summer, otherwise they will not perfect their seeds in this country.

The third sort will live through the winter, if it is plunged in the bark-stove, and treated in the same man-

ner as other tender plants, and the following summer they will flower earlier, so there will be more time for the seeds to ripen.

TRIBUNAL, in general denotes the seat of a judge, called in our courts bench.

The word is Latin, and takes its origin from the seat where the tribune of the Roman people was placed to administer justice.

The name tribunal was also given to the place from whence the people of antient Rome were harangued.

TRIBUNE, *Tribunus Plebis*, among the antient Romans, a magistrate chosen out of the commons, to protect them against the oppressions of the great, and to defend the liberty of the people against the attempts of the senate and consuls.

The tribunes of the people were first established in the year of Rome 259. The first design of the creation was to shelter the people from the cruelty of usurers, and to engage them to quit the Aventine mount, whither they had retired in displeasure.

Their number, at first, was but two; but the next year, under the consulate of A. Posthumus Aruncius and Cassius Viscellinus, there were three more added; and this number of five was afterwards increased, by L. Trebonius, to ten. The appellation, tribune, was given them, by reason they were at first chosen out of the tribunes of the army.

Military TRIBUNE, *Tribunus Militum*, or *Militaris*, an officer in the Roman army who commanded in chief over a body of forces, particularly the division of a legion, much the same with our colonel, or the French mester de camp.

TRIBUNE was also an appellation given to various other officers; as the *tribuni ærarii*, tribunes of the treasury. Tribune of the celeres, the officer who commanded them. *Tribuni fabricarum*, those who had the direction of the making of arms. *Tribuni marinorum*, *tribuni nolanorum*, *tribuni voluptatum*, mentioned in the Theodosian Code, as intendants of the public shews, and other diversions. The title of tribune, *tribunus*, was also given to the chief of each tribe.

TRIBUTARY, *Tributarius*, one who pays tribute to another, in order to live in peace with him, or share in his protection.

TRIBUTE, *Tributum*, a tax or impost which one prince or state is obliged to pay to another, as a token of dependence, or in virtue of a treaty, and as a purchase of peace.

The Romans made all the nations they subdued pay them tribute. Mahomet laid it down as a fundamental of all his law, that all the world should pay him tribute. In the states of the grand seignior Christian children are taken by way of tribute. See **AGEMOGLANS**.

Tribute is sometimes also used for a personal contribution, which princes lay upon their subjects, by way of poll money.

TRICEPS, in anatomy, the abductor muscle of the thigh, having three heads and as many insertions: the first and second heads of this muscle arise from the os pubis, near the synchondrosis; the third, from the tubercle of the ischium; and it is inserted into the whole spine of the os femoris.

TRICHERIÆ, a genus of fossils, naturally and essentially simple, not inflammable nor soluble in water; being fibrose bodies, not elastic, and composed of straight and continuous filaments.

To this genus belongs the *gypsum striatum* of authors, with several other species.

TRICHESTRUM, in natural history, the name of a genus of fossils, of the class of the selenitæ, but differing extremely in figure and structure from the common kinds.

The selenitæ of this genus are composed of filaments scarce any where visibly arranged into plates or scales, but disposed in form of a radiated star, made of a number of disjunct striæ.

TRICHIASIS, in surgery, an inversion of the eyelids, whereby the eye-lashes hurt the eyes.

According to Heister, this disorder is very difficultly remedied; since it is hardly possible to remove it, so as to

prevent its returning, without extirpating the offending hairs; and if these be cut off close, it will be to no purpose, because the rigid stumps of the hairs will irritate the eye even worse than the whole hairs did before. It is a very nice operation alone that can make a cure; here the hairs must be pulled up singly by the roots, and the places of their insertion singly cauterized with a hot broad pointed needle; but this the patient will seldom submit to, and the only remaining method then, is to fill up the sinus's out of which they were extracted with the lapis infernalis. But in this the greatest care must be taken, that no part of that application get into the eye. The easiest method is the touching the cavities, out of which the hairs have been pulled up, with a pencil-brush dipped in a mixture of spirit of sal-armoniack and highly rectified spirit of wine, by which means they will close up, and no more hairs will grow from them.

TRICHILIA, in botany, a genus of plants, whose flower consists of five lanceolated patent petals, with a cylindric tubulose nectarium, cut at the mouth into five indentures; the stamina have no filaments, but consist of ten erect assurgent antheræ: the fruit is a roundish almost trigonal capsule, having three cells, each containing a single seed.

TRICHOMANES, in botany, a genus of plants of the fern kind; the visible parts of the fructification consists of a turbinated erect calyx standing singly on the very margin of the leaf, and a setaceous style terminating the capsule.

TRICHOSANTHES, in botany, a genus of plants, whose flowers are male and female, and grow on the same plant; the male flower is monopetalous, and divided into five segments, and contains three very short filaments, topped with cylindrical erect antheræ, joined in a body; the female flower is like the male, and the fruit is long, succulent, and trilocular, containing many obtuse compressed seeds. This genus comprehends the anguina of Micheli.

TRICHOSTEMA, in botany, a genus of plants, whose flower is monopetalous and ringent; the tube is very short; the upper lip is compressed and falcated, and the under one is divided into three parts, the middle one being oblong and smallest: the stamina are four very long filaments, topped with single antheræ; there is no pericarpium, but the cup contains four roundish seeds.

TRICUSPIDES, **VALVÆ**, in anatomy, a name given to the mitral valves, placed at the juncture of the right auricle and ventricle of the heart.

TRIDAX, American starwort, in botany, a genus of plants, whose flowers are compound and radiated, consisting of hermaphrodite florets, which form the disc, and ligulated female corollulæ, which compose the rays; the cup, which is cylindrical and imbricated, contains the seeds, which are oblong and crowned with down.

TRIDENT, *Tridens*, an attribute of Neptune, being a kind of sceptre which the painters and poets put into the hands of that god, in form of a spear, or fork, with three teeth; whence the word.

TRIDENT, among mathematicians, is used for a kind of parabola, by which Des Cartes constructed equations of six dimensions.

TRIEDROSTYLA, in natural history, the name of a genus of spars, in form of trigonal columns, adhering by one end to some solid body, and terminated at the other by a trigonal pyramid. See **SPAR**.

Of this genus there are four known species. 1. A slender one, with a long, obtuse pyramid: this is one of the most common of all the spars, and is found in almost all parts of the world, sometimes in single and large specimens, but more frequently in large congeries, coating over the fissures of stone, in form of crusts. 2. One with short, but pointed pyramids, common on Mendip-hills, and found in some other parts of England. 3. A thick one, with a longer pyramid, found in Northamptonshire, and some other parts of the kingdom, encrusting the fissures of stone. And, 4. One with a very short column, and a long, obtuse pyramid: this is frequent in the mines of Germany, and not less so in those of England, particularly in Derbyshire.

TRIEMIMERES, a kind of cæsura in Latin verse, wherein after the first foot of the verse there remains an odd syllable, which helps to make up the next foot.

TRIENNIAL, an epithet applied chiefly to offices or employments which last for three years.

TRIENS, in antiquity, a copper money of the value of one third of an as, which on one side bore a Janus's head, and on the other a water-rat.

This was the piece of money used to be put in the mouths of the deceased to pay Charon his fare, for their passage into another life.

TRIENTALIS, in botany, a genus of plants, whose flower is stellated and monopetalous, with the corolla divided into seven ovato-lanceolated segments; the stamina consists of seven capillary filaments, inserted into the unguis of the corolla, and topped with single antheræ.

TRIEXAHÆDRIA, in natural history, the name of a genus of perfect and pellucid, crystalliform spars, consisting of thrice six planes, being composed of an hexangular column, terminated at each end by an hexangular pyramid. Of this genus there are three known species. 1. A clear one, with narrow and oblong pyramids: this is found in the mountains of Germany and in North Wales; but with us it is small and coarse. 2. One with short pyramids, and a long column: this is found in the mines at Gosselaer, in Saxony. And, 3. One with short pyramids, and a thick and short column, found with us in the lead-mines of Yorkshire.

TRIGA, in antiquity, denotes a kind of carr, or chariot, drawn by three horses; whence the name.

TRIGAMY, a third marriage, or the state of a person who has been married three times.

TRIGLA, in ichthyology, a genus of fishes, the characters of which, according to Artedi, are these: the branchiostegæ membrane contains several bones; the head is very declivious, from the eyes to the end of the snout, and is large, aculeated, and as it were square; the head is the broadest part of the fish; it thence grows gradually narrower, till it ends in a very small tail; in many of the species of this fish, there are two or three articulated appendices growing under the pectoral fins: the eyes stand on the top of the head, and are covered with a skin; there are two back fins, the first of which is prickly; the pectoral fins in some of the species are very large.

TRIGLYPHS, in architecture, a sort of ornaments repeated at equal intervals in the Doric freeze.

Each triglyph consists of two entire gutters, or channels, cut to a right angle, called glyphes, and separated by three interstices, called, by Vitruvius, femora, from each other, as well as from two other half channels which are at the sides.

The ordinary proportion of triglyphs is to be a module broad, and one and a half high. But this proportion, M. le Clerc observes, sometimes occasions ill-proportioned intercolumniations in porticos; for which reason he chooses to accommodate the proportion of his triglyphs to that of the intercolumns.

TRIGON, *τριγων*, a triangle. See **TRIANGLE**.

In astrology, trigon denotes the same with trine. See **TRINE**.

TRIGONELLA, fenugreek, in botany. See the article **FENUGREEK**.

TRIGONOMETRY, the art whereby, from any three parts of a triangle, except the three angles, (when the triangle is a plane one) the rest are discovered.

The word is formed from the Greek *τριγωνος*, a triangle, and *μετροω*, to measure.

Trigonometry is either plane or spherical.

Plane TRIGONOMETRY, is the method of solving plane triangles.

Solution of the several cases of plane TRIGONOMETRY.

Case I. The angles and one of the legs of a right-angled plane triangle being given, to find the other leg.

Example. In the triangle ABC (plate CXXXII. fig. 1.) right-angled at B,

Are given AB = 52 equal parts, as yards, furlongs, miles, &c.

And the angle C A B = 36 deg. 52 min. required B C.

The geometrical solution.—1. Make AB equal to 52, by a line of equal parts.

2. Extend your compasses to the distance of the radius of your line of chords, and with this distance, setting one foot in A, describe the arch *ef*, and from *f* towards *e* set off 36 deg. 52 min. the angle at A, on the arch *fe*.

3. Erect the perpendicular BC.

4. From A, through the intersection *e*, draw the line AC, meeting the perpendicular BC in C; then is the triangle constructed, and the perpendicular BC may be measured, by applying it to the same line of equal parts from whence AB was taken.

The arithmetical solution. 1. By supposing AC the radius.

Produce AC (plate CXXXII. *fig. 1.*) to *c*, till *Ac* be equal to the tabular radius 10000000, &c. then will *bc* be the tabular sine of the arch *cd*, and *Ab* will be the tabular co-sine of the same arch: also, BC will be the sine of the arch BD, and AB the co-sine of the same arch.

And because the triangles ABC, *Abc*, are similar, it will be,

As *Ab*:AB::*bc*:BC. That is,

$$\begin{array}{l} \text{As } Ab \text{ (the tabular co-sine of the arch } cd) = 36^\circ 52' \\ \text{52' = } \frac{52}{10000000} \\ \text{To AB (the co-sine of the arch CD in the} \\ \text{scheme) = 52 = } \frac{52}{10000000} \\ \text{So is } bc \text{ (the tabular sine of the arch } cd) = 36^\circ 52' \\ \text{52' = } \frac{52}{10000000} \end{array} \left\{ \begin{array}{l} 9,9031084 \\ 1,7160033 \\ 9,7781186 \end{array} \right.$$

$$\text{To CB (the sine of the arch CD in the scheme) } \left\{ \begin{array}{l} \text{required} = 39 = \frac{39}{10000000} \\ 1,5910135 \end{array} \right.$$

2. By supposing AB (*fig. 2.*) the radius.

Produce AB to *b*, till *Ab* be equal to the tabular radius, then will *bc* be the tabular tangent of the arch *bd*, and BC the tangent of the arch BD.

And because the triangles ABC, *Abc*, are similar, it will be,

As *Ab*:AB::*bc*:BC. That is,

$$\begin{array}{l} \text{As } Ab \text{ (the radius in the tables) = } 90^\circ = \frac{90}{10000000} \\ \text{To AB (the radius of the scheme) = 52 = } \frac{52}{10000000} \\ \text{So is } bc \text{ (the tangent of the arch } bd \text{ in the ta-} \\ \text{bles) = } 36^\circ 52' = \frac{52}{10000000} \end{array} \left\{ \begin{array}{l} 10,0000000 \\ 1,7160033 \\ 9,8750102 \end{array} \right.$$

$$\text{To BC (the tangent of the arch BD in the} \\ \text{scheme) = 39 = } \frac{39}{10000000} \left\{ \begin{array}{l} 1,5910135 \end{array} \right.$$

3. By supposing BC (*fig. 3.*) the radius.

Produce CB to *b*, till *Cb* be equal to the tabular radius, then will *ab* be the tabular tangent of the arch *bd*, or angle *aCb*, the complement of the given angle; also, AB will be the tangent of the arch BD.

And because the triangles *Cab*, CAB, are similar, it will be,

As *ab*:AB::*Cb*:CB. That is,

$$\begin{array}{l} \text{As } ab \text{ (the tabular tangent of the arch } bd \\ \text{53}^\circ 8' \text{) = } \frac{52}{10000000} \\ \text{To AB (the tangent of the arch BD in the} \\ \text{scheme) 52, = } \frac{52}{10000000} \\ \text{So is } Cb \text{ (the tabular radius) = } 90^\circ = \frac{90}{10000000} \end{array} \left\{ \begin{array}{l} 10,1249898 \\ 1,7160033 \\ 10,0000000 \end{array} \right.$$

$$\text{To CB (the radius of the scheme) = 39 = } \frac{39}{10000000} \left\{ \begin{array}{l} 1,5910135 \end{array} \right.$$

Case II. The angles and one of the sides of a right-angled plane triangle being given, to find the hypotenuse.

Example. In the triangle ABC (*fig. 1.*) right-angled at B, are given the angle CAB = 36 deg. 52 min. and the side AB = 52 equal parts; required the hypotenuse AC.

Geometrically. This case is constructed, in all respects, like the former, and AC may be measured by the same line of equal parts which AB was taken from.

Arithmetically. 1. By supposing AC (*fig. 1.*) the radius.

Produce AC to *c*, till *Ac* be equal to the tabular radius, then will *bc* be the sine of the arch *cd*, and CB the sine of the arch CD; also, *Ab* will become the co-sine of the arch *cd*; or, which is all one, the sine of

its complement, and AB the co-sine of the arch CD, or sine of its complement.

And because the triangles ABC, *Abc*, are similar, it will be,

As *Ab*:AB::*Ac*:AC. That is,

$$\begin{array}{l} \text{As } Ab \text{ (the tabular co-sine of the arch } cd) \\ \text{36}^\circ 52' \text{ = } \frac{52}{10000000} \\ \text{Is to AB (the co-sine of the arch CD in} \\ \text{the scheme) = 52 = } \frac{52}{10000000} \\ \text{So is } Ac \text{ (the tabular radius) = } 90^\circ = \frac{90}{10000000} \end{array} \left\{ \begin{array}{l} 9,9031084 \\ 1,7160033 \\ 10,0000000 \end{array} \right.$$

$$\text{To AC (the radius in the scheme) = 65 = } \frac{65}{10000000} \left\{ \begin{array}{l} 1,8128949 \end{array} \right.$$

2. By supposing AB the radius.

Produce AB (*fig. 2.*) to *b*, till *Ab* be equal to the tabular radius, then will *bc* be the tangent of the arch *bd*, and *Ac* the secant of the same arch; also, BC will be the tangent of the arch BD, and AC the secant of the same.

And, because the triangles ABC, *Abc*, are similar, it will be,

As *Ab*:AB::*Ac*:AC. That is,

$$\begin{array}{l} \text{As } Ab \text{ (the radius in the tables) = } 90^\circ = \frac{90}{10000000} \\ \text{Is to AB (the radius in the scheme) = 52 = } \frac{52}{10000000} \\ \text{So is } Ac \text{ (the secant of the arch } bd \text{ in the} \\ \text{tables) = } 36^\circ 52' = \frac{52}{10000000} \end{array} \left\{ \begin{array}{l} 10,0000000 \\ 1,7160033 \\ 10,0968916 \end{array} \right.$$

$$\text{To AC (the secant of the arch BD in the} \\ \text{scheme) 65, = } \frac{65}{10000000} \left\{ \begin{array}{l} 1,8128949 \end{array} \right.$$

3. By supposing BC (*fig. 3.*) the radius.

Produce CB to *b*, till *Cb* be equal to the tabular radius, then will *ab* be the tabular tangent of the arch *bd* (or angle *aCb*) and *Ca* will be the secant of the same arch; also, AB will be the tangent of the arch BD, and CA the secant of the same arch.

And because the triangles *abC*, ABC, are similar, it will be,

As *ab*:AB::*Ca*:CA. That is,

$$\begin{array}{l} \text{As } ab \text{ (the tabular tangent of the arch } bd) \\ \text{53}^\circ 8' \text{ = } \frac{52}{10000000} \\ \text{Is to AB (the tangent of the arch BD in the} \\ \text{scheme) 52, = } \frac{52}{10000000} \\ \text{So is } Ca \text{ (the tabular secant of the arch} \\ \text{bd) 53}^\circ 8' \text{ = } \frac{52}{10000000} \end{array} \left\{ \begin{array}{l} 10,1249898 \\ 1,7160033 \\ 10,2218814 \end{array} \right.$$

$$\text{To CA (the secant of the arch BD in the} \\ \text{scheme) 65, = } \frac{65}{10000000} \left\{ \begin{array}{l} 1,8128949 \end{array} \right.$$

By carefully considering the three different methods of performing the two preceding cases, the reader may make these three general observations:

1. If the hypotenuse be supposed the radius, the two legs will become the sines of their opposite angles.

2. If the base be supposed the radius, the perpendicular will become the tangent of the angle at the base, and the hypotenuse the secant of the same angle.

3. If the perpendicular be supposed the radius, the base will become the tangent of the angle at the perpendicular, and the hypotenuse the secant of the same angle.

Case III. The hypotenuse and angles of a right-angled plane triangle being given, to find either of the legs.

Example. In the triangle ABC (*fig. 1.*) right-angled at B, are given the angle CAB = 36 deg. 52 min. and the hypotenuse AC = 65, required AB.

Geometrically. 1. Draw the line AB at pleasure.

2. Make the angle at A equal to 36 deg. 52 min. by the line of chords (as taught in the first case) and continue the line AC, till it be equal to 65, upon the line of equal parts.

3. Let fall the perpendicular CB, and the triangle is constructed; and the base AB may be measured by applying it to the same line of equal parts which AC was taken from.

Arithmetically. By supposing AC (*fig. 1.*) the radius.

Produce AC to *c*, till it equal the tabular radius, then will *Ab* = the tabular co-sine of the angle at A, or the sine of the angle *Ac b*, it being its complement.

And from the similarity of the two triangles *Abc*, ABC, it will be,

As

T R I

6

2. Make $AB = 52$, by a line of equal parts.
3. Make the angle $B = 104^{\circ} 43'$ by the line of chords.
4. Draw the lines AC and BC till they intersect each other in C , and the triangle ABC is constructed; and AC may be measured by the same line of equal parts which AB was taken from.

Arithmetically. As the sine of the angle $C = 42^{\circ} 16'$ $\left. \begin{array}{l} \text{To its opposite side } AB \\ \text{So is the sine of the angle } B = 104^{\circ} 43' \end{array} \right\} \begin{array}{l} 9,8291312 \\ 1,7160033 \end{array}$

To its opposite side $AC = 74,5 = 1,8723856$

Case III. Two sides and an angle opposite to one of them being given, to find the other side.

Example. In the oblique-angled plane triangle ABC (*fig. 4.*) are given the side $AB = 52$, the side $BC = 42$, and the angle $C = 42^{\circ} 16'$ required AC .

Geometrically. This case is constructed in all respects like the first, and the side AC may be measured by applying it to the line of equal parts.

But to perform it arithmetically, it will be,
As the side $AB = 52 = 1,7160033$
Is to the sine of the angle $C = 42^{\circ} 16' = 9,8291312$
So is the side $BC = 42 = 1,6232493$

To the sine of the angle $A = 33^{\circ} 1' = 9,7363772$

Hence the angle $B = 104^{\circ} 43'$.

Then to find the side AC it will be, by the same theorem,

As the sine of the angle $C = 42^{\circ} 16' = 9,8291312$
Is to the side $AB = 52 = 1,7160033$
So is the sine of the angle $B = 104^{\circ} 43' = 9,9855135$

To the side $AC = 74,5 = 1,8723856$

Case IV. Two sides and the contained angle of an oblique-angled plane triangle being given, to find the other angles.

Example. In the oblique-angled plane triangle ABC (*fig. 3.* plate CXXXII.) are given the side $AC = 74,5$, the side $AB = 52$, and angle $A = 33^{\circ} 1'$ required the angles B and C .

Geometrically. 1. Make the line $AC = 74,5$ by a line of equal parts.

2. Form the angle $A = 33^{\circ} 1'$ by the line of chords.

3. Let AB be made $= 52$ equal parts.

4. Join the points B and C with a right-line, and the thing is done; and the angles B and C may be measured by the line of chords.

To perform this case arithmetically, we must first find the sum and difference of the two sides; also the half sum of the two unknown angles, which is performed by subtracting the given angle from 180° , and the remainder will be the sum of the angles B and C , the half of which will be the half sum required, which will be $= 73^{\circ} 29' 30''$.

Having found the sum and difference of the two sides, as, also, the half sum of the two unknown angles, the required angles will be found thus,

As the sum of the two sides AB and $AC = 126,5 = 2,1000905$
To their difference $= 22,5 = 1,3533825$
So is the tangent of the half sum of the two unknown angles $= 73^{\circ} 29' 30'' = 10,5293633$

To the tang. of half their difference $= 31^{\circ} 13' 30'' = 9,7826553$

To the half sum $= 73^{\circ} 29' 30''$
Add the half difference $= 31^{\circ} 13' 30''$

Their sum will be the greater ang. $B = 104^{\circ} 43' 00''$
From the half sum $= 73^{\circ} 29' 30''$
Take the half difference $= 31^{\circ} 13' 30''$

Their difference $=$ the angle $C = 42^{\circ} 16'$

Case V. Two sides and the contained angle of any oblique angled plane triangle being given, to find the third side.

Example. In the oblique-angled plane triangle ABC (*fig. 3.*) are given the side $AC = 74,5$, the side $AB = 52$, and the angle $A = 33^{\circ} 1'$ required the side BC .

Geometrically. The geometrical construction of this case is exactly the same with the last, and the side BC may be measured by the line of equal parts.

This case is compounded of the fourth and first, and therefore the arithmetical method is the same as those two cases; for the angles B and C must be found by case the fourth, and the side BC will be found by case the first, to which we refer the reader.

Case VI. Three sides being given, to find the angles.

Example. In the oblique-angled plane triangle ABC (*fig. 3.*) are given the side $AB = 52$, the side $AC = 74,5$, and the side $BC = 42$, required the angles A , B , and C .

Geometrically. 1. Make the line $AC = 74,5$, from a line of equal parts.

2. Take 52 , the length of AB between the points of the compasses, and, setting one foot in A , with the other describe the arch de .

3. Take 42 , the length of BC , between the points of the compasses, and, setting one foot in C , with the other describe the arch fg , intersecting the former in B .

4. From the intersection B draw right-lines to the points A and C , and the triangle is constructed; and the angles may be measured by the line of chords.

But to perform it arithmetically, it will be,

As the base AC (pl. CXXXII. *fig. 5.*) $= 74,5 = 1,8721563$
To the sum of the sides $AB, BC = 94 = 1,9731279$
So is the difference of the sides $AB, BC = 10 = 1,0000000$

To the difference of the segments $AF, CF, \left. \begin{array}{l} 12,5 \\ 12,5 \end{array} \right\} 1,100971$

Which, taken from $AC = 74,5$, leaves twice $CF = 62$, the half of which is $31 =$ the lesser segment FC . Then having the three sides of a right-angled triangle, the angles are easily found.

We shall here subjoin the following curious and useful theorems, for facilitating the operations in plane trigonometry.

Theorem 1. The sine of the sum of any two arches, is equal to the sum of the products of each sine multiplied into the co-sine of the other's arch divided by the radius.

Demonstration. Let AB and AC , (*fig. 6.*) be the double of the given arches, then will BC be the chord of their sum. Draw the diameter AD , join the points B, D and D, C , let fall AO , perpendicular upon BC . The triangles AOC, ABD , are similar, as are also the triangles AOB, ACD ; whence we get $AB : BO :: AD : CD$, and $AC : CO :: AD : BD$, therefore $BO + CO (BC)$ is equal to $\frac{AB \times CD + AC \times BD}{AD}$;

or by dividing all by 2, we get $\frac{BC}{2} = \frac{\frac{1}{2} AB \times \frac{1}{2} CD}{\frac{1}{2} AD} + \frac{\frac{1}{2} AC \times \frac{1}{2} BD}{\frac{1}{2} AD}$.

Corol. 1. As radius is to the sine of an arch, so is twice its co-sine, to the sine of double that arch.

Corol. 2. The sine of the difference of any two arches is equal to the difference of the products of the sine of one arch into the co-sine of the other, divided by the radius.

Theorem 2. As radius is to the sine of half the sum of two arches, so is the sine of half their difference, to half the difference of the versed sines of the same two arches.

Demonstration. Let AC (*fig. 7.*) be the greater arch, and CD the less. Make $AB = CD$, then $BC = AC - CD$; draw the chord BC , which bisect in E with the radius FEH . Let fall Hd, Cc , and Ba , perpendiculars to AF , then will Hd be the sine of $\frac{1}{2}$ the sum, and BE the sine of $\frac{1}{2}$ the difference of the given arches, and $ab = bc$ will be $\frac{1}{2}$ the difference of their versed sines.

The triangles FHd , ECK are similar, whence $FH : Hd :: EC : EK$ (*ab*).

Theorem 3. The sum of the tangents of any two arches is to their difference, as the sine of the sum of those arches, is to the sine of their difference.

Demonstration. Let AH (*fig. 8.*) be the greater arch, $HG (=HI)$ the less; join the points I, G , produce GI to L , draw the tangents HM, HF ; upon ME let fall the perpendiculars IK, GD , then will GD be the sine of the sum of the given arches, and IK that of their difference. The triangles LGD, LIK are similar, whence $GD : KI :: LG : LI$. The triangles MCF, LCG are similar, whence we have $MF : MP :: LG : LI$, and therefore $GD : KI :: MF : MP$.

Corol. The sine of an arch is a mean proportional between half the radius and the versed sine of twice that arch: for by letting fall Ib perpendicular upon CG , the triangles ISC, IbG become similar; whence $IS : IC :: Gb : 2IS$, and therefore $IS^2 = \frac{1}{2} \times Gb$.

Theorem 4. The double of the rectangle contained under the co-sines of two arches divided by the radius, is equal to the sum of the co-sines of the sum and difference of those arches.

Demonstration. Let AB and BD (*fig. 9.*) equal to BE , be the two arches, and CG and Cn their respective co-sines to the radius CB ; likewise let CH be the co-sine of their sum AE , and CF that of their difference AD ; making nm parallel to BG . Then, Dn being $=En$, it follows that $Fm = Hm$; and consequently that $2Cm = CH + CF$: but, by similar triangles, $CB : CG :: Cn : Cm$; whence $CG \times 2Cn = CB \times CH + CF$, and consequently $\frac{CG \times 2Cn}{CB} = CH + CF$.

Corol. 1. The double of the rectangles contained under the sines of any two arches divided by the radius, is equal to the difference of the co-sines of the sum and difference of those arches.

Corol. 2. The double of the rectangle under the co-sine of the one and the sine of the other, is equal to the difference of the sines of the sum and the difference of the said arches.

Theorem 5. The rectangle of the sines of any two arches being added to that of their co-sines, is equal to the rectangle of the radius and cosine of the difference of those arches.

Demonstration. Let HE (*fig. 10.*) be the greater of the given arches, and DE the less, then will HD be their difference. Draw the radii CD, CE , and the right sines DB, EA , and DF ; draw also OP , from the point of intersection O parallel to DF : then will $CE \times PE = AE \times OE$: *Euc. 37.3.* but $CF : PC :: CB : AC$, by the similar triangles CFD, CPO ; and again, $BC : CE :: FD : OE$; hence we get $CF \times AC = PC \times CB$, and $BC \times OE = CD \times FD$; consequently $PE \times BC = AE \times FD$; that is, $PE \times BC + AC \times FC = AE \times FD + AC \times FC = PE \times BC + PC \times BC = PE + PC \times BC = CD \times BC$.

Spherical TRIGONOMETRY, is the art whereby, from three given parts of a spherical triangle, the rest are discovered.

Before we shew the method of solving the several cases of spherical trigonometry, we shall lay down and demonstrate the following theorems.

Theorem 1. In any right-angled spherical triangle it will be, as radius is to the sine of the angle at the base, so is the sine of the hypotenuse to the sine of the perpendicular; and, as radius to the co-sine of the angle at the base, so is the tangent of the hypotenuse to the tangent of the base.

Demonst. Imagine the quadrants $CQED, CLFD$ (*fig. 11.*) raised up until they meet in D , and then place the plane CEF perpendicular to the plane $CQED$, and suppose the point F of the plane CEF to coincide with the point F of the plane $CLFD$: By these means there will be formed a right-angled spherical triangle DEF right-angled at E ; then in this triangle it will be, as the radius CF , is to LP , the sine of the angle EDF at the base, so is RF , the sine of the hypotenuse DF , to FK , the sine of the perpendicular EF . For the plane FCE is perpendicular to the plane CDE ; there-

fore the right-lined triangle KRF is similar to CLP ; whence $CL : LP :: RF : KF$. But $CL = CF$, whence $CF : LP :: RF : KF$. Again, as CL the radius is to CP the co-sine of the angle EDF at the base; so is CH , the tangent of the hypotenuse DF , to SC , the tangent of the base DE . For the right-lined triangles CHS, CLP are similar, wherefore $CL : CP :: CH : CS$.

Corol. 1. Hence it follows, that the sines of the angles of any oblique spherical triangle are to one another directly, as the sines of the opposite sides.

Corol. 2. It follows, moreover, that, in right-angled spherical triangles, having one side common, the tangents of the hypotenuses are to each other, inversely, as the co-sines of the adjacent angles to the side common.

Theorem 2. In any right-angled spherical triangle it will be, as radius is to the co-sine of one side or leg, so is the co-sine of the other side or leg, to the co-sine of the hypotenuse.

Demonstration. The triangles CEM, CKR , in the last figure, are similar; wherefore it will be, as CE radius, is to CK , the cosine of the side EF , so is MC , the co-sine of the other side DE , to RC , the co-sine of the hypotenuse DF .

Corol. Hence, if two right-angled spherical triangles have the same perpendicular, the co-sines of their hypotenuses will be to each other directly as the co-sines of their bases.

Theorem 3. In any right-angled spherical triangle it will be, as radius is to the sine of either angle adjacent to the hypotenuse, so is the co-sine of the adjacent leg, to the co-sine of the opposite angle.

Demonstration. Produce AC, AE , to F and D , (*fig. 12.*) until they become quadrants. Then, by theorem 1. it will be, as radius to the sine of the angle E , so is the sine of BE , to the sine of the perpendicular BD ; consequently, as radius is to the sine of the angle at E , so is the co-sine of EC , to the co-sine of the angle at A .

Corollary. Hence, in right-angled spherical triangles, having the same perpendicular, the co-sines of the angles at the base will be to each other, directly, as the sines of the vertical angles.

Theorem 4. In any right-angled spherical triangle it will be, as radius is to the sine of the base, so is the tangent of the angle at the base to the tangent of the perpendicular.

Demonstration. Raise up the quadrants, as in theorem 1, until they meet in D ; then the triangles CQV, MEO will be similar, and consequently $CQ : QV :: EM : EO$; but CQ is radius, QV is the tangent of the angle at the base, EM is the sine of the base, and EO is the tangent of the perpendicular. Whence it is, as radius to the tangent of the angle at the base, so is the sine of the base to the tangent of the perpendicular; or by changing the places of the second and third terms, it becomes the theorem required.

Corol. Hence it follows, that, in right-angled spherical triangles having the same perpendicular, the sines of the bases will be to each other, inversely, as the tangents of the angles at the bases.

Theorem 5. In any right-angled spherical triangle it will be, as radius is to the co-sine of the hypotenuse, so is the tangent of either angle to the co-tangent of the other angle.

Demonstration. Produce each side of the right-angled spherical triangle EDB (*fig. 13.*) to the points F, C, A , until they are quadrants; then by the last theorem it will be, as radius to the sine of the base CE , so is the tangent of the angle at E to the tangent of AC : but AC is the complement of the angle at B , and CE that of EB ; wherefore it is, as radius is to the co-sine of the hypotenuse EB , so is the tangent of the angle at E , to the co-tangent of the angle at B .

Lemma. As the sum of the sines of two unequal arches is to their difference, so is the tangent of half the sum of those arches to the tangent of half their difference: and, as the sum of the co-sines is to their difference, so is the co-tangent of half the sum of the arches, to the tangent of half the difference of the same arches.

Demonstration. In the plane triangle ABC (*fig. 14.*) it will be sine $A : BC ::$ sine $C : AB$; then sine $A :$

sine

fine C :: BC : AB, and fine A + fine C : fine A :: BC + AB : BC. Again, fine A - fine C : fine A :: BC - AB : BC; wherefore we have fine A + fine C : fine A - fine C :: BC + AB : BC - AB. But tang. $\frac{1}{2} A + C$: tang. $\frac{1}{2} A - C$:: BC + AB : BC - AB, by plane trigonometry; whence by equality of proportion we have fine A + fine C : fine A - fine C :: tang. $\frac{1}{2} A + C$: tang. $\frac{1}{2} A - C$. Now let the angles ABD, DBC, made by letting fall the perpendicular BD, be the given ones. Then it will be, as the sum of the co-fines of those angles is to their difference, so is the co-tangent of half the sum of those angles to the tangent of half their difference: for it has been already proved, that fine A + fine C : fine A - fine C :: tang. $\frac{1}{2} A + C$: tang. $\frac{1}{2} A - C$. But as the angles A and C are the complements of the given angles, it follows, that the co-fine A + co-fine C : co-fine A - co-fine C :: co-tang. $\frac{1}{2}$ the angles ABD + DBC : tang. of $\frac{1}{2} A - C$, or tang. $\frac{1}{2}$ the difference of the angles ABD, DBC; for the difference of the angles at the base is equal to the difference of the angles made by the perpendicular.

Theorem 6. In any spherical triangle BED (fig. 15.) it will be, as the co-tangent of half the sum of the two sides is to the tangent of half their difference, so is the co-tangent of half the base to the tangent of the distance (EH) of the perpendicular from the middle of the base.

Demonstration. It appears by corollary to theorem 2d, that cof. BE : cof. DE :: cof. BH : cof. DH : hence cof. BE $\pm$ cof. DE : cof. BE :: cof. BH $\pm$ cof. DH : cof. BH; whence cof. BE + cof. DE : cof. BE - cof. DE :: cof. BH + cof. DH : cof. BH - cof. DH. But by the second part of the lemma, co-fine BE + co-fine DE : co-fine BE - cof. DE :: co-tang. $\frac{1}{2} BE + DE$: tang. $\frac{1}{2} BE - DE$; whence by equality of proportion we have co-tang. $\frac{1}{2} BE + DE$: tang. $\frac{1}{2} BE - DE$:: cof. BH + cof. DH : cof. BH - cof. DH. But, by the former part of the lemma, the cofine BH + cof. DH : cof. BH - cof. DH :: co-tang. $\frac{1}{2} BD$: tang. HI; therefore tang. $\frac{1}{2} BE + DE$: tang. $\frac{1}{2} BE - DE$:: co-tang. $\frac{1}{2} BD$: tang. HI.

Corollary. Since the last proportion by permutation becomes co-tang. $\frac{1}{2} BE + DE$: co-tang. $\frac{1}{2} BD$:: tang. $\frac{1}{2} BE - DE$: tang. HI, it will follow, because the tangents of two arches are known to be inversely as their co-tangents, that the tangent of $\frac{1}{2} BD$ is to the tangent of $\frac{1}{2} BE + DE$, as is the tangent of $\frac{1}{2} BE - DE$, to the tangent of HI; that is, the tangent of $\frac{1}{2}$ the base is to the tangent of $\frac{1}{2}$ the sum of the sides, as the tangent of $\frac{1}{2}$ the difference of the sides is to the tangent of the distance of the perpendicular from the middle of the base.

Theorem 7. In any spherical triangle AEB (fig. 16.) it will be, as the co-tangent of half the sum of the angles at the base, is to the tangent of half their difference, so is the tangent of half the vertical angle to the tangent of the angle which the perpendicular EH makes with the line EK bisecting the vertical angle.

Demonstration. By corol. to theorem 3d, it will be, as the co-fine of the angle EAB, is to the co-fine of the angle ABE, so is the fine of the angle AEH to the fine of the angle BEH; whence by composition and division of ratios we have co-fine EAB + co-fine ABE : co-fine EAB - co-fine ABE :: fine AEH + fine BEH : fine AEH - fine BEH. But by the lemma we have co-fine EAB + co-fine ABE : co-fine EAB - cof. ABE :: co-tang. $\frac{1}{2} EAB + ABE$: tang. $\frac{1}{2} EAB - ABE$. And again, by the same lemma, fine AEH + fine BEH : fine AEH - fine BEH :: tang. $\frac{1}{2} AEB$: tang. $\frac{1}{2} AEH - BEH$; whence by writing these proportions in room of the former, we have the following; as the co-tangent of $\frac{1}{2}$ the angles at the base, viz. A + B, is to the tangent of $\frac{1}{2}$ their difference, so is the tangent of $\frac{1}{2} AEB$ to the tangent of the angle KEH, viz. that angle which the perpendicular EH makes with the line EK bisecting the vertical angle AEB.

The Solution of the cases of right-angled spherical Triangles:
See plate CXXXII. fig. 17.

Case	Given	Sought	Solution
1	The hyp. AC and one angle A	The opposite leg BC	As radius : fine hyp. AC :: fine A : fine BC (by the former part of theorem 1.)
2	The hyp. AC and one angle A	The adjacent leg AB	As radius : co-fine of A :: tang. AC : tang. AB (by the latter part of theorem 1.)
3	The hyp. AC and one angle A	The other angle C	As radius : co-fine of AC :: tang. A : co-tang. C (by theorem 5.)
4	The hyp. AC and one leg AB	The other leg BC	As co-fine AB : radius :: co-fine AC : co-fine BC (by theorem 2.)
5	The hyp. AC and one leg AB	The opposite angle C	As fine AC : radius :: fine AB : fine C (by the former part of theorem 1.)
6	The hyp. AC and one leg AB	The adjacent angle A	As tang. AC : tang. AB :: radius : co-fine A (by theorem 1.)
7	One leg AB and the adjacent angle A	The other leg BC	As radius : fine AB :: tang. A : tangent BC (by theorem 4.)
8	One leg AB and the adjacent angle A	The opposite angle C	As radius : fine A :: co-fine of AB : co-fine of C (by theorem 3.)
9	One leg. AB and the adjacent angle A	The hyp. AC	As co-fine of A : radius :: tang. AB tang. AC (by theorem 1.)
10	One leg BC and the opposite angle A	The other leg AB	As tang. A : tang. BC :: radius : fine AB (by theorem 4.)
11	One leg BC and the opposite angle A	The adjacent angle C	As co-fine BC : radius :: co-fine of A : fine C (by theorem 3.)
12	One leg BC and the opposite angle A	The hyp. AC	As fine A : fine BC :: radius : fine AC (by theorem 1.)
13	Both legs AB and BC	The hyp. AC	As radius : co-fine AB :: cof. BC : cof. AC (by theorem 2.)
14	Both legs AB and BC	An angle, suppose A	As fine AB : radius :: tang. BC tang. A (by theorem 4.)
15	Both angles A and C	A leg, suppose AB	As fine A : co-fine C :: radius : co-fine AB (by theorem 3.)
16	Both angles A and C	The hyp. AC	As tang. A : co-tang. C :: radius : cof. AC (by theor. 5.)

Note. The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether AB, C, and AC, be greater or less than 90 degrees each.

The solution of the cases of oblique spherical Triangles.
See plate CXXXII. fig. 18, 19.

Case	Given	Sought	Solution
1	Two sides A C, B C, and an angle A opposite to one of them	The angle B opposite to the other	As fine B C : fine A :: fine A C : fine B (by cor. 1. to theorem 1.) Note, this case is ambiguous when B C is less than A C; since it cannot be determined from the data whether B be acute or obtuse.
2	Two sides A C, B C, and an angle A opposite to one of them	The included angle A C B	Upon A B produced (if need be, let fall the perpendicular C D : Then (by theorem 5,) radius : co-fine A C :: tang. A : co-tang. A C D; but (by cor. 2, to theorem 1.) as tang. B C : tang. A C :: co-fine A C D : co-f. B C D. Whence A C B = A C D ± B C D is known.
3	Two sides A C, B C, and an angle opposite to one of them	The other side A B	As rad. : co-f. A :: tang. A C : tan. A D (by theo. 1.) and (by cor. to theor. 2.) as co-f. A C : co-fine B C :: co-fine A D : co-fine B D. Note, This and the last case are both ambiguous when the first is so.
4	Two sides A C, A B, and the included angle A	The other side B C	As radius : co-fine A :: tang. A C : tang. A D (by theorem 1.) whence B D is also known: Then (by cor. to theorem 2.) as co-fine A D : co-fine B D :: co-fine A C : co-fine B C.
5	Two sides A C, A B, and the included angle A	Either of the other angles, suppose B	As radius : co-fine A :: tang. A C : tang. A D (by theorem 1.) whence B D is known; then (by cor. to theorem 4.) is fine B D : fine A D :: tang. A : tang. B.
6	Two angles A, A C B, and the side A C betwixt them	The other angle B	As radius : co-fine A C :: tang. A : co-tang. A C D (by theorem 5.) whence B C D is also known: Then (by cor. to theorem 3.) as fine A C D : fine B C D :: co-fine A : co-fine B.
7	Two angles A, A C B, and the side A C betwixt them	Either of the other sides, suppose B C	As radius : co-fine A C :: tang. A : co-tang. A C D (by theorem 5.) whence B C D is also known: Then, as co-fine B C D : co-fine A C D :: tang. A C : tang. B C (by cor. 2. to theorem 1.)
8	Two angles A, B, and a side A C opposite to one of them	The side B C opposite the other	As fine B : fine A C :: fine A : fine B C (by cor. 1. to theorem 1.)
9	Two angles A, B, and a side A C opposite to one of them	The side A B betwixt them	As radius : co-fine A :: tang. A C : tang. A D (by theorem 1.) and as tang. B : tang A :: fine A D : fine B D (by cor. to theorem 4) whence A B is also known.
10	Two angles A, B, and a side A C opposite to one of them	The other angle A C B	As radius : co-fine A C :: tang. A : co-tang. A C D (by theorem 5.) and as co-fine A : co-fine B :: fine A C D : fine B C D (by cor. to theorem 3.) whence A C B is also known.

Case	Given	Sought	Solution
11	All the three sides A B, A C, and B C	An angle, suppose A	As tang. $\frac{1}{2}$ A B : tang. $\frac{AC+BC}{2}$:: tang. $\frac{AC-BC}{2}$: tang. D E, the distance of the perpendicular from the middle of the base (by cor. to theorem 6.) whence A D is known: Then, as tang. A C : tang. A D :: radius : co-fine A (by theor. 1.)
12	All the three angles A, B, and A C B	A side, suppose A C	As co-tang. $\frac{ABC+A}{2}$: tangent $\frac{ABC-A}{2}$:: tang. $\frac{ACB}{2}$: tang. of the angle included by the perpendicular and a line bisecting the vertical angle; whence A C D is also known: Then (by theorem 5.) tang. A : co-tang. A C D :: radius co-fine A C.

Note, In letting fall your perpendicular, let it always be from the end of a given side and opposite to a given angle.

TRILLION, in arithmetic, the number of a billion of billions.

After billions we reckon by trillions, which makes a class of numeration, and is divided, like the other classes, into three places: thus we say, trillions; tens of trillions; hundreds of trillions, &c.

TRIM, *of a ship*, her best posture, proportion of ballast, and hanging of her masts, &c. for sailing. To find the trim of a ship, is to find the best way of making her sail swiftly, or how she will sail best. This is done by easing of her masts and shrouds; some ships sailing much better when they are slack, than when they are taut or fast: but this depends much upon experience and judgment, and the several trials and observations which the commander and other officers may make abroad.

TRIMACRUS, or TRIMACER, a foot, in ancient poetry, the same with the molossus.

TRIMMERS, in architecture, pieces of timber framed at right-angles to the joints, against the ways for chimneys, and well-holes for stairs.

TRINE, in astrology, the aspect or situation of one star with regard to another, when they are distant 120 degrees: it is noted with this character Δ .

TRINGA, in ornithology, a genus of birds belonging to the order of the scolopaces, the characters of which are these: the beak is of a cylindric figure, obtuse at the extremity, and in length about equal to the toes: the feet have each four toes, and they are connected.

To this genus belongs the ruff, the cinclus, the lapwing, the godwit, the tolk, grey plover, &c.

TRINGLE, in architecture, a name common to several little square members or ornaments, as reglets, listels, and platbands.

TRINGLE is more particularly used for a little member fixed exactly over every triglyph, under the plat-band of the architrave, from whence the guttæ or pendant drops hang down.

TRINITARIANS, those who are orthodox and believe in the Trinity: those who do not believe therein, being called Antitrinitarians.

TRINITARIANS also denote an order of religious instituted at Rome in the year 1198, under the pontificate of Innocent III. the founders of which were John de Matha, and Felix de Valois. John de Matha was born of noble parents in Provence, and took his degree of doctor in the university of Paris. Felix de Valois, so called from the country of Valois, lived as a hermit in a wood, in the diocese of Meaux. John de Matha, having had a vision of an angel presenting two captives to him, and thereupon resolving to devote himself to a religious life, joined himself with Felix de Valois, and these

these two saints lived together in the practice of virtue and all manner of austerities. One day, the story says, they observed a large white stag, who brought into the middle of the wood a red and blue cross. This wonderful sight, added to John de Matha's vision, made them conclude, that God required something in particular of them; and soon after an angel, in a dream, ordered them to go to Rome, where the pope would inform them what they must do. Innocent III. received them with great humanity, and, being convinced of their sanctity, gave them permission to establish a new order, whose principal end should be to labour for the deliverance of captives, who groaned under the tyranny of the infidels. The same pope gave them a habit, which was a white gown ornamented with a red and blue cross, in memory of the apparition of the stag; and gave this new order the title of the Holy Trinity.

John de Matha and Felix de Valois being returned into France, king Philip Augustus consented to the establishment of their order in that kingdom. Accordingly a convent was built in the place where they had the vision of the stag, and was from thence called Cerfroy. This monastery was endowed by Margaret countess of Burgundy, for the maintenance of twenty religious. John de Matha, seeing his order established, sent John Anglicus and William Scot, two Englishmen, to Morocco, in Africa, to treat with Miramolin for the redemption of poor Christian captives. This negotiation succeeded so well, that, in the year 1200, they redeemed 186 slaves. The same year, they had a convent given them in the territory of Honscott in Flanders, and another at Arles in Provence. Afterward John de Matha took a journey into Spain, where he prevailed upon the kings and princes of that country to make several settlements for the redemption of Christian captives. In the mean time, Felix de Valois gained an establishment at Paris, in a place where was a chapel dedicated to St. Mathurin; from whence this order had the name of Mathurins. After the death of the two holy founders, pope Honorius III. confirmed the order, and their rule was approved by his successor Clement IV. in 1267. At first they were not permitted to eat any flesh meat, and, when they travelled, they were to ride only upon asses. But their rule was corrected and mitigated by the bishop of Paris, and the abbots of St. Victor and St. Genevieve: and they were allowed to eat meat, and to use horses.

This order possesses two hundred and fifty convents, divided into thirteen provinces: six of these are in France; namely, France, Normandy, Picardy, Champagne, Languedoc, and Provence: three are in Spain; namely, New Castile, Old Castile, and Arragon: one in Italy, and one in Portugal. There was formerly the province of England, where this order had forty-three houses; that of Scotland, where it had nine; and that of Ireland, where it had fifty-two; besides a great number of monasteries in Saxony, Hungary, Bohemia, and other countries. The convent of Cerfroy, in France, is head of the order.

In 1573, a reform of this order was began by Julian de Nantonville and Claude Aleph, two hermits of St. Michael, who obtained leave of the pope to take the habit of the Trinity; whereupon their hermitage was converted into a house of the order. The principal articles of the reform were, that they should observe the primitive rules approved by Clement IV. should abstain from flesh, use woollen shirts, and have matins at midnight. This reform was not embraced by the whole order, till 1635, when Cardinal Rochefoucault, by order of pope Urban VIII. introduced it into all the houses of the Trinitarians. Those of Spain, in 1594, added to the reform the going bare-footed; for which reason, in that country, they began to be called bare-footed Trinitarians. There are also bare-footed Trinitarians in France, established by F. Jerom Hallies.

There are also nuns of the Trinitarian order, in Spain, established by John de Matha himself, who built them a convent in 1201, under the direction of the infant Constantia, daughter of Peter II. king of Arragon; who was the first religious, and the first superior of the order. And, in 1612, Frances de Romero, daughter of Julian de Romero, lieutenant general of the Spanish

army, founded a convent of bare-footed Trinitarian nuns at Madrid.

TRINITY, *Trinitas*, in theology, the ineffable mystery of three persons in one God, Father, Son, and Holy Spirit. See God, &c.

The doctrine of the Trinity, as professed in the Christian church, is as follows; that there is but one God in three distinct persons, Father, Son, and Holy Ghost; *person* signifying the same as *essence*, with a particular manner of subsistence, which the Greek fathers call hypostasis, taking it for the incommunicable property that makes a person. The Father, Son, and Holy Ghost are believed to be three distinct persons in the divine nature, because the scriptures in speaking of these three distinguish them from one another, as we use in common speech to distinguish three several persons. There are many instances to this purpose; particularly the form of administering the sacrament of baptism, which runs in the name of the Father, the Son, and the Holy Ghost: and that solemn benediction, with which St. Paul concludes his second epistle to the Corinthians: "The grace of our Lord Jesus Christ, &c." and the three witnesses in heaven, mentioned by St. John. Each of these three persons are affirmed to be God, because the names, properties, and operations of God are, in the holy scripture, attributed to each of them.

The divinity of the Father is undisputed. That of the Son is proved from the following texts, among many others. St. John says, "The Word was God;" St. Paul, "That God was manifested in the flesh; that Christ is over all, God blessed for ever." Eternity is attributed to the Son: "The Son hath life in himself:" perfection of knowledge: "As the Father knoweth me, so know I the Father." And we are commanded, "to honour the Son, as we honour the Father." The divinity of the Holy Ghost rests upon the following proofs, among others: Lying to the Holy Ghost, is called "lying to God:" because Christians are the temples of the Holy Ghost, they are said to be the "temples of God." "His teaching all things; his guiding into all truth; his telling things to come; his searching all things, even the deep things of God, &c." are adduced as plain characters of his divinity. Besides, he is joined with God the Father, as an object of faith and worship, in baptism, and the apostolical benediction.

This doctrine is called a mystery, because we are not able to comprehend the particular manner of the existence of the three persons in the divine nature. But tho' a doctrine be above reason, it is not therefore contrary to reason; and the perfections of the divine nature being infinite, must consequently be above our reach. As to the seeming contradiction of a Unity in Trinity and Trinity in Unity, that is, of One being Three and Three One; the answer is, that it is not affirmed, they are One and Three in the same respect; that the divine essence can be but one, and therefore there can be no more Gods than one: but because the scriptures, which assure us of the unity of the divine essence, do likewise with the Father join the Son and Holy Ghost, in the same attributes, operations, and worship, therefore they are capable of number as to their relation to each other, though not as to their essence, which is but one.

The school divines have taken great pains to perplex this doctrine with nice distinctions, and an unintelligible jargon. Thus they tell us, there is, in God, one Essence, two Processions, three Persons, four Relations, five Notions, and the Perichoresis, Circumcession, or Mutual in-dwelling of the three persons. The Son, they say, proceeds from the Father by generation, but the Holy Ghost by spiration: they talk of paternity and filiation, and distinguish between active and passive spiration; with much cant of this sort, which cannot easily be explained or understood.

It is evident from ecclesiastical history, that the devotions of the ancient church were paid to every person of the Trinity. St. Stephen, the proto-martyr, breathed his last in a prayer to Christ; and St. Paul always baptized in the name of Christ.

In the second century, Pliny, who took the confession of some revolting Christians, tells us, they declared to him, that they used to meet on a certain day, before

it was light, and, among other parts of their worship, sing a hymn to Christ, as their God. Not long after this, lived Polycarp, who joins God the Father and the Son together, in his prayers for grace and benediction upon men. Soon after lived Justin Martyr, who, to wipe off the charge of atheism brought against the Christians, declares, that they worshipped the God of righteousness, and his Son, as also the Holy spirit of prophecy. Minucius Felix, in answer to an objection, that the Christians worshipped a crucified man, says, He, whom they worshipped, was God, and not a meer mortal man. Irenæus, speaking of the miracles wrought by the Christians in his time, assures us, they were done, not by magic or enchantment, but by invocation of the name of Christ. To these may be added the testimonies of Theophilus bishop of Antioch, Clemens Alexandrinus, and Tertullian, the last writer of the second age. In the third century, we have an illustrious testimony of the worship of Christ, as God, in the fragments of Caius, a Roman presbyter, preserved by Eusebius. And Origen, in particular, asserts the worship of Christ, against the common objection, renewed by Celsus, that the Christians worshipped one who had but lately appeared in the world. Add to these the testimonies of St. Cyprian, Arnobius, and Lactantius. As that age abounded in martyrs, so those holy men usually directed their last prayer to Christ, in imitation of St. Stephen; instances of which practice are innumerable.

That they paid divine worship to the Holy Ghost also, appears from the above-cited testimonies. For Polycarp's doxology is to the whole Trinity; and Justin Martyr declares, that the object of their worship was the whole Trinity. To which may be added the plain testimony of Origen, who, comparing the practice of heathens and Christians, says, The former, having forsaken the Creator, worshipped the creature, but the latter worshipped and adored no creature, but only the Father, Son, and Holy Spirit. In Tertullian's time, the worship of the Holy Ghost was so common in the church, that Praxeas, and other Unitarians, charged the catholics with Tritheism, or the worship of three Gods, upon that account.

Christians, in many places, have fallen into the absurdity, if not blasphemy, of making visible representations of the mystery of the Trinity. Bishop Burnet tells us, that before the Reformation, it was usual, in England, to have pictures of the Trinity. God the Father was generally represented in the shape of an old man, with a triple crown, and rays about his head. The Son, in another part of the picture, looked like a young man, with a single crown on his head, and a radiant countenance. The blessed virgin was between them, in a sitting posture; and the Holy Ghost, under the appearance of a dove, spread his wings over her. This picture, he tells us, is still to be seen in a prayer-book, printed in the year 1526, according to the ceremonial of Salisbury. Skippon tells us, there is, at Padua, a representation of the Trinity, being the figure of an old man, with three faces and three beards.

Many of the heathens seem to have had a notion of a Trinity in the Godhead; and Plato and his followers speak of it in such terms, that the primitive Fathers have been accused of borrowing the very doctrine from the Platonic school. This point is treated at large in Cudworth's Intellectual System.

The several Anti-trinitarian heresies may be seen under their respective articles. See ARIANS, SABELIANS, SOCINIANS, &c.

TRINITY-SUNDAY, a festival of the Christian church, observed on the Sunday next after Whitsunday in honour of the Holy and undivided Trinity. The observation of this festival was first enjoined in the council of Arles, anno 1260.

TRINITY-HOUSE, a society founded in the year 1515, by Sir Thomas Spert, Knt. commander of the great ship Henry Grace de Dieu, and comptroller of the navy to Henry VIII. for the regulation of seamen, and the convenience of ships and mariners on our coast, and incorporated by the above-mentioned prince, who confirmed to them not only the ancient rights and privileges of the company of mariners of England, but their se-

veral possessions at Deptford; which, together with the grants of queen Elizabeth and king Charles II. were also confirmed by letters patent of the first of James II. in 1685, by the name of "The master, wardens and assistants of the guild or fraternity of the most glorious and undivided Trinity, and of St. Clement, in the parish of Deptford Stroud, in the county of Kent."

This corporation is governed by a master, four wardens, eight assistants, and eighteen elder brethren; but the inferior members of the fraternity, named younger brethren, are of an unlimited number; for every master, or mate, expert in navigation may be admitted as such; and these serve as a continual nursery to supply the vacancies among the elder brethren, when removed by death, or otherwise.

The master, wardens, assistants, and elder brethren, are by charter invested with the following powers:

1. That of examining the mathematical children of Christ's hospital.
2. The examination of the masters of his majesty's ships; the appointing pilots to conduct ships in and out of the river Thames; and the amercing all such as shall presume to act as master of a ship of war or pilot, without their approbation, in a pecuniary mulct of twenty shillings.
3. The settling the several rates of pilotage, and erecting light-houses, and other sea-marks upon the several coasts of the kingdom, for the security of navigation; to which light-houses all ships pay one halfpenny a ton.
4. The granting licenses to poor seamen, not free of the city, to row on the river Thames, for their support, in the intervals of sea-service, or when past going to sea.
5. The preventing of aliens from serving on board English ships, without their license, upon the penalty of five pounds, for each offence.
6. The punishing seamen for desertion, or mutiny, in the merchants service.
7. The hearing and determining the complaints of officers and seamen in the merchants service; but subject to an appeal to the lords of the Admiralty, or the judge of the court of Admiralty.

To this company belongs the ballast office, for clearing and deepening the river Thames, by taking from thence a sufficient quantity of ballast, for the supply of all ships that sail out of that river; in which service sixty barges with two men in each, are constantly employed; and all ships that take in ballast pay them one shilling a ton, for which it is brought to the ship's sides.

In consideration of the great increase of the poor of this fraternity, they are by their charter impowered to purchase in mortmain lands, tenements, &c. to the amount of five hundred pounds per annum; and also to receive charitable benefactions of well disposed persons, to the like amount of five hundred pounds per annum, clear of reprises.

There are annually relieved by this company about three thousand poor seamen, their widows, and orphans, at the expence of about six thousand pounds.

They commonly meet to choose their master at their house at Deptford; but are not obliged to do it there. Their meetings are generally on Wednesdays and Saturdays, at their house in Water lane, Thames street; but their courts are not constantly fixed to a set time.

Fraternity of the TRINITY, a religious society instituted at Rome by St. Philip Neri, in 1548. These religious were appointed to take care of the pilgrims who came to visit the tombs of St. Peter and St. Paul. The society originally consisted of only fifteen religious, who assembled on the first Sunday of every month, in the church of St. Saviour del Campo, to hear the exhortations of the founder; after whose death pope Paul IV. gave the fraternity the church of St. Benedict, near which they have since built a large hospital for the reception of pilgrims. The fraternity is one of the most considerable in Rome, and most of the nobility of both sexes have been members thereof.

TRINOMIAL, or **TRINOMIAL-ROOT**, in mathematics, is a root consisting of three parts connected together by the signs + or -, as $x+y+z$, or $a+b-c$.

TRIO, in music, a part of concert wherein three persons sing; or more properly a musical composition consisting of three parts. Trios are the finest kinds of composition, and these are what please most in concerts.

TRIOCTILE,

TRI

TRIOCTILE, in astrology, an aspect or situation of two planets with regard to the earth, when they are three octants or eight parts of a circle, that is, 135° distant from each other. This aspect, which some call the self-quadrans, is one of the new aspects superadded to the old ones by Kepler.

TRIONES, in astronomy, a sort of constellation or assemblage of several stars in the ura minor, commonly called Charles's wain.

TRIONUM, in botany, a genus of plants, the corolla whereof consists of five patent petals, vertically cordated, and united together at the base: the fruit is an ovated quinquangular capsule, consisting of five cells, and containing five valves: the seeds are numerous, and kidney-shaped.

TRIOPTERIS, in botany, a genus of plants, the corolla whereof consists of six oval, erecto-patulous, equal and permanent petals, surrounded by three others smaller than themselves, but equal to one another: there is no pericarpium: the seeds are three, erect and carinated at the back; each of them has externally at its base an ala, and at its apex two; these ala are what in the flowering state of the plant appear to be petals, but they are not truly such.

TRIOSTEUM, in botany, a genus of plants, the flower of which has a permanent empalement of one leaf, cut into five segments; it has a tubulous flower of one petal, with a short brim, cut into five parts, which stand erect, and five slender stamina the length of the tube, terminated by oblong summits, with a roundish germen, supporting a cylindrical style, crowned by a thick stigma. The germen afterward becomes an oval berry with three cells, each including one hard, three-crowned, obtuse seed.

There are two species of this plant. The first sort grows naturally in the woods in several parts of North America; and the root is composed of thick fleshy fibres, which are contorted and rough, from which spring several strong herbaceous stalks a foot and a half high, garnished at each joint by two oblong broad leaves, sitting close to the stalk. From the bosoms of these come out the flowers in whorls, sitting very close to the stalks; the empalements are cut into five segments. The flowers are small, tubulous, of a dark red colour, and cut slightly at the brim into five obtuse segments, and are succeeded by roundish berries, which turn yellow when ripe, having three cells, in each of which is contained one hard seed. The root is perennial, but the stalks decay every autumn.

The second sort differs from the first in its leaves, being longer and narrower. The flowers stand single upon short foot-stalks, but two at each joint, whereas the other has many growing in whorls round the stalks; but the roots of both are indifferently used in America by the title of Dr. Tinkar's weed.

Both these plants are natives of Virginia, and some other northern parts of America, where their roots have been frequently used as an emetic, and are commonly called ipecacuana. One of the first persons who brought the roots into use was Dr. Tinkar, from whence many of the inhabitants have called them by the name of Dr. Tinkar's weed, as hath been already observed. The leaves of the first sort greatly resemble those of the true ipecacuana, but the roots are of a different form; but so far as I can judge, says Mr. Miller, by the imperfect fruit of a specimen in my collection of the true ipecacuana, as also by the figure and description given by Piso in his history of Brasil, it seems to belong to this genus.

The first sort grows on low marshy grounds, near Boston in New-England, very plentifully, where the roots are taken up every year, and are continued in use amongst the inhabitants of Boston.

This plant is preserved in several curious gardens in England, and is hardy enough to thrive in the open air; but it should be planted on a moist, light, soil; for if it is on a dry ground, there must be care taken to water the plants constantly in dry weather, otherwise they will not thrive.

TRI

It may be propagated by seeds, which should be sown in autumn, on a border of light earth, exposed to the morning sun; for if the seeds are sown in the spring, they will remain in the ground a whole year before the plants will come up, so that during this time the border must be constantly kept clear from weeds; the following spring, when the plants appear, they should be duly watered in dry weather, which will greatly promote their growth; but if the seeds are sown in autumn, the plants will come up the following spring, and must be constantly kept clean from weeds, which, if permitted to grow amongst them, will soon over-bear the plants while they are young, and either quite destroy them, or so much weaken them, that they will not recover in a long time.

The plants may remain in this seed-border until the Michaelmas following, when they should be carefully taken up, and transplanted where they are designed to remain. Some of them should be planted in pots, that they may be sheltered in winter, lest those which are in the full ground should be destroyed by severe frost.

They may be also propagated by parting of the roots. The best season for this work is in the spring, just before the plants begin to shoot, which is commonly about the middle or latter end of March; but in doing of this, the roots must not be parted too small, for that will prevent their flowering strong.

These plants perfect their seeds in this country every year, if sown in autumn as soon as they are ripe, which is the best way to propagate them. The seedling plants will not flower until the third year, and then they are seldom so strong as the older plants.

TRIP, a sea term. A ship is said to bear her top-sails a-trip, when she carries them hoisted up to the highest.

TRIPARTITE, something divided into three parts, or made by three parties, as indenture tripartite, &c.

TRIPARTITION, a division by three, or the taking the third part of any number or quantity.

TRIPELAS, in natural history, earths composed of similar particles, naturally dry, and of rough dusty surfaces, but somewhat more firmly coherent than the ochres, composed of fine but hard particles, and not readily diffusible in water. Of this genus of earths authors make five species, which may be reduced to the yellowish and the reddish; for an account of which, see the article **TRIPOLI**.

TRIPENTAHÆDRIA, in natural history, the name of a genus of spars, composed of thrice five planes, being made of a pentangular column, terminated at each end by a pentangular pyramid. Of this genus we have only one species: this has a moderately long column, and very short and broad pyramids; it is found in Derbyshire, Yorkshire, and Cornwall, and is frequently about Gosselaer, in Saxony.

TRIPHTHONGUE, in grammar, an assemblage or concurrence of three vowels in the same syllable, as *que*.

TRIPLE, in music, is one of the species of measure or time.

Triple-time consists of many different species, of which there are in general four, each of which has its varieties. The common name triple is taken hence, that the whole half of the bar is divisible into three parts, and is beaten accordingly. The first species is called the simple triple, wherein the measure is equal to three semibreves, three minims, three crotchets, three quavers, or three semiquavers, which are marked thus, $\frac{3}{4}$, $\frac{3}{8}$, $\frac{3}{16}$, but the last is not much used, except in church music. In all these the measure is divided into three equal parts or times, called thence triple-time, or the measure of three times; of which two are beat down, and the third up. The second species is the mixed triple; its measure is equal to six crotchets, or six quavers, or six semiquavers, and accordingly is marked $\frac{6}{4}$, or $\frac{6}{8}$ or $\frac{6}{16}$; but the last is seldom used. The measure here is usually divided into equal parts or times, of which one is beat down and one up; but it may also be divided into six times, of which the first two are beat down and the third up, then the next two down and the last up; that is, each half of the measure is beat like the simple triple,

triple, on which account it may be called the compound triple, and because it may be thus divided either into two or six times, that is, two triples, it is called mixed, and by some the measure of six times. The third species is the compound triple, consisting of nine crotchets or quavers, or semi-quavers, marked $\frac{3}{4}$, $\frac{3}{8}$, $\frac{3}{16}$; the first and last are little used: some also add $\frac{3}{2}$, $\frac{3}{4}$, which are never used; some add also other two, viz. six semi-breves and six minims, marked $\frac{6}{4}$ or $\frac{6}{8}$, but these are not in use. This measure is divided into three equal parts or times, whereof two are beat down and one up; or each third part may be divided into three times, and beat like the simple triple, on which account it is called the measure of the nine times. The fourth species is a compound measure of the second species, containing twelve crotchets or quavers, or semi-quavers, marked $\frac{12}{4}$, $\frac{12}{8}$, $\frac{12}{16}$, to which some add $\frac{12}{2}$ and $\frac{12}{4}$, which are never used; nor are the first and third much used; especially the latter. The measure here may be divided into two times, and beat one down and one up; or each half may be divided and beat as the second species, either by two or three, in which case it will make in all twelve times; and hence it is called the measure of twelve times. The French and Italian authors make a great many more species and divisions of triple-time, unknown, or at least unregarded, by our English musicians, and therefore not necessary to be dwelt on here.

TRIPLICATE RATIO, the ratio which cubes bear to one another. See **CUBE**.

This ratio is to be distinguished from triple ratio, and may be thus conceived. In the geometrical proportions 2, 4, 8, 16, 32, as the ratio of the first term (2) is to the third (8) duplicate of that of the first to the second, or of the second to the third, so the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of that of the second to the third, or of that of the third to the fourth, as being compounded of three equal ratios.

TRIPPLICITY, or **TRIGON**, among astrologers, is a division of the signs according to the number of the elements, each division consisting of three signs. Triplicity is frequently confounded with trine aspect, tho' strictly speaking the two are very different things; as triplicity is only used with regard to the signs, and trine, on the contrary, with regard to the planets. The signs of triplicity are those which are of the same nature, and not those which are in trine aspect. Thus Leo, Sagittarius, and Aries, are signs of triplicity, because those signs are by these writers all supposed fiery.

TRIPOD, *Tripos*, in antiquity, a famed sacred seat or stool, supported by three feet, whereon the priests and sibyls were placed to render oracles. It was on the tripod that the gods were said to inspire the Pythians with that divine fury and enthusiasm wherewith they were seized at the delivery of their predictions.

TRIPOLI, a state of Africa, which including Barca, is bounded by the Mediterranean-sea on the north, by Egypt on the east, by Nubia and Biledulgerid on the south, and by Tunis on the west; extending along the shore of the Mediterranean from the north-west to the south-east about a thousand miles, but scarce two hundred miles broad in any place. The city of Tripoli, being the capital of this state, is surrounded with a wall and other fortifications: east long. 14 deg. 30 min. north lat. 33 deg. 30 min.

TRIPOLI, in natural history, the name of an earthy substance, much used by the lapidaries to polish stones, and by the braziers, and other the like artists, to clean metalline vessels. It is of two kinds, the yellowish, and reddish-white; the yellowish white kind is called by authors alana gleba, tripolis and terra tripolitana; this is the produce of Germany, Saxony, and France; there is also of it in the neighbourhood of Venice, but it is found in greatest plenty in many parts of Africa. It is found a dry hard earth, of a very pale yellowish-white, of a firm texture, and moderately heavy; it is sometimes found of itself, constituting a stratum; but it is more frequently met with in detached pieces among strata of other matter. It is of a rough, irregular, dusty surface; it adheres slightly to the tongue, is dry, hard, and harsh to the touch, is not to be broken between the fingers, and

slightly stains the hands: it makes no effervescence with aqua fortis, and makes a slight hissing noise on being thrown into water. The reddish tripoli is of our own production, though not peculiar to our country; it is found in great abundance on Mendip-hills in Somersetshire, and not less plentifully in many parts of Germany. This is well known in the shops as a substance of great use in polishing brass, but is not applied to any of the other uses of the yellowish kind: this, like the former, is most frequently found in detached masses, and while in the earth is tolerably soft, and easily falls into flakes. When dry it becomes of a considerable hardness, and is of a fine pale reddish-white, of a loose open texture, composed of a multitude of extremely thin plates or flakes laid evenly on one another, and considerably heavy; it is of a smooth and somewhat glossy surface; it adheres very firmly to the tongue, is dry and harsh to the touch, too hard to be broken between the fingers, and does not stain the hands: it makes no effervescence with acids, and burns to a paler colour, with some additional hardness.

TRIPPING, in heraldry, denotes the quick motion of all sorts of deer, and of some other creatures, represented with one foot as it were on a trot.

TRIPTOTES, *Triptota*, in grammar, defective nouns which have only three cases; such is *mele*, *tempe*, *grates*, *prece*, &c.

TRIQUETROUS, among botanists, expresses a fruit or leaf that has three sides or faces all flat. This leaf is usually subulate, or grows gradually smaller from the base to the point.

TRIEME, or **TRIEMIS**, in antiquity, a gally with three ranks of oars on a side.

TRISECTION, or **TRISSECTION**, the dividing a thing into three. The term is chiefly used in geometry, for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in this respect on a footing with the quadrature of the circle, and the duplicature of the cube angle.

TRISMEGISTUS, an epithet or surname given to one of the two Hermeses, or Mercuries, kings of Thebes in Egypt, who is said to be contemporary with Moses.

TRISOLYMPIONICA, amongst the ancients, a person who had thrice borne away the prize at the Olympic games; these had great privileges and honours paid them.

TRISPAST, *Trispaston*, in mechanics, a machine with three pulleys, or an assemblage of three pulleys for raising of great weights.

TRISYLLABLE, or **TRISSYLLABLE**, in grammar, a word consisting of three syllables.

TRITE, in music, the third musical chord in the system of the ancients.

TRITICEA, the name whereby some authors call the triticum. See the next article.

TRITICUM, in botany, a genus of plants, the corolla whereof consists of two valves, nearly equal in size, and of the bigness of those of the cup. The exterior valve is bellied with an obtuse end, terminated by a point; the interior valve is plane. The corolla serves instead of a pericarpium, inclosing the seed, which is single, obtuse, and furrowed on one side.

This genus comprehends the common wheat, the spelt-corn, and couch-grass. See **WHEAT**, &c.

TRITON, in ichthyology, a genus of fish, the body of which is oblong, the rostrum at the mouth of a spiral form, the tentacula fourteen in number, and twelve of them cheliferous.

TRITON, in poetry, a sea-demi-god, held by the ancients to be an officer or trumpeter of Neptune, attending on him, and carrying his orders and commands from sea to sea.

The poets represent him as a half man, half-fish, terminating in a dolphin's tail, and bearing in one hand a sea-shell, which serves as a trumpet. Some of the ancients make him the son of Neptune and the nymph Salacia; Hesiod, of Neptune and Amphitrite; Neume-nius, in his book *De Piscationibus*, makes him the son of Oceanus and Tethys; and Lycophron, the son of Nereus. But, though Hesiod and the mythologists only speak of one Triton, the poets have imagined several,

giving some of them for trumpeters to all the sea-gods, particularly to Neptune and Venus; accordingly they were frequently introduced on the antient theatres, in the Naumachia.

TRITONE, *Tritono*, in music, a false concord consisting of three tones, or a greater third and a greater tone.

Its ratio or proportion in numbers is of 45 to 32. In dividing the octave we find on one side the false fifth, and the tritone on the other.

The tritone is a kind of redundant fourth, consisting of three tones, whence its name; or more properly of two tones, with a greater semi-tone and a lesser, as of *ut* to *fa*, sharp; of *fa* to *si*, flat, &c. But it is not, as many imagine, a greater fourth, for the fourth is a perfect interval, which does not admit of any majority or minority; nor must the tritone be confounded with the false fifth, for the tritone only comprehends four degrees, viz. *ut*, *re*, *mi*, *fa*, sharp; whereas the false fifth comprehends five, viz. *fa*, sharp, *sol*, *la*, *si*, *ut*. Besides that, among the six semi-tones, which compose the tritone chromatically, there are three greater and three lesser; whereas, among the six semi-tones, which compose the false fifth, there are only two lesser and four greater.

TRITURATION, *Tritura*, in pharmacy, the act of reducing a solid body into a subtile powder; called also levigation and pulverization. See **LEVIGATION** and **PULVERIZATION**.

This is principally employed to reduce hard substances to fine powders, either by the mortar, or by way of levigation on a marble: there is little difficulty in this, besides the labour. Trituration has a great share in some instances, in raising or depressing the efficacy of what comes under its management; for in grinding all those bodies, whose efficacy consists in the peculiar shape and points of their component parts, the more and finer they are broke, the less they will operate: thus may calomel be rendered much gentler, and made capable of being given in much larger quantities, only by long rubbing in a glass mortar; for the continual triture has the same effect upon it, as repeated sublimation, which is only breaking of the saline spicula more and more, until it becomes almost plain mercury. But in resinous substances, particularly those which are purgative, as jalap, scammony, &c. the finer the powder they are reduced into, the greater their efficacy is likely to be. As the sense which the stomach and bowels have of them, is in proportion to their contacts, therefore the more the same quantity is divided, the farther will it diffuse itself, and vellicate the fibres; that is, in other words, it will work the more.

TRITURATION, is also used in medicine for the action of the stomach on the food, whereby it is fitted for nourishment.

TRIUMFETTA, in botany, a genus of plants, the flower of which has no empalement, but it has five linear, erect, obtuse petals, which turn inward; it has ten awl-shaped rising stamina the length of the petals, terminated by single summits, and a roundish germen, supporting a style the length of the stamina, crowned by an acute bifid stigma. The germen afterward becomes a globular capsule, set with long prickles on every side, having four cells, each containing one seed, which is convex on one side, and angular on the other.

There are two species of this plant. The first sort grows naturally in Jamaica and most of the other islands in the West-Indies; it rises with an upright stem to the height of six or seven feet, which becomes ligneous toward the bottom, dividing upward into four or five branches, garnished with leaves, placed alternately, divided almost into three lobes toward the top, ending in acute points; they are covered with a soft brown down on their under side, but their upper is of a yellowish green; their borders are acutely but unequally sawed, standing upon foot-stalks an inch long. The branches are terminated by long spikes of flowers, and from the side of the stalk come out several small clusters. The flowers are small, the petals narrow, of a yellow colour; these are succeeded by burry capsules, something like those of the agrimony, but rounder; the prickles are longer than those, and are placed on every side. This plant generally flowers

here in July and August, and in warm seasons the seeds do sometimes ripen.

The second sort grows naturally in India; it is an annual plant, rising near three feet high; the stalks are ligneous, branching out toward the top into three or four slender branches, garnished with entire leaves, sawed on their edges, ending in acute points, and are terminated by small clusters of pale yellow flowers standing upon pretty long foot-stalks. The empalements of the flowers are cut into five narrow segments, but soon fall off; the flower has five erect petals, and generally ten slender stamina, terminated by roundish summits, with a roundish germen, supporting one hairy style, crowned by a single stigma. The germen afterward becomes a round prickly capsule with four or five cells, each including one seed.

These sorts are both propagated by seeds, which must be sown on a hot-bed early in the spring; and when the plants come up, and have four or five leaves, they should be each transplanted into a separate pot, and plunged into a moderate hot-bed of tanners bark, shading them from the sun until they have taken new root; then they must be treated in the same manner as other tender exotic plants. During the summer-season the plants may remain in this hot-bed, but in autumn the first must be removed into the stove, and plunged into the bark-bed. If the plants live through the winter, they will flower the following summer, so will ripen their seeds in autumn; but they may be continued two years, provided they are carefully managed.

The second sort is annual; so, if the plants are brought forward early in summer, they will flower in autumn, but must be removed into a stove to perfect the seeds, which seldom ripen in England before Christmas.

TRIUMPH, *triumphus*, a solemnity practised by the ancient Romans, to do honour to a victorious general.

There were two sorts of triumphs, the greater and the lesser, particularly called ovation: of these, the triumph was much the more splendid procession. None were capable of this honour, but the dictator, consuls, and prætors; though there are examples to the contrary, as particularly in Pompey the Great, who had a triumph decreed him when he was only a Roman knight, and had not yet reached the senatorial age. The triumph was the most pompous shew among the ancients: authors usually attribute its invention to Bacchus, and tell us that he first triumphed upon the conquest of the Indies, and yet this ceremony was only in use among the Romans. The Grecians had a custom which resembled the Roman triumph; for the conquerors used to make a procession through the middle of their city, crowned with garlands, repeating hymns and songs, and brandishing their spears: the captives were also led by them, and all the spoils exposed to public view. The order of a Roman triumph was briefly thus: The senate having decreed the general a triumph, and appointed a day, they went out of the city-gate to meet the conqueror, and marched in order with him through the city. The cavalcade was led up by the musicians, who had crowns on their heads; after them came several chariots, with plans and maps of the cities and countries subdued, done in relieve: they were followed by the spoils taken from the enemy, their horses, arms, gold, silver, machines, tents, &c. After these came the kings, princes, or generals subdued, laden with chains, and followed by mimics or buffoons, who insulted over their misfortunes. Next came the officers of the conquering troops with crowns on their heads. Then appeared the triumphal chariot, in which was the conqueror richly clad, in a purple robe embroidered with figures of gold, setting forth his glorious achievements: his buskins were beset with pearl, and he wore a crown, which at first was only laurel, but afterwards gold. One hand held a laurel branch, the other a truncheon. At his feet were his children, or sometimes on the chariot horses. It is added, that the public executioner was behind him, to remind him from time to time that these honours were transitory, and could not screen him from the severity of the laws, if he should ever be found delinquent. As the triumphal chariot passed along, they strewed flowers before it. The music played in the praise of the conqueror,

amidst the loud acclamations of the people crying *Io Triumphe*. The chariot was followed by the senate clad in white robes, and the senate by such citizens as had been set at liberty or ransomed. The procession was closed by the sacrificers, and their officers and utensils, with a white ox led along for the chief victim. In this order they proceeded through triumphal arches to the Capitol, where the victims were slain. In the mean time all the temples were open; the altars laden with offerings and incense; games and combats were celebrated in the public places, and rejoicings appeared every where. What was horrible amidst all this mirth, was, that the captives, when arrived at the Forum, were led back to prison and strangled: it being a point of religion with them not to touch the victims till they had taken full revenge of their enemies. The rites and sacrifices over, the triumpher treated the people in the Capitol, under the porticoes, and sometimes in the temple of Hercules.

An ingenious author observes, that it was the greatest diminution of the Roman glory imaginable, that, in their institution of public triumphs, they led their enemies in chains, when they were prisoners. It is to be allowed, that doing all honour to heroes, above the rest of mankind, must needs conduce to the glory and advantage of a nation; but what shocks the imagination to reflect upon, is, that a polite people should think it reasonable, that an unhappy man, who was no way inferior to the victor, but by the chance of war, should be led like a slave at the wheel of his chariot. This behaviour to the conquered had no foundation in nature or policy, only to gratify the insolence of an haughty people, who triumphed over barbarous nations, by acting what was fit only for those very barbarians to practise. It seems wonderful, that they who were so refined as to take care that, to complete the honour done to the victorious officer, no power should be known above him in the empire, on the day of his triumph; but that the consuls themselves should be but guests at his table that evening; could not admit the man of chief note among his prisoners to be one of the company. This would have improved the gladness of the occasion, and the victor had made a much greater figure, in that no man appeared unhappy on this day, than because no other man appeared greater. *Potter's Græc. Antiq. Kennet's Rom. Ant. Dict. Trevoux.*

TRIUMVIR, one of three persons who govern absolutely, and with equal authority, in a state. It is chiefly applied to the Roman government: Cæsar, Pompey, and Crassus, were the first triumvirs who divided the government amongst them. There were also other officers, called triumvirs; as the triumviri or tresviri capitales, who were the keepers of the public gaol; they had the office of punishing malefactors; for which purpose they kept eight lictors under them. There were also triumviri monetales, the masters of the mint; whence the following mark is still extant on many ancient coins, III VIRI. Sometimes they were styled triumviri A. A. E. F. F. these letters standing for *auro, argento, ære, flando, feriando*. There were likewise nocturnal triumviri, instituted to prevent or extinguish fires in the night.

TRIUMVIRATE, an absolute government administered by three persons, with equal authority.

There were two famous triumvirates at Rome; Pompey, Cæsar, and Crassus, as mentioned in the preceding article, established the first; and Augustus, Marc Antony, and Lepidus, the second; which gave the last blow to the Roman republic; for Augustus having vanquished Lepidus and Antony, the triumvirate sunk into a monarchy.

TROCHAIC VERSE, in the Latin poetry, a kind of verse, so called because the trochees chiefly prevail, as the iambus does in the iambic. It generally consists of seven feet and a syllable; the odd feet, for the most part, consist of trochees, though a tribrachys is sometimes admitted, except in the seventh foot: these two feet are likewise used in the other places, as is also the spondeeus, dactylus, and anapæstus.

TROCHANTER, in anatomy, a name given to two apophyses, situated in the upper part of the thigh-bone:

they receive the tendons of most of the muscles of the thigh.

TROCHE, *Trochiscus*, in pharmacy, a sort of medicine, made of glutinous substances, into little cakes, and afterwards exsiccated. The four following rules are to be observed in making of them: 1. The ingredients are to be reduced to a powder. 2. If the mass proves so glutinous as to stick to the fingers in making up, the hands may be anointed with any convenient sweet or aromatic oil; or else sprinkled with powder of starch, or with that of liquorice. 3. In order to dry thoroughly the troches, put them on an inverted sieve, in a shady airy place, and frequently turn them. 4. The troches are to be kept in glass vessels, or in earthen ones well glazed. There are troches of various kinds, and for various intentions, as purgative, alterative, aperitive, corroborative, &c. The chief troches now in use are those of myrrh and liquorice, and those of the testaceous powders for the heart-burn.

TROCHEE, *Trocheus*, in the Greek and Latin poetry, a foot consisting of two syllables, the first long, and the second short, as in the words *musa* and *servat*.

TROCHILUS, in architecture, a name used by the antients for what the moderns call scotia.

TROCHITÆ, in natural history, a name given to the separate joints of the entrochus. See the article **ENTROCHUS**.

TROCHLEA, one of the mechanical powers, usually called a pulley. See **PULLEY**.

TROCHLEARES, in anatomy, a name given to the oblique muscles of the eye.

TROCHOID, in geometry, a curve more generally known by the name of cycloid.

TROCHUS, in natural history, the name given by authors to a genus of shells; some of the species of which resemble the figure of the trochus, or top which boys play with. As there are many species of this shell, however, which are flatted, and have nothing of this form, the whole series are much better named, by a denomination taken from the shape of the mouth, which is of an oval figure, and is alike in all these species, and different from all other shells. They are therefore aptly characterized by a late French writer under the name of *cochleæ ore depresso*.

TROGLODYTES, in the ancient geography, a people of Ethiopia, said to have lived in caves under ground. Pom. Mela gives a strange account of the Troglodytes: he says, they did not so properly speak as shriek, and that they lived on serpents.

TROJA, or **TROJAN GAMES**, were games said to be instituted by Ascanius, son of Æneas, and afterwards kept up by the Romans with great solemnity. They were celebrated by companies of boys, neatly dressed, and furnished with little arms and weapons, who mustered in the public Circus. They were chosen, for the most part, out of the noblest families of Rome, and the captain of them had the honourable title of *Princeps Juventutis*, being sometimes next heir to the empire, and seldom less than the son of a principal senator. A particular account of these games may be seen in the fifth Æneid of Virgil, beginning at verse 545.

TROIS-CINQUE, in French distillery, a term used to express their brandy when of a peculiar strength, consisting of five parts alcohol, and three parts phlegm.

The method of distilling the wines into brandy, in France, is exactly the same with that used with us to draw the spirit from our wash or fomented liquor of malt, treacle, sugar, or whatever other kind. They only observe more particularly to throw a little of the natural lee into the still, along with the wine; and the poorest wines are found to succeed best on the trial, making by much the finest brandies. We are apt to wonder, that we cannot from the wines of particular countries distil their particular brandies; but the whole mystery consists in this, that they do not send us over the same wines which they use in distilling, because these latter would not be liked as wines, nor would keep in the bringing over.

Sometimes, in Scotland, they meet with the poor and pricked wines, the same that the French distil their brandies

dies from; and from these they distil a spirit, not to be known from the brandy distilled in France.

The lee, which the French add in the distillation, gives the brandy that high flavour for which we so much esteem it; but they themselves like it much the worse for it. The French notion of a proof strength, determined by the chaplet or crown of bubbles, is the same with ours; and all their fine spirits are found of this strength.

But they have one particular expedient for those brandies which prove foul and seedy, or retain the taste of certain weeds which grow among the vines; they draw them over again, with a design to free them from that adventitious flavour. In this operation they always leave out the faints, or rather they change the receiver as soon as ever the stream comes proof; then mixing together all that run off before, they make a brandy stronger than the ordinary kind, and this is what they call *trois-cinque*.

The distillers in France scarce ever bring their brandies higher than this; for they have the art to persuade the foreign merchant, that the phlegm of French brandy is natural and essential to it: but the truth is, that the spirit alone contains the flavour and excellence of the brandy, and it might as well be reduced to half its bulk for exportation, and sent over in the state of alcohol, and then lowered with common water, to the proof strength.

The French use no art in colouring their *trois-cinque*, any more than their common proof-brandy, nor do they add any thing to give them an additional flavour; the thing which they principally value themselves upon, both in regard to brandies and wines, being to make them perfectly natural: so that all the colour we find in their brandies, is acquired from the cask, and the time they are left in it. This is often twelve or eighteen months, sometimes two or three years; in this time they acquire a brown colour, and lose their acrid taste.

The greatest adulteration of brandies is in England; the French have no temptation to do it, they having no cheaper spirit, since the prohibition of molasses in their country. The Dutch are in the same condition, having no molasses spirit; and only a very coarse and nauseous sugar-spirit, and yet a worse malt-spirit of their own manufacture; a single gallon of which would spoil a whole piece of brandy. The French brandy also, paying no duty in Holland, is as cheap, or nearly so, there, as in France itself. The duties being high upon brandy, it is greatly adulterated, and that with all sorts of spirits, &c. as malt, molasses, cyder, and sugar-spirits: and, when this is done in a dexterous and sparing manner, the cheat is not easily found out. *Shaw's Essay on Distillery*.

TROLLIUS, globe ranunculus, in botany, a genus of plants, the flower of which has no empalement; it has about fourteen oval petals, whose points meet together, with nine nectariums, which are narrow, plain, incurved, and umbilicated, perforated at their base, and a great number of bristly stamina, terminated by erect summits, with numerous germina sitting close like a column, having no styles, but are crowned by pointed stigmas. The germen afterward becomes so many capsules, collected into an oval head, each containing one seed.

There are two species of this plant enumerated by Mr. Miller. The first sort grows naturally in the northern counties in England, and in many parts of Wales. It has been found in great plenty growing in the park of Burrow-Hall, in Lancashire; it has a perennial, fibrous, black root, from which spring up many leaves, which resemble those of wolf-bane, cut into five segments almost to the bottom; the stalk rises near two feet high; it is smooth, hollow, and branches toward the top; each branch is terminated by one large yellow flower, shaped like those of crow-foot, which has no empalement, composed of several concave petals, whose points turn inward toward each other, covering the parts of generation, so are of a globular form; whence it had the name of globe ranunculus. It flowers the latter end of May and the beginning of June, and the seeds ripen in Au-

gust. This plant is frequently kept in gardens about London, and is easily propagated by parting of the roots; the best time for doing this is the latter end of September, when the leaves are beginning to decay. The roots should not be divided into small parts, if they are expected to flower strong the following year, and should be planted at a foot distance from each other; it requires a shady situation and a moist soil. The roots need not be removed or parted oftener than once in three years, unless there is a desire of increasing them.

The second sort grows naturally in Siberia, from whence it was brought to the imperial garden at Petersburg, and has been communicated since to several parts of Europe; this differs from the first in having larger leaves, which are of a lighter green colour; their segments are fewer and larger, resembling those of the yellow monkshood. The petals of the flower spread open, and do not converge at their points like those of the first sort. The flowers, stamina, and nectariums, are of an elegant saffron colour. It flowers in May.

This sort may be propagated and treated in the same way as the first; but it requires a moister soil, and should have a shady situation, but not under the drip of trees; it thrives best on a north border where the soil is loamy, but not too stiff. In such situations the plants will produce seeds in England; but if they are in a dry soil, or much exposed to the sun, they frequently die in summer. Mr. Miller says he has seen this sort in the most flourishing state, where the surface of the ground was covered with moss to keep it moist.

As the flowers of both these plants make a pretty appearance during their continuance, they deserve a place in every good garden for the sake of variety, especially as they will thrive in moist shady places where few better plants will live; and by thus suiting the plants to the different soils and situations of a garden, every part may be furnished with beauties, and a great variety may be preserved.

TRONAGE, an ancient customary toll, paid for weighing of wool. This word is particularly mentioned in a charter granted to the mayor and citizens of London; in which city there is an officer called *tronator*, whose business it is to weigh the wool that is brought thither.

TRONCONNIE, in heraldry, denotes a cross, or other thing, cut in pieces and dismembered, yet so as all the pieces keep up the form of a cross, though set at a small distance from one another.

TRONE-WEIGHT, the same with what we now call troy-weight.

TROOP, a small body of horse or dragoons, about fifty or sixty, sometimes more, sometimes less; commanded by a captain. Each troop, besides a captain, has a lieutenant, cornet, quarter-master, and three corporals, who are the lowest officers of a troop.

TROPEOLUM, the Indian Cress, in botany, a genus of plants, the flower of which consists of five roundish petals inserted into the divisions of the cup; the two upper petals are sessile; the three others have very long and barbated unguis; the fruit consists of three convex capsules, sulcated and striated on one side, and angular on the other; the seeds are three, gibbous on one side, and angulated on the other, but upon the whole somewhat roundish, and striated deeply.

There are two sorts of this plant, the first growing naturally in Peru, and the second about Lima. The first sort is less common at present in the English gardens than the second, though it was formerly more so; the flowers of the latter being larger make a finer appearance, for which it is preferred; they are both esteemed annual plants, though they may be continued through the winter, if they are kept in pots, and sheltered in a good green-house; the former produce no seeds, and are therefore propagated by cuttings; but the latter ripen their seeds constantly every year, and the plants are generally raised from them. These may be sown in April in the places where they are to remain, which should be where their stalks may have support; for they will climb six or eight feet high, when they are trained up, and then their

their flowers will make a good appearance; but when they trail upon the ground, they will spread over the neighbouring plants, and become unsightly.

The flowers of these plants are frequently eaten in fallads; they have a warm taste like the garden cress, and are esteemed very wholesome; they are likewise used for garnishing dishes. The seeds are pickled, and by some are preferred to most kinds of pickles for sauce.

TROPE, in rhetoric, a kind of figure of speech, whereby a word is removed from its first and natural signification, and applied with advantage to another thing, which it does not originally mean; but only stands for it, as it has a relation to, or connection with it: as in this sentence, "God is my rock." Here the trope lies in the word *rock*, which being firm and immovable, excites in our minds the notion of God's unfailing power, and the steady support which good men receive from their dependence upon him.

Tropes are used for the sake of an agreeable variety; they divert the mind, and revive attention, when it begins to flag and be weary. In many cases there is an absolute necessity for the writer or speaker to repeat the same thing several times; therefore, to prevent the tiresome repetition of the same words, he carefully diversifies his expressions, and judiciously intermixes plain and figurative language. Tropes add a wonderful ornament and strength to a discourse, and often give the mind a brighter and stronger idea of a thing, than proper words: Thus Virgil calling the two Scipios the "Thunder-bolts of war," represents the rapid speed and victorious progress of their arms more emphatically, than all the plain terms of the Roman language could have done. In order to make use of tropes seasonably, and with advantage, the following rules should be observed: 1. Being sparing and cautious in the use of them, and omit them when they are not either as plain as proper words, or more expressive: tropes are the riches of a language, and it will be an imputation upon a man to lavish them away without discretion. 2. Care must be taken, that tropes hold a proportion to the ideas intended to be raised by them; there ought to be an easy and unforced relation betwixt the trope and the proper word it is put for, or the thing intended to be expressed by it: when there is not this suitableness and relation, the expression at best will not only be harsh and unpleasant, but often ridiculous and barbarous. In order to preserve this relation, a trope ought not to express more or less than the thing requires; and things capable of heightening or ornament ought not to be debased nor vilified by low expressions; nor small matters over-magnified by pompous and swelling words. 3. A trope ought to be obvious and intelligible, and therefore must not be fetched from things too remote, so as to require much reading and learning to apprehend it.

TROPHY, *Trophæum*, among the ancients, a pile or heap of arms of a vanquished enemy, raised by the conqueror in the most eminent part of the field of battle.

The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed, was generally mentioned, as was that also of the conqueror. The spoils were at first hung upon the trunk of a tree; but instead of trees, succeeding ages erected pillars of stone, or brass, to continue the memory of their victories. To demolish a trophy was looked upon as a kind of sacrilege, because they were all consecrated to some deity.

The representation of a trophy is often to be met with on medals of the Roman emperors, struck on occasion of victories; wherein, besides arms and spoils, are frequently seen one or two captives by the sides of the trophy.

In architecture trophy signifies an ornament which represents the trunk of a tree, charged or encompassed all round about with arms or military weapons, both offensive and defensive.

TROPHY MONEY, denotes certain money annually raised in the several counties of the kingdom, towards providing harness, and maintaining the militia.

TROPICS, in astronomy and geography, are two circles supposed to be drawn on each side of the equi-

noctial, and parallel thereto. That on the north-side of the line is called the tropic of cancer, and the southern tropic has the name of capricorn, as passing through the beginning of those signs. They are distant from the equinoctial $23^{\circ} 29'$. Two circles drawn at the same distance from the equator on the terrestrial globe, have the same names in geography, and they include that space or part of the sphere, which is called the torrid zone, because the sun is, at one time or other, perpendicular over every part of that zone, and extremely torridifies or heats it. See **ZONE**.

TROT, in the manege, one of the natural paces of a horse performed with two legs in the air, and two on the ground at the same time cross-wise, like St. Andrew's cross, and continuing so alternately to raise the hind-leg of the one side, and the fore-leg of the other side at once, leaving the other hind and fore-leg upon the ground, till the former come down. In this motion, the nearer the horse takes his limbs from the ground, the opener, the evener, and shorter his trot will be. If he takes up his feet slovenly, it is a sign of stumbling and lameness; if he treads narrow or cross, it betokens interfering or failing; if he treads long it shews over reaching; if he steps uneven, it bespeaks toil and weariness.

TROVER, in law, an action which a man hath against one that, having found any of his goods, refuseth to deliver them upon demand.

TROUGH of the Sea, is the hollow or cavity made between two waves or billows in a rolling sea.

TROUSSEQUIN, in the manege, an arch of wood raised above the hinder bow of a great saddle, in order to keep the bolsters firm.

TROUT, a very valuable river-fish, the distinguishing characters of which are these: its body is long; its head short and roundish; the end of its nose or snout obtuse and blunt; its tail is very broad; its mouth large; and each jaw furnished with one row of sharp teeth; and in its palate there are three parcels of teeth, each of an oblong figure in the congeries, and all meeting in an angle near the end of the nose; and the tongue has six, eight, or ten teeth also on it, and its sides are beautifully variegated with red spots.

This delicious fish is observed to come in and go out of season with the stag, and buck; the time of its spawning is remarkable: most other fish do this in warm weather, but the Trout in October or November. Among the several kinds of Trout, the red and the yellow are the best for the table; and, in the same species, the female has always the preference to the male; the head of the female is smaller, and the body deeper than in the male. They are known to be in season by the bright colour of their spots, and by the largeness and thickness of their backs; which last is a general rule in regard to all fish, to know when they are in season.

In winter the trout is sick, lean and unwholesome, and very often is lousy. The louse, as it is called, of the trout, is a small worm with a large head, which sticks very fast to the sides of the fish; they live upon the juices of the fish all the time of the cold weather, while he is poor and lies quiet in the deep waters; but when the warm weather in the spring comes on, and the fish leaves his lazy life at the bottom, and comes up to the shallow gravelly places, where the stream is swift, he soon shakes them off.

The trout, at his first coming into the shallow waters, may be seen to rub his body continually upon the sharp gravel at the bottom; it is by this means he gets off these worms or lice, as they are called. From this time he begins to feed on flies; but, in May, the peculiar fly that he is fond of is produced, and, after feeding that whole month on this insect, the flesh of the fish becomes more red and firm, and its highest season begins.

The general baits for a trout, are a worm, a minnow, or a fly, whether natural or artificial: among worms, there are several kinds which this fish is fond of; such are the earth-worm and dung worm in particular; the lob-worm and branding-worm are also esteemed: but the best of all is the squirrel-tail-worm, which has a streak down the back, a red head, and a broad tail.

The

The brandling is commonly found in an old dung-hill, or under cow-dung, or else among tanners bark; the others are found in the earth, and under large stones or stumps of trees: whatever worm is used, the longer it is kept to scower first, the better the trout will take it: they are to be kept in an earthen pot among moss, which is to be shifted once in three or four days, or oftener, if the weather be very hot.

To take the trout with a ground-bait, the angler should have a light taper rod, with a tender hazel top; and may angle with a single hair of three links, the one tied to the other, for the bottom of the line; and a line of three-haired links for the upper part: with this sort of tackle, if the sportsman have room enough, he will take the largest trout in the river. Some fish with three-haired links at the bottom of the line, but there is very little sport to be expected this way, for the trout is very suspicious, and very quick-sighted. The angler must always keep out of sight, and the point of the rod must be down the stream. The season for fishing for the trout with a ground-bait begins in March, and the mornings and evenings in general are the best times; but, if the weather be cloudy, the sport may be followed all day long: there must be a plummet at ten inches from the hook, which the angler must feel always touching the ground, and this must be heavier, the swifter the stream is. The common worm is a good bait.

The minnow is a very good bait for the trout, and with this the tackle need not be so slight, for the trout will make at this bait with less consideration, and seize it as soon as it comes in sight; the upper part of the line with this bait may be of three silks and three hairs for the upper part, and two silks and two hairs for the lower; and the hook may be moderately large. The whitest minnows and those of the middle size are the best bait for the trout, and they should be so fixed on the hook, as to turn round when they are drawn up against the stream.

The best way of baiting this fish is to put the hook in at the mouth and out at the gills, then drawing it through about three inches, to put it again into its mouth, and let the point and beard come out at the tail, and then to tie the hook and his tail with a fine white thread, letting the body of the minnow be almost straight down to the hook; by this means it will turn, as it is pulled against the stream: and, the more and quicker it turns, the better: for want of a minnow, a small loach or a stickleback will serve.

The most agreeable manner of fishing for trout is, however, with the fly, when the sportsman has found the true method of doing it; the rod in this case must be light and pliable, and the line long and fine; if one hair be strong enough, as it may be made, by proper skill in the angler, there will be more fish caught, than where a thicker line is used; and the fly-fisher should have the wind at his back, and the sun before him.

TRUCE, in the art of war, denotes a suspension of arms, or a cessation of hostilities between two armies, in order to settle articles of peace, bury the dead, or the like.

TRUCHMAN, DRAGOMAN, or DROGMAN, in the countries of the Levant, signifies an interpreter.

TRUCKS, among gunners, round pieces of wood, in form of wheels, fixed on the axle-trees of carriages, to move the ordnance at sea, and sometimes also at land.

TRUE, something agreeable to the reality of things, or to truth.

TRUE place of a planet, or star, in astronomy, is a point of the heavens, shewn or pointed out by a right line, drawn from the center of the earth through the center of the planet or star.

TRUFFLES, *Tubera terræ*, in natural history, a kind of subterraneous vegetable production, not unlike mushrooms.

All substances which appear to vegetate may, generally speaking, be divided into two classes; such as have all the characteristics of plants, and such as want some of these characteristics. Among those of the latter kind, some have no appearance of flowers, as the fig-tree, whose flower is thought to be wrapped up in its fruit; others want the appearance both of flowers and seeds, such as

the most part of the sea-plants, whose seeds are suspected to be concealed in particular vesicles destined for that purpose; others have only leaves without stalks, such as liverwort, sea-lettice, and nostoch; others have stalks without leaves, such as the euphorbium, the horse-tail, the sea-oak, corals, and the most part of stony plants. Lastly, others have scarcely any appearance of plants, not having visibly either leaves, flowers, or seeds. Of this kind are most mushrooms, sponges, morellæ, and especially truffles, which are likewise without roots. Botanists have only ranked them among the class of plants, because they are observed to grow and multiply, not doubting, but they contained the essential, though they were destitute of the apparent parts of plants; as insects have the essential parts of an animal, though their outward form should have a different appearance. Having made some observations on the nostoch, I was led to examine the truffle also, which is still more singular, and, for aught I know, has as yet had nothing positive advanced concerning it; I shall therefore give an account of the observations I have made upon it, and the uncommon manner of its vegetation.

This sort of plant is only a fleshy tubercle covered with a hard sort of crust, rough, and somewhat regularly furrowed, on the surface almost like the cypress-nut. It does not rise above the surface of the earth, but lies concealed about half a foot below it. Great numbers of them are found in the same place, of different sizes. Some of them are now and then found of a pound weight, or even a pound and a quarter; these last are but rare, and Pliny only mentions their being of a pound weight.

It is certain, however, that some of them are very large; they grow in different countries, and, in Pliny's time, the most valuable were brought from Africa. They are now found in Europe, in Brandenburg, and several other parts of Germany, and are very common in Italy, Provence, Dauphiné, Languedoc, Anjou, and Perigord. They grow also in Burgundy, and some of them are found about Paris; it is observed, that they are ordinarily found in fields, that they are uncultivated, of a reddish-coloured earth, and sandy, but somewhat rich. They grow at the feet, and under the shades of trees, sometimes about the roots of stones, and sometimes in clear earth. Their favourite trees are either the white or green oak, as the elm is that of the morellæ. They begin to be found when warm weather first succeeds the cold, sooner or later, as the season is more or less mild; for they have sometimes been very rare after hard winters. At first they appear only like little round pease, red without, and white within. These pease grow larger by degrees; from that time they take out of the ground what they commonly call white truffles; these are of themselves insipid, and people dry them as an ingredient for ragouts, because they keep better, when dried, than marbled ones do. It is a common opinion, that truffles which have once been removed from their places, are never after capable of being nourished, even when put in some earth from which they were originally taken: but if one leave them there for a certain season, without disturbing them, they grow insensibly larger, their bark becomes black, rough, and unequal, though they always retain their whiteness within. Hitherto, they have very little smell or taste, and can only be used in ragouts. These are always called the first white truffles; and are not to be made a different species from the marbled or black ones gathered in the end of autumn, and even in the winter after the frosts are begun; for, in my opinion, they are only the same, arrived at different degrees of maturity. I look upon the white truffles, in its first state, as a plant which is at one and the same time, root, stalk, and flower, whose parenchyma swells every way, and whose parts are insensibly unfolded: in proportion as the truffle swells, its bark becomes hard and furrowed in different places, that so it may convey the more nourishment to the grosser mass: then the truffle changes its colour, and, instead of white, it insensibly becomes marbled with greyish streaks, and that which was formerly white, now looks like a congeries of small pipes, which spread themselves in the heart of the truffle, and terminate in the furrows of the bark.

The greyish substance which is wrapped up amidst these canals, when viewed with a microscope, appears to be a transparent parenchyma, composed of vessels, or little bladders: in the middle of this substance appear black round points distinct from one another, which have all the appearance of seeds nourished in that substance, whose colour they have darkened, and in which there remains nothing white except the vessels and some capillæ. I look upon that white substance as hollow pipes, because I always see them terminate in the bark.

When the truffles are arrived at this degree of maturity, they are of a very good smell and taste: the heat and rain, during the month of August, forward their ripening very fast, which may possibly be the reason why some authors have said that storms and thunder first produced them. The truth is, good truffles are not dug but from the month of October to the end of December; and sometimes to the end of February and March, when they are ever at that time marbled; whereas those gathered from the month of April till July and August, are only white. If the people neglect to gather the truffles when arrived at a due degree of maturity, they rot; and then we may observe the re-production of the truffle, because, after some time, we see several bunches of other young truffles filling up the places of the rotten ones. These young truffles are nourished till the first colds come on, and if the frosts are not intense, they get over the winter, and furnish us betimes with the fresh green truffles.

The excessive cold in the year 1709 is an additional proof of what I advance, since truffles were not found till the autumn of that year; the most forward ones, which should have appeared in the spring, having perished by the rigour of the season, whereas they were very common the foregoing year.

We observe neither hairs nor filaments of roots at the truffles, when taken out of the earth, with which they are covered in such a manner as to leave the traces of their bark imprinted in it, without appearing to have any other communication with it. They are subject, like other roots, to be eat into by worms. The worm which preys upon the truffle is white, small, and different from that which is hatched by its corruption: afterwards, this worm forms a kind of bean, shut up in a very slender covering of a white kind of silk; from which, some time after, comes forth a bluish violet coloured fly, which makes its way, from the truffle, thro' the furrows or clefts observed in it. These flies are infallible signs that there are truffles to be found near the places where they are observed.

If a dressed truffle has been pierced by a worm, it may be discovered by its being bitter to the taste; and, by a little attention, one may observe the place where the hole is, to be blacker than the rest, and that the bitterness is caused by it, since the rest of the truffle tastes well. Upon laying open the place where the hole is, one may easily discover the nest of the worm, and a place round it free from marbling, of a different colour from the rest of the truffle, and resembling that of rotten wood. Upon viewing the surface of truffles with a microscope, I found that certain white specks, which I saw there, were so many small insects which preyed upon them. They follow the furrows of the bark, that they may the more commodiously suck their nourishment. These insects are white, transparent, and of a round figure, almost like mites. They have only four feet, a small head, and creep pretty fast. These insects are nourished by the nutritive juice of the truffle; for I have found some of them lodged in the same cell which had formerly been inhabited by the worm: they were become, though transparent, of a coffee-colour, like the place where the worm had nestled. It is to be observed, that the earth which produces truffles, bears no other plants upon it; for the truffle absorbs its nutritive juice, or rather, by its smell, destroys, or prevents, the springing of other herbs. This reason appears to me so much the more probable, because the earth wherein they grow smells perfectly like them. The peasants, in some parts, receive profits so considerable from the sale of truffles, as to render them very industrious in discover-

ing the grounds where they grow, so that they are become now very skilful at it. They know the extent of the ground where the truffles are by its bearing nothing, and being void of all herbs. In the second place, according to the quality of the earth, if the ground abounds with truffles, it is chapped in several places. They also know it by its being more light than other earth, by these little, bluish, violet-coloured flies I have mentioned, and by another sort of flies which are large, black, long, and different from those produced from the worm, but which are ingendered by the corruption of the truffle, and like those which are hatched in every other corrupted matter. There is a dexterity in digging truffles, without cutting them, if they are large. The peasants have a kind of planting-stick for digging them. In other parts, they do not trouble themselves with searching for them, but have recourse to another method mentioned by Pliny, and other authors. Swine are known to be very greedy of truffles; they, themselves, make use of one of these animals, which they train up to discover and dig them; but there is a necessity for being very quick in taking the truffles from them, and giving them something in their stead, lest they should be discouraged, and give over a pursuit from which they receive no advantage; and in Montferrat they have dogs trained up for this very purpose.

As to the virtues of truffles, the common opinion is, that they are hot. Galen, however, according to Matthiolus, looks upon them as indifferent, and the basis of all other seasoning; and indeed it is to this purpose that they are used in all ragouts. Avicenna speaks of them in a manner quite different, and says, they engender thick humours more than any other food; that they are hard of digestion, heavy on the stomach, and, when much used, have a tendency to bring on an apoplexy and palsy. These two authors may be reconciled, if we consider two qualities in the truffle, which are capable of producing two different effects: first, they may prove hot of themselves, by emitting their volatile salts into the stomach; or by being mixed with salt, pepper, and other spices, which they drink up like a sponge. In the second place, they may prove of hard digestion, when eaten immoderately by a person of a weak stomach: in which case they produce bad effects, stagnate, and form themselves into a glaucous substance, which disorders the stomach, and which may be occasioned by the cold quality ascribed to them by Galen. As a proof that the truffle is of hard digestion, it has this in common with other fruits, that it grows hard in spirit of wine, and is with difficulty dissolved in water. *Geoffroy, in the Memoires de l'Acad. Roy. des Scienc. A. 1711.*

TRUMPET, a musical instrument, the most noble of all portable ones of the wind kind, used chiefly in war among the cavalry, to direct them in the service.

Marine TRUMPET, is a musical instrument consisting of three tables, which form its triangular body. It has a very long neck, with one single string, very thick, mounted on a bridge, which is firm on one side, but tremulous on the other. It is struck by a bow with one hand, and with the other the string is pressed, or stopped, on the neck by the thumb. It is the trembling of the bridge, when struck, that makes it imitate the sound of a trumpet; which it does to that perfection, that it is scarce possible to distinguish the one from the other: and this is what has given it the denomination of marine trumpet; though, in propriety, it is a kind of monochord.

Harmonical TRUMPET, an instrument that imitates the sound of a trumpet; which it resembles in every thing, excepting that it is longer, and consists of more branches: it is generally called sackbut.

Speaking TRUMPET, is a tube from six to fifteen feet long, made of tin, perfectly straight, and with a very large aperture; the mouth-piece being big enough to receive both lips.

The speaking trumpet, or stentorophonic tube, as some call it, is used for magnifying of sound, particularly that of speech, and thus causing it to be heard at a great distance. How it does this will be easy to understand from the structure thereof, thus illustrated by the ingenious

ingenious Mr. Martin: let ABC (plate CXXXII. fig. 20.) be the tube, BD the axis, and B the mouth-piece for conveying the voice to the tube.

Then it is evident, when a person speaks at B, in the trumpet, the whole force of his voice is spent upon the air contained in the tube, which will be agitated through the whole length of the tube; and by various reflections from the side of the tube to the axis, the air along the middle part of the tube will be greatly condensed, and its momentum proportionably increased; so that, when it comes to agitate the air at the orifice of the tube AC, its force will be as much greater than what it would have been without the tube, as the surface of a sphere, whose radius is equal to the length of the tube, is greater than the surface of the segment of such a sphere, whose base is the orifice of the tube. See the article SOUND.

For a person speaking at B, without the tube, will have the force of his voice spent in exciting concentric superficies of air all around the point B; and, when those superficies or pulses of air are diffused as far as D, every way, it is plain the force of the voice will be diffused through the whole superficies of a sphere whose radius is BD; but in the trumpet it will be so confined, that, at its exit, it will be only diffused through so much of that spherical surface of air, as corresponds to the orifice of the tube. But, since the force is given, its intensity will be always inversely, as the number of particles it has to move; and therefore, in the tube, it will be to that without, as the superficies of such a sphere to the area of the large end of the tube, nearly.

To make this matter yet plainer by calculation, let BD = 5 feet, then will the diameter of the sphere DE = 10 feet, the square of which is 100, which, multiplied by 0,7854, gives 78,54 square feet for the area of a great circle AHEFC.

And, therefore, four times that area, viz. $4 \times 78,54 = 314,16$ = square feet in the superficies of the aerial sphere. If now the diameter AC, of the end of a trumpet, be one foot, its area will be 0,7854; but $78,54 : 314,16 :: 1 : 400$, therefore the air at the distance of BD, will be agitated by means of the trumpet, with a force 400 times greater than by the bare voice alone.

Again, it is farther evident how instruments of this form assist the hearing greatly; for the weak and languid pulses of the air being received by the large end of the tube, and greatly multiplied and condensed by the tremulous motion of the parts of the tube, and air agitated by them, are conveyed to the ear by the small end, and strike it with an impetus as much greater than they would have done without it, as the area at the small end at B, is less than the area of the large end AC. From what has been said, it is evident the effect of the tube in magnifying sound, either for speaking or hearing, depends chiefly upon the length of the tube. But yet some advantage may be derived from the particular shape thereof. Some very eminent philosophers have proposed the figure which is made by the revolution of a parabola about its axis, as the best of any, where the mouth-piece of the parabola, and, consequently, the sonorous rays, will be reflected parallel to the axis of the tube.

But this parallel reflection seems no way essential to the magnifying of sound; on the contrary, it appears rather to hinder such an effect, by preventing the infinite number of reflections and reciprocations of sound; in which, according to Sir Isaac Newton, its augmentation doth principally consist. For all reciprocal motion, in every return, is augmented by its generating cause, which is here the tremulous motions of the parts of the tube. Therefore in every repercussion from the sides of the tube, the agitations and pulses of confined air must necessarily be increased; and consequently, this augmentation of the impetus of the pulses must be proportional to the number of such repercussions; and, therefore, to the length of the tube, and to such a figure as is most productive of them. Whence it appears, that the parabolic trumpet is, of all others, the most unfit for this purpose, instead of being the best.

But there is one thing more which contributes to the augmenting of these agitations of air in the tube, and

that is the proportion which the several portions of air bear to each other, when divided by transverse sections, at very small, but equal distances, from one end of the tube to the other. Thus, let those several divisions be made at the points, a, b, c, d, e , &c. (fig. 21.) in which let the right lines ak, bl, cm, dn , &c. be taken in geometrical proportion. Then will the portions of air contained between B and a , a and b , b and c , c and d , &c. be very nearly in the same proportion, as being in the same ratio with their bases, when the points of division are indefinitely near together.

But when any quantity of motion is communicated to a series of elastic bodies, it will receive the greatest augmentation when those bodies are in geometrical proportion. Therefore, since the force of the voice is impressed upon, and gradually propagated through, a series of elastic portions of air in a geometrical ratio to each other, it shall receive the greatest augmentation possible.

Now, since by construction it is $Ba = ab = bc = cd$, &c. and also $ak : bl :: bl : cm :: cm : dn$, and so on; therefore, the points $k, l, m, n, o, p, q, r, s$, A, will, in this case, form that curve line, which is called the logarithmic curve; consequently, a trumpet, formed by the revolution of this curve about its axis, will augment the sound in a greater degree than any other figured tube whatever.

Listening, or Hearing TRUMPET, an instrument invented by Joseph Landini, to assist the ear in hearing of persons who speak at a great distance, without the assistance of any speaking trumpet.

TRUMPET-FLOWER, *Bignonia*, in botany. See the article BIGNONIA.

TRUMPET-SHELL, in natural history, the English name of the buccinum of authors. See the article BUCINUM.

The family of the buccina, when examined ever so strictly, is very large; but, according to the general custom of authors, of confounding together several genera under the name, it is usually made to appear much larger than it really is. Lister has made it comprehend a vast number of shells, by confounding with it the families of the murex and purpura.

It is not indeed peculiar to this author to have confounded these genera; those who went before him have done the same: and Pliny has comprised the buccinum, murex, and purpura, under the general name ceryx.

To avoid the general confusion which arises from not distinguishing the families of the buccinum, murex, purpura, and vis, or screw-shell, it will be proper to observe, that there are regular characters which distinguish them all one from another; the characters are these:

The buccinum differs from the purpura, in that it has a very long mouth of an oval figure, and has an elevated head; whereas the purpura has a round mouth, and a head somewhat flattened. The tail of the purpura is also usually furrowed, and is shorter than that of the buccinum.

The buccinum differs also from the murex in having a longer tail, by the smoothness and variety of colours of its coat, and by having a larger mouth less furnished with teeth; the murex having a smaller and longer shaped mouth, its surface covered with points or spires, and several teeth.

It is easier to distinguish the buccinum from the screw-shell, as this is always more long and slender than the buccinum; it has also a flat mouth, and has rarely any tail. These are all very large families in nature, and it is highly necessary for the naturalists to be well acquainted with them. The most singular species of the buccinum class is one that hath its mouth turned the contrary way to all other shells: this has been thence called by authors the unique and the sans pareil. Aldrovand is of opinion, that the buccina may be ranked among the bivalve shells; because they have an operculum or shelly substance fixed to the end of their body, which occasionally stops up the aperture of the mouth; but if this were a sufficient reason, we should have many more genera to add to the bivalves, particularly the snails of several kinds.

The buccina generate in warm months, and some species

species of them have been frequently remaining in pairs together, upon the rocks, deserted by the tide on that occasion. These have been thence supposed to be of a different genus, and have been called *buccina littoralis*; they are usually found in copulation early in the morning.

TRUMPETER, in zoology, a name given in England to a particular species of pigeon, called by Moore the *columba tibicen*.

This species is of the middle size of the common pigeon, and made considerably like it; but it is pearly-eyed; is of a mottled black, and is feathered down to the legs and feet, and is turn-crowned like the nun, and some other species; sometimes like the finnikin, but much larger: this seems to be the best sort, as being the most melodious. The best character, to know them by, is a tuft of feathers growing at the root of the beak; and, the larger this tuft is, the more they are esteemed. The reason of their name is, that they imitate in their cooing the sound of the trumpet; but, to be often entertained with their melody, it is necessary to feed them frequently with hemp-seed. *Moore's Columbarium*.

Feast of TRUMPETS, an annual festival of the Jews, expressly enjoined by the law of Moses, and observed upon the first day of the seventh month, called Tisri, which was the beginning of the civil year.

This festival is expressly called a sabbath, and was a very solemn day, on which no servile work was to be done; only provision made for their meals, which were usually very plentiful at this time. Among other dishes, they served up a ram's head, in memory of that ram which was sacrificed in the room of Isaac; which they fancy was done upon this day. All the festivals of the Jews, it is true, were introduced by the sound of trumpets: but this was attended with more than usual solemnity; for they began to blow at sun-rising, and continued till sun-set. And whereas, in other places, the beginning of the year was sounded with a trumpet of ram's or sheep's horn, at the temple they used two silver trumpets, and the Levites upon that day sung the eighty-first psalm.

This festival is called "A memorial of blowing of trumpets:" but it is not so easy to determine what this blowing of trumpets was a memorial of. Maimonides will have it to be instituted, to awaken the people out of sleep, and call them to repentance; being intended to put them in mind of the great day of expiation, which followed nine days after. Basil imagined, that by these soundings the people were put in mind of that day, wherein they received the law from Sinai with blowing of trumpets. Others think it more probable, that since all nations made great shouting, rejoicing, and feasting, in the beginning of the year, at the first new-moon, in hopes that the rest of the year by this means would prove more prosperous, God was pleased to ordain this festival among his people, in honour of himself, upon the day of the first new-moon, to preserve them from idolatry, and to make them sensible, that he alone gave them good years. Others again imagine, that God marked this month with a peculiar honour, because it was the seventh; that, as every seventh day was a sabbath, and every seventh year the land rested, so every seventh month of every year should be a kind of sabbatical month: and upon that account the people might be awakened by this blowing of trumpets, to observe this festival with the proper ceremonies. Lastly, others explain this blowing of trumpets to be a memorial of the creation of the world, which was in autumn. Upon this account it was that they antiently began their years at this time, as the eastern people do at this day. By this means they also confessed the divine goodness in blessing the year past, and bringing them to the beginning of a new year, which they prayed that God would make happy and propitious to them.

The sacrifices to be offered upon this day were, the daily burnt-sacrifice; then the sacrifices appointed for the first day of every month; then the proper sacrifices, over and above the rest, appointed for the first day of the seventh month, which consisted of a bullock, a ram, and seven lambs for burnt-offerings, and a goat for a sin-offering.

The modern Jews, upon this festival, make better cheer than ordinary, and sound the trumpet thirty times successively. Eight days before the feast, they apply themselves to works of mortification and penance; and, the evening before, many of them receive thirty-nine blows with a whip, by way of discipline. This they do upon an opinion, that on this day God judges of the actions of the foregoing year, and disposes of the events of the year following. They use to each other this form of salutation, "May you be written in a good year;" to which the answer is, "And you also." Some go to the synagogue clothed in white, as a token of purity and penance; and among the Germans, some wear the habit appointed for their burial, as a sign of mortification. Others plunge themselves in cold water, and, as they sink, beat their breasts, and confess their sins.

TRUNCATED, in general, an appellation given to such things as have, or seem to have, their points cut off: thus we say, a truncated cone, pyramid, leaf, &c.

TRUNCHEON, a short staff, or battoon, used by kings, generals, and great officers, as a mark of their command.

TRUNDLE, a sort of carriage with low wheels, whereon heavy and cumbersome burdens are drawn.

TRUNDLE-SHOT. See the article **SHOT**.

TRUNK, *Truncus*, among botanists, denotes the stem, or body, of a tree; or, that part between the ground and the place where it divides into branches.

In anatomy, trunk is used for the busto of a human body, exclusive of the head and limbs, comprehending the abdomen and thorax. See the article **ABDOMEN** and **THORAX**.

Trunk is also used for the main body of an artery, or vein, in contradistinction to the branches and ramifications thereof.

Trunk-roots of a plant, are little roots which grow out of the trunks of plants.

These are of two kinds: 1. Such as vegetate by a direct descent, the place of their eruption being sometimes all along the trunk, as in mints, &c. and sometimes only in the utmost point, as in brambles.

2. Such as neither ascend nor descend, but shoot forth at right angles to the trunk; which therefore, though as to their office they are true roots, yet, as to their nature, are a medium between a trunk and a root.

TRUNNIONS, or **TRUNIONS** of a piece of Ordnance, are those knobs or bunches of the gun's metal, which bear her up on the cheeks of the carriage: and hence the trunnion-ring is the ring about a cannon, next before the trunnions.

TRUSS, *Trussa*, a bundle, or certain quantity of hay, straw, &c.

A truss of hay is to contain fifty-six pounds, or half an hundred weight; thirty-six trusses make a load. In June and August the truss is to weigh sixty pounds, on forfeiture of eighteen shillings per truss.

A truss of forage is as much as a trooper can carry on his horse's crupper.

TRUSS of Flowers, is used, by florists, to signify many flowers growing together on the head of a stalk, as in the cowslip, auricula, &c.

TRUSS is also used for a sort of bandage or ligature, made of steel, or the like matter, wherewith to keep up the parts, in those who have hernias or ruptures.

In plate CXXXII. *fig. 22. &c.* are represented various kinds of trusses, to compress the parts, and prevent a relapse of the intestine after the rupture has been cured. Some of these, as *fig. 24, 29, and 30*, are made of calicoe, for infants; or of leather, for adults. Others, as *fig. 22, 24, 25, and 32*, are made of steel covered with leather. Some are made of steel-plates, joined by hinges, so as to be flexible and more easy, as in *fig. 32*. Some again are designed for ruptures on both sides; as *fig. 25. and 26*. Some are for ruptures on the right side, as *fig. 23, and 24*: others for the left; as *22, 30, 31, and 32*. Some, again, are fastened to the body by tagged-laces; as *fig. 26, 27, and 30*: others by straps and buckles; as *fig. 23, 26, and 30*: others by hooks and eyes, or hooks and straps; as *fig. 22, 24, and 25*: and others again by different contrivances; as in *fig. 28, and 29*.

In all these trusses, A denotes the bolster or compress, which is applied to the ring of the abdominal muscles, after the rupture has been reduced: B B the girdle or belt of the truss, to be fastened round the body, either with strings C C, passed through the holes D D; or by straps and buckles, as in *fig.* 23, and 31, marked E E: or with hooks, as in *fig.* 22, 24, 25, and 32, marked a a. In many of these trusses there is a depending girt, besides that which passes round the body, which is to be passed between the legs of women, and fastened to the opposite part of the belt: as F F in *fig.* 22, 24, 27, 28, 29, 30, and 31. In *fig.* 27, is shewn the bolster a; and in *fig.* 28, may be seen a wooden bolster c d, e e being the button by which it is fastened to the truss, and d the convex part by which it is applied to the rupture.

There are a multitude of other trusses, of various forms, contrived by those who make it their business; but we have here given figures of the best of them.

TRUSSES, in a ship, are ropes made fast to the parrels of a yard, either to bind the yard to the mast when the ship rolls, or to hale down the yards in a storm, &c.

TRUSSING, in falconry, is a hawk's raising any fowl, or prey, aloft; first soaring up, and then descending with it to the ground.

TRUST, in law, signifies, in general, that confidence which one person reposes in another; and in case of non-performance, or breach of this trust, the remedy is by bill in equity, as the common-law usually takes no notice of trusts.

Conveyances made in the way of trust, which were formerly invented to evade the statute of uses, are not so much favoured as plain and direct deeds. All declarations of trusts of lands, &c. are to be in writing, and signed by the parties. It has been decreed in Chancery, that a fine and recovery of a cestuiqui trust shall bar and transfer the estate, as they should an estate at law, where the same were levied or suffered on good consideration. And there is a statute whereby an infant seized of an estate in fee in trust, is enabled to make any conveyance thereof, by order of the court of Chancery.

TRUSTEE, one who has an estate, or money, put or trusted in his hands, for the use of another.

Where two or more persons are appointed trustees, if one of them only receives all or the greatest part of the profits of the lands, &c. and is in arrear, and unable to satisfy the person to whom he is seized in trust, the other, in that case, shall not be answerable for more than comes to his hands.

TRUTH, *Veritas*, a term used in opposition to falsehood, and applied to propositions which answer, or accord, to the nature and reality of the thing of which something is affirmed or denied.

Truth, according to Mr. Locke, consists in the joining or separating of signs, as the things signified by them do agree or disagree one with another. Now the joining or separating of signs is what we call making of propositions. Truth then, properly relates only to propositions, of which there are two sorts, mental and verbal; as there are two sorts of signs commonly made use of, viz. ideas and words.

Mental propositions are those wherein the ideas in our understanding are put together, or separated, by the mind perceiving or judging of their agreement or disagreement.

Verbal propositions are words put together, or separated, in affirmative or negative sentences: so that a proposition consists in joining or separating of signs; and truth consists in putting together, or separating those signs, according as the things they stand for agree or disagree.

Moral TRUTH consists in speaking things according to the persuasion of our minds, and is called also veracity.

Metaphysical, or Transcendental TRUTH, is nothing but the real existence of things conformable to the ideas which we have annexed to their names.

TRUTINATION, the act of weighing or ballancing a thing. See BALLANCE.

TRY, in the sea-language. A ship is said to try, or lie a-try, when no sails are abroad but the main-sail, or mizzen-sail.

TSIN, in natural history, the name given by the Chinese to a stone which they make great use of in their manufacture of porcelain ware. It is of a deep blue colour, much resembling Roman vitriol in appearance, and is found in lead mines, and supposed to contain some particles of lead; its effects being the same in the porcelain manufacture as those of cerufs or white lead, in making the other colours penetrate into the substance of the vessels. The deep violet colour that we see so beautiful on the China ware, is usually made with this stone. They find it about Canton and Peking; but the latter place affords the best, and it sells at greatly the best price. The painters in enamel melt this stone in their way, and use it very much; they form many beautiful works by laying it upon silver; but it is too apt to come off in time.

When the tsin is used in the porcelain manufacture, it is only used to the vases that pass a second baking, and are intended as the best kinds.

The tsin is prepared by only beating it to powder, not roasting it in the common way. They mix the powder with large quantities of water; and, stirring it together, they let it subside a little to separate any earthy or extraneous matter that might be among it. They then let the powder subside. The water which is thrown away has no colour from this matter; and the powder itself is not of that fine blue it was in the lump, but of a pale ash-colour; but this recovers all its beauty, when it is laid on the china and baked.

The settlement taken from the water is dried and preserved in powder, and, when it is to be used, they only mix it up with gum-water, or a solution of glue, and lay it on with a pencil.

TUB, in commerce, denotes an indeterminate quantity or measure: thus, a tub of tea contains about sixty pounds; and a tub of camphor from fifty-six to eighty pounds.

TUBBER, or TUBBLE, in mining, a name given in Cornwall to that mining instrument, which is in other parts of England called a beele.

It is an iron instrument, pointed at each end, and having a hole in the middle for the handle.

TUBE, *Tubus*, in general, a pipe, conduit, or canal; a cylinder hollow within side, either of lead, iron, wood, glass, or other matter, for the air or some other fluid to have a free passage or conveyance through.

Small silver or leaden tubes are frequently used by surgeons to draw off blood, matter, or water, from the different parts of the body. They are made of various sizes and shapes, as represented in plate CXXXIV. *fig.* 1. at the letters P, Q, R, S, T, V, X; the uses of which will be shewn at large under the articles WOUND, PARACENTESIS, &c.

TUBE, in astronomy, is sometimes used for a telescope, or, more properly, for that part thereof into which the lenses are fitted, and by which they are directed and used. The goodness of the tube being of great importance to that of the telescope, we shall here add its structure.

The Construction of a Draw-Tube for a Telescope. The chief points to be regarded here are, that the tube be not troublesome by its weight, nor liable to warp and disturb the position of the glasses; so that every kind of tube will not serve in every case.

1. If the tube be small, it is best made of thin brass-plates covered with tin, and formed into pipes or draws, to slide within one another. 2. For long tubes, iron would be too heavy, for which reason some choose to make them of paper, thus: a wooden cylinder is turned, of the length of the paper to be used, and of a diameter equal to that of the smallest draw: about this cylinder is rolled paper till it be of a sufficient thickness; when one pipe is dry provide others, after the same manner, still making the last serve for a mould to the next, till you have enough for the length of the tube desired. Lastly, to the extremes of the draws are to be glewed wooden ferrils, that they may be drawn forth the better.

3. Since paper draws are apt to swell with moist weather, so as to spoil their sliding; and in dry weather to shrink, which renders them loose and tottering; in both which cases the situation of the lens is easily disturbed; the best method of making of tubes is as follows: Glue

parchment round a wooden cylinder, and let the parchment be coloured black, to prevent the reflecting rays making any confusion: provide very thin slits of beech, and bending them into a cylinder glue them carefully to the parchment; cover this wooden case with white parchment, and, about its outer extreme, make a little ring or ferril: after the same manner, make another draw over the former, and then another, till you have enough for the length of the tube.

To the inner extremes of each draw fit a wooden ferril, that the spurious rays, striking against the sides, may be intercepted and lost. In these places where the lenses are to be put, it will be proper to furnish the ferrils with female screws. Provide a wooden cover to defend the object-glass from the dust; and, putting the eye-glass in its wooden ferril, fasten it by the screw to the tube. Lastly, provide a little wooden tube of a length equal to the distance the eye-glass is to be from the eye, and fit it to the other extreme of the tube.

TUBER, or **TUBERCLE**, in botany, a kind of round turgid root, in form of a knob or turnip.

The plants which produce such roots are hence denominated tuberose, or tuberous, plants.

TUBER, or **TUBEROSITY**, in medicine, is used for a knob, or tumour, growing naturally in any part; in opposition to tumours, which arise accidentally, or from disease.

TUBERCLES, among physicians, denote little tumours which suppurate and discharge pus, and are often found in the lungs, especially of consumptive persons.

TUBEROSE, *Polianthes*, in botany. See **POLIANTHES**.

The varieties of this plant are the tuberose with a double flower, the striped-leaved tuberose, and the tuberose with a smaller flower; the last is mentioned by several authors as a distinct species, but is certainly a variety.

This sort is frequent in the south of France, from whence the roots have been often brought to England early in the spring, before those roots have arrived from Italy, which are annually imported; the stalks of this are weaker, and do not rise so high, and the flowers are smaller than those of the common tuberose, but in other respects is the same.

The tuberose grows naturally in India, from whence it was first brought to Europe, where it now thrives in the warmer parts, as well as in its native soil. The Genoese are the people who cultivate this plant, to furnish all the other countries where the roots cannot be propagated without great trouble and care, and from thence the roots are annually sent to England, Holland, and Germany. In most parts of Italy, Sicily, and Spain, the roots thrive and propagate without care, where they are once planted.

This plant has been long cultivated in the English gardens, for the exceeding beauty and fragrancy of its flowers; the roots of this are annually brought from Genoa, by the persons who import orange trees; for as these roots are too tender to thrive in the full ground in England, so there are few persons who care to take the trouble of nursing up their off-sets, till they become blowing roots, because it will be two or three years before they arrive to a proper size for producing flowers; and as they must be protected from the frost in winter, the trouble and expence of covers is greater than the roots are worth; for they are generally sold pretty reasonable, by those who import them from Italy.

The double flowering is a variety of the first, which was obtained from seed by Mons. Le Cour, of Leyden in Holland, who for many years was so tenacious of parting with any of the roots, even after he had propagated them in such plenty, as to have more than he could plant, that he caused them to be cut in pieces, that he might have the vanity to boast of being the only person in Europe who was possessed of this flower; but of late years the roots have been spread into many parts; and as there is no method to propagate this but by the off-sets, most people who have had of this sort, are careful to multiply and increase it, which is done by planting the off-sets upon a moderate hot-bed early in March, and covering the bed in cold weather with mats or straw; in

summer they must have plenty of water in dry weather. In this bed the roots may remain till the leaves decay in autumn; but if there should happen any frost before that time, the bed should be covered to guard the roots from the frost, because if the frost enters so low as to reach the roots, it will kill them; and if the leaves are injured by the frost, it will weaken the roots. Where there is a due care taken to screen them from frost, and too much wet, it will be the best way to let the roots remain in the bed till the end of November, or the beginning of December, provided hard frosts do not set in sooner; for the less time the roots are out of the ground, the stronger they will be, and the sooner they will flower. When the roots are taken up, they should be cleaned from the earth, and laid up in dry sand, where they may be secure from frost and wet; here they should remain until the season for planting them again: this same method should be practised by those who are desirous to cultivate the single sort in England, and also that with striped leaves must be propagated the same way.

We shall next give directions for the management of those roots which are annually brought from Italy. And first, in the choice of the roots, those which are the largest and plumpest, if they are perfectly firm and sound, are the best, and the fewer off-sets they have, the stronger they will flower; but the under part of the roots should be particularly examined, because it is there that they first decay. After the roots are chosen, before they are planted, the off-sets should be taken off; for if these are left upon the roots, they will draw away part of the nourishment from the old root, whereby the flower-stems will be greatly weakened.

As the roots commonly arrive in England in the month of February or March, those who are desirous to have these early in flower, should make a moderate hot-bed soon after the roots arrive, which should have good rich earth laid upon the dung, about seven or eight inches deep; this bed should be covered with a frame, and when the bed is in a proper temperature for warmth, the roots should be planted at about six inches distance from each other every way. The upper part of the root should not be buried more than one inch in the ground; when the roots are planted, there should be but little water given them, until they shoot above ground, for too much wet will rot them, when they are in an inactive state, but afterward they will require plenty of water, especially when the season is warm. When the flower stems begin to appear, the bed should have a large share of air given to it; otherwise the stalks will draw up weak, and produce but few flowers; for the more air these plants enjoy in good weather, the stronger they will grow, and produce a great number of flowers; therefore, towards the beginning of May, the frame may be quite taken off the bed, and hoops fastened over it, to support a covering of mats, which need not be laid over but in the night, or in very cold weather, so that by enjoying the free open air, their stems will be large; and if they are well watered in dry weather, their flowers will be large, and a great number on each stem.

The first planting will require more care than those which are designed to come after them; for in order to have a succession of these flowers, the roots should be planted at three different times, viz. the first the beginning of March, the second the beginning of April, and the third at the end of that month, or the beginning of May; but the latter beds will require a much less quantity of dung than the first, especially that bed which is the last made; for if there is but warmth enough to put the roots in motion, it is as much as will be required; and this last bed will need no covering, for many times those roots which are planted in the full ground at this season, will produce strong flowers in autumn; but in order to secure their flowering, it is always the best way to plant them on a gentle hot-bed. As to the second bed, that should be arched over with hoops, and covered with mats every night, and in bad weather, otherwise the late frosts which frequently happen in May, will pinch them.

These plants may remain in the beds until the flowers are near expanding, at which time they may be carefully

T U B

fully taken up, preserving the earth to their roots, and planted in pots, and then placed in the shade for about a week to recover their removal; after which time the pots may be removed into halls, or other apartments, where they will continue in beauty a long time, and their fragrant odour will perfume the air of the rooms where they are placed, and by having a succession of them, they may be continued from Midsummer to the end of October, or middle of November; but as the stems of these plants advance, there should be some sticks put down by each root, to which the stem should be fastened, to prevent their being broken by the wind.

It is a common practice with many people, to plant these roots in pots, and plunge the pots into a hot-bed; but there is much more trouble in raising them in this method than in that before directed; for if the roots are not planted in very small pots, there will be a necessity of making the beds much larger, in order to contain a quantity of the roots; and if they are first planted in small pots, they should be shaken out of these into pots of a larger size, when they begin to shoot out their flower stems, otherwise the stalks will be weak, and produce but few flowers; therefore the other method is to be preferred, as there is no danger in removing the roots, if it is done with care.

When the roots are strong, and properly managed, the stems will rise three or four feet high, and each stem will produce twenty flowers or more; and in this the great beauty of these flowers consists, for when there are but a few flowers upon the stalks, they will soon fade away, and must be frequently renewed; for the flowers are produced in spikes coming out alternately upon the stalk, the lower flowers opening first; and as these decay, those above them open; so that in proportion to the number of flowers upon each stalk, they continue in beauty a longer or shorter time.

The sort with double flowers will require a little more care, in order to have the flowers fair; but this care is chiefly at the time of blowing, for the flowers of this sort will not open, if they are exposed to the open air; therefore when the flowers are fully formed and near opening, the pots should be placed in an airy glass-case, or a shelter of glasses should be prepared for them, that the dews and rains may not fall upon them, for that will cause the flowers to rot away before they open, and the heat of the sun drawn through the glasses, will cause their flowers to expand very fair. With this management, Mr. Miller says he has had this sort with very double flowers extremely fair, and upwards of twenty upon one stem, so that they have made a beautiful appearance; but where this has not been practised, it is very rare to see one of them in any degree of beauty.

TUBEROUS, or TUBEROSE-ROOTS, in botany. See **TUBER**.

TUBIPORA, or TUBULARIA, a genus of submarine plants, belonging to the cryptogamia class, of the hardness of coral, and consisting of cylindric tubes rising from a thin crust of the same sort of matter with themselves.

TUBULARIA FOSSILIS, in natural history, the name of a species of coral found very often fossil in Germany and Italy, and composed of a great number of tubes, or longitudinal pipes, often resembling so many worms ranged perpendicularly in the mass. They are usually found either in masses of a lax stone, or in single tubules in those of the harder and firmer texture. In these two states, this fossil makes two very different appearances; and, according to the different directions in the mass, or the different views of them that the sections of it place them in, they make a number of very elegant figures.

TUBULATED FLOWER, *Tubulatus Flosculus*, in botany, a term used by authors to express those smaller flowers, a great number of which go to compose one large compound flower. These are called tubulated in distinction from another kind of them, which are from their shape called ligulated. The tubulated floscules generally compose the disk, and the ligulated ones the radius of the compound flowers. The tubulated ones are formed into a hollow cylinder, which expands into a mouth at

T U L

the top, and is divided into five equal segments, which stand expanded, and in some measure bent backwards.

TUBULI FOSSILIS, in natural history, the tubules, or cases of sea-worms, found buried in the earth. They are met with of various sizes, sometimes complete, and buried in the strata of earth or stone; sometimes they are more or less perfect, and are immersed in masses of the ludus helmontii or septariae, and in this state they make one kind of lapis syringoides, or pipe-stone; but the most beautiful syringoides, or pipe-stones, are the parts of the bottoms of ships, or posts fixed in the sea, which have been pierced in their original state of wood, by these sea-worms, and afterwards petrified with the cases or tubuli of the worms remaining in them; these are usually of a pale-yellow or whitish wax colour, and the body of the mass of a brownish or blackish hue, but retaining the structure of the wood: of these there are beautiful specimens in great abundance on the shore of the island Sheppy. We have the very same substances also buried in our clay-pits, about London and at Richmond; but in these the wood is highly saturated with the matter of the common vitriolic pyrites, and the pipes often filled with the same substance.

TUBULI LACTIFERI, in anatomy, the small tubes or vessels, through which the milk flows to the nipples of women's breasts.

TUBULUS MARINUS, or CANALIS, in natural history, a genus of univalve shells, of an oblong figure, terminating in a point, and hollow within, so as to resemble a tube or horn; and hence have, by some old writers, been called dentalia.

Of these shells some are striated, some straight, some bent like a horn, and some in form of a crescent.

TUCK of a Ship, the trussing or gathering up the quarter under water; which if she lie deep, makes her have a broad, or, as they call it, fat quarter, and hinders her steering, by keeping the water from passing swiftly to her rudder; and if this trussing lie too high above the water, she will want bearing for her works behind, unless her quarter be very well laid out.

TULIP, *Tulipa*, in botany, a genus of plants, the flower of which has no empalement; it is of the bell-shape, composed of six oblong, oval, concave, erect petals; it has six awl-shaped stamina, which are shorter than the petals, terminated by oblong four-cornered summits, and a large oblong, taper, three cornered germen, having no style, crowned by a triangular, three-lobed, permanent stigma. The germen afterwards turns to a three-cornered capsule, having three cells, which are filled with compressed seeds, lying over each other in a double order.

There are two species of tulips: the first sort was formerly preserved in the English gardens; but since there has been so many varieties of the second sort propagated in England, the first has been rejected, and is now only to be found in old neglected gardens. The petals of this flower end in acute points; the flower is yellow, and nods on one side, and the leaves are narrower than those of the common sort.

The common tulip is so well known as to need no description; and it would be to little purpose to enumerate the several varieties of these flowers, which may be seen in one good garden, since there is no end of their numbers; and what some people may value at a considerable rate, others reject: besides, there are annually a great variety of new flowers obtained from breeders, so those which are old, if they have not very good properties to recommend them, are thrown out and despised. I shall therefore point out the properties of a good tulip, according to the characteristics of the best florists of the present age. 1. It should have a tall strong stem. 2. The flower should consist of six leaves, three within, and three without; the former ought to be larger than the latter. 3. Their bottom should be proportioned to their top, and their upper part should be rounded off, and not terminate in a point. 4. These leaves, when opened, should neither turn inward, nor bend outward, but rather stand erect, and the flower should be of a middling size, neither over large, nor too small. 5. The stripes should be small and regular, arising from the bottom of the flower; for if there are any remains of the former

former self-coloured bottom, the flower is in danger of losing its stripes again. The chives should not be yellow, but of a brown colour. When a flower has all these properties, it is esteemed a good one.

Tulips are generally divided into three classes, according to their seasons of flowering; as *Præcoces*, or early blowers, *Medias*, or middling blowers, and *Serotines*, or late blowers; but there is no occasion for making any more distinctions than two, viz. early and late blowers.

The early blowing tulips are not near so fair, nor rise half so high, as the late ones, but are chiefly valued for appearing so early in the spring; some of which will flower the end of February in mild seasons, if planted in a warm border near a wall, pale, hedge, or other shelter, and a month after the others will succeed them; so that they keep flowering until the general season for the late flowers to blow, which is towards the end of April.

The roots of the early-blowing tulips should be planted the beginning of September in a warm border, near a wall, pale, or hedge, because if they are put into an open spot of ground, their buds are in danger of suffering by morning frosts in the spring. The soil for these should be renewed every year, where people intend to have them fair. The best soil for this purpose is that which is taken from a light loamy pasture, with the turf rotted amongst it; and to this should be added a fourth part of sea-sand. This mixture may be laid about eighteen inches deep, which will be sufficient; for these need not be planted more than four or five inches deep at most. The off-sets should not be planted amongst the blowing roots, but in a border by themselves, where they may be planted pretty closely together, especially if they are small; but these should be taken up when their leaves decay, in the same manner as the blowing roots, otherwise they would rot; for these are not so hardy as the late blowers, nor do they increase half so fast as those, so that a greater care is required to preserve the off-sets of them.

When these tulips come up in the spring, the earth upon the surface of the borders should be gently stirred and cleared from weeds; and as the buds appear, if the season should prove severe, it will be of great service to cover them with mats, for want of which many times they are blighted, and their flower-buds decay before they blow, which is often injurious to the roots, as also the cropping of the flowers so soon as they are blown, because their roots, which are formed new every year, are not at that time arrived to their full magnitude, and are hereby deprived of proper nourishment.

If, when these flowers are blown, the season should prove very warm, it will be proper to shade them with mats, &c. in the heat of the day; as also if the nights are frosty, they should be in like manner covered, whereby they may be preserved a long time in beauty; but, when their flowers are decayed, and their seed vessels begin to swell, they should be broken off just at the top of the stalks, because if they are permitted to seed, it will injure the roots.

When the leaves of these flowers are decayed, which will be before the late blowers are out of flower, their roots should be taken up, and spread upon mats in a shady place to dry; after which they should be cleared from their filth, and put up in a dry place, where vermin cannot come to them, until the season for planting them again, being very careful to preserve every sort separate, that you may know how to dispose of them at the time for planting them again, because it is the better way to plant all the roots of each sort together, and not to intermix them, as is commonly practised in most other kinds of flowers; for as there are few of them which blow at the same time, so, when the several roots of one sort are scattered through a whole border, they make but an indifferent appearance; whereas, when twenty or thirty roots of the same sort are placed together, they will all flower at the same time, and have a better effect.

There are many curious persons, who, in order to preserve their several kinds of tulips, and other bulbous-rooted flowers separate, have large flat boxes made, which are divided into several small partitions, each of

which is numbered in the same manner as the divisions of their beds; so that when a catalogue of their roots is made, and the numbers fixed to each sort in the beds, there is nothing more to do when the roots are taken up, but to put every kind into the division marked with the same number which was placed to each sort in the bed, which saves a great deal of trouble, and effectually answers the purpose of preserving the kinds separate.

The late-blowing tulips are so numerous, that, as I before observed, it would be to no purpose to attempt to give a catalogue of them. These are generally obtained from breeders, which is a term applied to all such flowers as are produced from seeds which are of one self-colour, and have good bottoms and chives; these in time break into various beautiful stripes, according to the ground of their former self-colour; but this must be entirely thrown off, otherwise they do not esteem a flower well broken.

Of these breeders there hath been a great variety brought into England from Flanders of late years, which is the grand nursery for most sorts of bulbous-rooted flowers; but there are some curious persons, who have lately obtained many valuable breeders from seed in England; and doubtless, were we as industrious to sow the seeds of these flowers as the people of Holland and Flanders, we might in a few years have as great variety as is to be found in any part of Europe; for, although it is six or seven years from the sowing before these flowers blow, yet, if after the first sowing there is every year a fresh parcel sown, when the seven years are expired, there will be constantly a succession of roots to flower every year, which will reward the expectation, and keep up the spirit of raising; but it is the length of time at first, which deters most people from this work.

The manner of propagating these flowers from seeds is as follows: you should be careful in the choice of the seeds, without which there can be little success expected. The best seed is that which is saved from breeders which have all the good properties before related, for the seeds of striped flowers seldom produce any thing that is valuable.

The best method to obtain good seeds is to make choice of a parcel of such breeding tulip roots as you would save seeds from, and plant them in a separate bed from the other breeders, in a part of the garden where they may be fully exposed to the sun, observing to plant them at least eight or nine inches deep; for if they are planted too shallow, their stems are apt to decay before their seed is perfected.

These flowers should always be exposed to the weather, for if they are shaded with mats, or any other covering, it will prevent their perfecting the seed. About the middle of July, a little sooner, or later, as the summer is hotter or colder, the seeds will be fit to gather, which may be known by the dryness of their stalks, and the opening of the seed vessels; at which time it may be cut off, and preserved in the pods till the season for sowing it, being careful to put it up in a dry place, otherwise it will be subject to mould, which will render it good for little.

Having saved a parcel of good seed, about the beginning of September is the best season for sowing it, when there should be provided a parcel of shallow seed pans or boxes, six or eight inches deep, which should have holes in their bottoms to let the moisture pass off; these must be filled with fresh light earth, laying the surface very even, upon which the seeds should be sown as regularly as possible, that they may not lie upon each other; then there should be some of the same light earth sifted over them; about half an inch thick. These boxes or pans should be placed where they may have the morning sun till eleven of the clock, in which situation they may remain until the middle of October, at which time they should be removed into a more open situation, where they may enjoy the benefit of the sun all the day, and be sheltered from the north winds, where they should remain until winter, when they must be placed on a south border, to screen them from frost; but in the spring, when the plants are up, they should be again removed to their first situation; and if the season should be dry, they must be refreshed with water, while the plants

plants remain green, but as soon as their tops begin to decay, there must be no more given them, lest it rot their tender bulbs; therefore the boxes should be placed in a shady situation during the summer season, but not under the drip of trees.

These plants, at their first appearance, have very narrow grassy leaves, very like those of onions, and come up with bending heads, in the same manner as they do; so that persons who are unacquainted with them, may pull them up instead of grass, whilst they are very young, before their leaves are a little more expanded; which is not performed the first year, for they seldom appear before the middle of March; and they commonly decay about the latter end of May, or the beginning of June, according as the season is hotter or colder.

The weeds and moss should also be cleared off from the surface of the earth in the boxes, and a little fresh earth sifted over them soon after their leaves decay, which will be of great service to the roots. These boxes should be constantly kept clear from weeds, which, if permitted to grow therein, when they are pulled up, their roots will be apt to draw the bulbs out of the ground. At Michaelmas they should be fresh earthed again, and as the winter comes on, they must be again removed into the sun as before, and treated in the same manner, until the leaves decay, when the bulbs should be carefully taken up, and put in a cool shady room till the end of August, when they should be planted in beds of fresh sandy earth, which should have tiles laid under them, to prevent the roots from shooting downward, which they often do when there is nothing to stop them, and thereby they are destroyed. The earth of these beds should be about five inches thick upon the tiles, which will be sufficient for nourishing these roots while they are young.

The distance which these young bulbs should be allowed, need not be more than two inches, nor should they be planted above two inches deep; but towards the end of October it will be proper to cover the bed over with a little tanner's bark, about two inches deep, which will preserve the roots from the frost, and prevent moss or weeds from growing over them; but, if the winter should be very severe, it will be proper to cover the bed either with mats or pease-haulm, to prevent the frost from entering the ground, because these roots are much tenderer while young, than they are after they have acquired strength.

In the spring the surface of the ground should be gently stoned to make it clean, before the plants come up; and if the spring should prove dry, they must be frequently refreshed with water, during the time of their growth; but this must not be given to them in great quantities, lest it rot their tender bulbs; and when the leaves are decayed, the roots should be taken up and treated in the same way as before.

When the bulbs are large enough to blow, they should be planted in fresh beds at the distance, and in the same manner as old roots, where, when they flower, such of them as are worthy to be preserved should be marked with sticks; and at the season for taking up the bulbs, they must be separated from the others, in order to be planted as breeders in different beds; but you should by no means throw out the rest until they have flowered two or three years, because it is impossible to judge exactly of their value in less time; for many, which at first flowering appear beautiful, will afterwards degenerate so as to be of little value; and others, which did not please at first, will many times improve, so that they should be preserved until their worth can be well judged of.

Having thus given an account of the method of raising these flowers from seeds, I shall now proceed to the management of the roots which are termed breeders, so as to have some of them every year break out into fine stripes.

There are some who pretend to have a secret how to make any sort of breeders break into stripes whenever they please; but this, I dare say, is without foundation; for from many experiments which I and others have made of this kind, I could never find any certainty in this. All that can be done by art is, to shift the roots

every year into fresh earth of different mixtures and to different situations, by which method I have had very good success.

The earth of these beds should be every year different; for although it is generally agreed that lean, hungry, fresh earth doth hasten their breaking, and cause their stripes to be the finer and more beautiful, yet, if they are every year planted in the like soil, it will not have so much effect upon them, as if they were one year planted in one sort of earth, and the next year in a very different one; as I have several times experienced; and if some fine striped tulips are planted in the same beds with the breeders, intermixing them together, it will also cause the breeders to break the sooner.

The best compost for these roots is a third part of fresh earth from a good pasture, which should have the sward rotted with it, a third part of sea-sand, and the other part sifted lime rubbish; these should be all mixed together six or eight months at least before it is used, and should be frequently turned to mix the parts well together. With this mixture the beds should be made about two feet deep, after the following manner: After the old earth is taken from out of the bed to the depth intended, then some of the fresh earth should be put in about eighteen inches thick; this should be levelled exactly, and then lines drawn each way of the bed chequerwise, at six inches distance; upon the center of each cross, should be placed the tulip roots, in an upright position; and after having finished the bed in this manner, the earth must be filled in, so as to raise the bed six or eight inches higher, observing, in doing this, not to displace any of the roots, and also to lay the top of the beds a little rounding, to throw off the wet.

There are many persons who are so careless in planting their tulip roots, as only to dig and level the beds well, and then with a blunt dibble to make holes, into which they put the roots, and then fill up the holes with a rake; but this is by no means a good method; for the dibble, in making the holes, presses the earth closely on each side, and at the bottom, whereby the moisture is often detained so long about the roots as to rot them, especially if the soil is inclinable to bind; besides, the earth being hard at the bottom of the bulbs, they cannot so easily emit their fibres, which must certainly prejudice the roots.

These beds should be sunk, more or less, below the surface, according to the moisture or dryness of the ground; for the roots should be so elevated as never to have the water stand near the reach of their fibres in winter, for moisture is very apt to rot them; so that where the soil is very wet, it will be proper to lay some lime rubbish under the earth, in order to drain off the wet, and the beds should be entirely raised above the level of the ground; but to prevent their falling down into the walks, after frost, or hard rains, it will be proper to raise the paths between them, either with sea-coal ashes or rubbish, eight or ten inches, which will support the earth of the beds; and these paths may slope at each end from the middle, which will make passage for the water to run off as it falls. But where the soil is dry, the beds may be sunk eighteen or twenty inches below the surface, for in such places the beds need not be more than four or six inches above the surface, which will be allowance enough for their settling.

During the winter season there will be no farther care required. The roots being planted thus deep, will be in no danger of suffering by ordinary frosts; but if the winter should prove very severe, some rotten tan or pease-haulm may be laid over the beds to keep out the frost during its continuance, but this must be removed when the frost is over; and in the spring, when their leaves begin to appear above ground, the earth upon the surface of the beds should be stirred to clear it from weeds, moss, &c. and when the flower-buds begin to come up, they should be guarded from frost, otherwise they are very subject to blight and decay soon after they appear, if the frost pinches their tops; but they need only be covered in such nights when there is a prospect of frost, for at all other times they should have as much open air as possible, without which they will draw up weak, and produce very small flowers.

When these breeders are in flower, you should carefully examine them to see if any of them have broken into beautiful stripes, which, if you observe, there should be a stick put into the ground by every such root to mark them, that they may be separated from the breeders, to plant amongst the striped flowers the following year; but you should carefully observe, whether they have thrown off their former colour entirely, as also when they decay, to see if they continue beautiful to the last, and not appear smeared over with the original colour; in both which cases they are very subject to go back to their old colour the next year: but if their stripes are distinct and clear to the bottom, and continue so to the last, which is what the florists call dyeing well, there is no great danger of their returning back again, as hath been by some confidently reported; for if one of these flowers is quite broken, as it is termed, it will never lose its stripes, though sometimes they will blow much fairer than at others, and the flowers of the off-sets will be often more beautiful than those of the old roots.

This alteration in the colour of these flowers may be seen long before they are blown, for the green leaves will appear of a fainter colour, and seem to be striped with white, or of a brownish colour, which is a plain proof, that the juices of the whole plant are altered, or, at least, the vessels through which the juice is strained; so that hereby particles of a different figure are capable of passing through them, which, when entered into the petals of the flower, reflect the rays of light in a different manner, which occasions the variety we see in the colours of flowers. This breaking of the colours in flowers proceeds from weakness, or at least is the cause of weakness in plants; for it is observable, that after tulips are broken into fine stripes, they never grow so tall as before, nor are the stems, leaves, or flowers so large; and it is the same in all variegated plants and flowers whatever, which are also much tenderer than they were before they were striped; so that many sorts of exotic plants, which by accident have become variegated in their leaves, are often rendered so tender, as not to be preserved without much more care, though indeed the striping of tulips doth never occasion so great weakness in them as to render them very tender. The greatest effect it hath on them, is in lessening their growth; the more beautifully their stripes appear, the shorter will be their stems, and the weaker their flowers.

There is nothing more to be observed in the culture of striped flowers than what has been directed for breeders, excepting that these should be arched over with tall hoops and rails, that they may be shaded from the sun in the day-time, and protected from strong winds, hard rains, and frosty mornings, otherwise the flowers will continue but a short time in beauty; but where these instructions are duly followed, they may be preserved in flower a full month, which is as long as most flowers continue.

There are some persons who are so extremely fond of these flowers, as to be at a great expence in erecting large frames of iron work to cover their beds of tulips, in such a manner, that they may walk between two beds under the frames, over which are spread tarpawlings, so as to keep off sun, rain, and frost, whereby they can view the flowers without being at the trouble of taking off or turning up the tarpawlings, or being incommoded by the sun or rain, which cannot be avoided where the covering is low; besides, by thus raising the covers, the flowers have a greater share of air, so that they are not drawn so weak as they are when the covering is low and close to them; but these frames being expensive, can only be made by persons of fortune; however, there may be some of wood contrived at a smaller expence, which, being arched over with hoops, may answer the purpose as well as the iron frames, though they are not so lightly or lasting.

When the flowers are faded, the heads of all the fine sorts should be broken off, to prevent their seeding; for if this is not observed, they will not flower near so well the following year, nor will their stripes continue so perfect: this will also cause their stems to decay sooner

than otherwise they would do, so that their roots may be taken up in June; for they should not remain in the ground after their leaves are decayed. In taking the roots out of the ground, you must be very careful not to bruise or cut them, which will endanger their rotting, and, if possible, it should be done a day or two after rain. When these roots are taken out of the ground, they must be cleared from their old covers, and all sorts of filth, and spread upon mats in a shady place to dry; after which they should be put up in a dry place, where vermin cannot get to them, observing to keep every sort separated; but they should not be kept too close from the air, nor suffered to lie in heaps together, lest they should grow mouldy; for if any of the roots once take the mould, they commonly rot when they are planted again.

The offsets of these roots, which are not large enough to produce flowers the succeeding year, should be also put by themselves, keeping each sort distinct: these should be planted about a month earlier in autumn than the blowing roots, in particular beds by themselves, in the flower-nursery, where they may not be exposed to public view; but the earth of the beds should be prepared for them in the same manner as for larger roots; these should not be planted above five inches deep, because they are not strong enough to push through so great covering of the earth as the old roots; they may also be placed much nearer together than those which are to flower, and in one year most of them will become strong enough to flower, when they may be removed into the flower-garden, and placed in the beds amongst those of the same kinds. *Miller's Gard. Dict.*

TULIP TREE, a very beautiful American tree, which produces flowers, supposed like those of the tulip.

This tree, which is a native of North America, and where it grows to be a tree of the first magnitude, is generally known through all the English settlements by the title of poplar. Of late years there has been great numbers of these trees raised from seeds in the English gardens, so that now they are become common in the nurseries about London, and there are many of the trees in several parts of England which do annually produce flowers. The first tree of this kind which flowered here, was in the gardens of the late earl of Peterborough at Parsons-Green near Fulham, which was planted in a wilderness among other trees. Before this was planted in the open air, the few plants which were then in the English gardens, were kept in pots or tubs, and housed in winter, supposing they were too tender to live in the open air; but this tree, soon after it was planted in the full ground, convinced the gardeners of their mistake, by the great progress it made, while those which were kept in pots and tubs, increased slowly in their growth; so that afterwards there were many others planted in the full ground, which are now arrived to a large size, especially those which were planted in a moist soil. One of the handsomest trees of this kind near London, is in the garden of Waltham-Abbey; and at Wilton, the seat of the earl of Pembroke, there are some trees of great bulk; but the old tree at Parsons-Green is quite destroyed by the other trees which were suffered to overhang it, and rob it of its nourishment, from a fear of taking down the neighbouring trees, and admitting the cold air to the tulip-tree, it should injure it.

The young shoots of this tree are covered with a smooth purplish bark, garnished with large leaves, whose foot-stalks are long; they are ranged alternate; the leaves are of a singular form, being divided into three lobes; the middle lobe is blunt and hollowed at the point, appearing as if it had been cut with scissars. The two side lobes are rounded, and end in blunt points. The upper surface is smooth, and of a lucid green; the under is of a pale green. The flowers are produced at the end of the branches; they are composed of six petals, three without and three within, which form a sort of bell-shaped flower, from whence the inhabitants of North America gave it the name of Tulip. These petals are marked with green, yellow and red spots, so make a fine appearance when the trees are well charged with flowers. The time of this tree's flowering is in July, and when the flowers drop, the germen swells

and forms a kind of cone; but these do not ripen in England.

This tree is propagated by seeds, which are now annually imported in great plenty from America. These should be sown as soon as they arrive, in pots or tubs, filled with light earth, from the kitchen garden, or in a bed in the full ground. Those which are sown in the first way, may be placed on a very gentle hot bed, which will forward their growth; so that if they come up the same season, the plants will acquire more strength before winter. When the plants appear, they must be shaded in the heat of the day from the sun, but fresh air must be admitted daily to prevent their drawing up weak; and as the season advances, they must be gradually hardened to bear the open air. While the plants are young they do not care for much sun, so they should be either shaded, or placed where the morning sun only shines upon them; they must also be constantly supplied with water, but not have it in too great plenty. As the young plants commonly continue growing late in the summer, so when there happens early frosts in autumn, it often kills their tender tops, which occasions their dying down a considerable length in winter; therefore they should be carefully guarded against these first frosts, which are always more hurtful to them than harder frosts afterwards, when their roots are better hardened; however, the first winter after the plants come up, it will be the better way to shelter them in a common hot-bed frame, or to arch them over with hoops, and cover them with mats, exposing them always to the open air in mild weather.

The following spring, just before the plants begin to shoot, they should be transplanted into nursery beds, in a sheltered situation, where they are not too much exposed to the sun. The soil of these beds should be a soft gentle loam, not too stiff, nor over light; this should be well wrought, and the clods well broken and made fine. There must be great care taken not to break the roots of the plants in taking them up, for they are very tender; then they should be planted again as soon as possible, for if their roots are long out of the ground, they will be much injured thereby. These may be planted in rows at about a foot distance, and at six inches distance in the rows; for as they should not remain long in these nursery-beds, so this will be room enough for them to grow; and by having them so close, they may be shaded in the summer, or sheltered in the winter, with more ease than when they are farther apart.

When the plants are thus planted, if the surface of the beds is covered with rotten tanners bark, or with moss, it will prevent the earth from drying too fast; so that the plants will not require to be so often watered, as they must be where they are exposed to the sun and air; after this, the farther care will be to keep them clean from weeds, and if the latter part of summer should prove moist, it will occasion the plants growing late in autumn, so their tops will be tender and liable to be killed by the first frosts. In this case they should be covered with mats to protect them.

If the plants make great progress the first summer, they may be transplanted again the following spring; part of them may be planted in the places where they are to remain, and the other should be planted in a nursery where they may grow two years, to acquire strength before they are planted out for good; though the younger they are planted in the places where they are to stand, the larger they will grow, for the roots run out into length; and when they are cut, it greatly retards their growth, so that these trees should never be removed large; for they rarely succeed, if transplanted, when they are grown to a large size. Some indeed that have been removed pretty large, have survived their removal; but young plants of two years old, which were planted near them, were much larger in fifteen years than the old ones.

When the seeds are sown upon a bed in the full ground, the bed should be arched over with hoops, and shaded in the heat of the day from the sun, and frequently refreshed with water; as should also the plants when they appear, for when they are exposed much to the sun while young, they make but small progress.

The care of these in summer must be to keep them clean from weeds, supplying them duly with water, and shading them from the sun in hot weather; but as these seeds will not come up so soon as those which were placed on a hot-bed, they generally continue growing later in autumn, therefore will require shelter from the early frosts in autumn; for as the shoots of these will be much softer than those of the plants which had longer time to grow, so if the autumnal frosts should prove severe, they will be in danger of being killed down to the surface of the ground, by which the whole summer's growth will be lost; and sometimes the plants are entirely killed the first winter, if they are not protected.

As these plants will not have advanced so much in their growth as the other, they should remain in the seed-bed to have another year's growth before they are removed; therefore all that will be necessary to observe the second year, is to keep them clean from weeds; and now they will not be in so much danger of suffering from the warmth of the sun as before, therefore will not require such constant care to shade them, nor should the watering of them be continued longer than the spring; for if the autumn should prove dry, it will prevent the plants from shooting late, and harden those shoots which were made early in the year, whereby the plants will be in less danger from the early frosts.

After the plants have grown two years in the seed-bed, they will be strong enough to remove; therefore, in the spring, just at the time when their buds begin to swell, they should be carefully taken up, and transplanted into nursery-beds, and treated in the same way as has been before directed for the plants which were raised in pots.

There are some people who propagate this tree by layers, but the layers are commonly two or three years before they take root; and the plants so raised, seldom make such straight trees as those raised from seeds, tho' indeed they will produce flowers sooner, as is always the case with stunted plants.

This tree should be planted on a light loamy soil, not too dry, on which it will thrive much better than upon a strong clay, or a dry gravelly ground; for in America they are chiefly found upon a moist light soil, where they will grow to a prodigious size, though it will not be proper to plant these trees in a soil which is too moist, in England, because it might endanger the rotting of the fibres of the roots, by the moisture continuing too long about them, especially if the bottom be a clay, or a strong loam, which will detain the wet. *Miller's Gar. Dict.*

TUMBLER, a name given to a particular species of pigeon, called by Moore the columba revolvens.

It has its name from its peculiar property of tumbling, when it is in the air, which they are very fond of doing; and effect exactly in the same manner as our posture-masters do it, by throwing themselves over backwards. It is a very small pigeon, and is always short-bodied, full-breasted, thin-necked, narrow-beaked, and has a small short head; the iris of the eye, in this species, is usually of a bright pearl-colour.

The English tumbler is usually of one plain colour; black, blue, or white: the Dutch is much of the same make, but has different colours, and is feathered on the legs sometimes; it has also a larger head, and thin skin round the eye. Some of the finest pigeons of this sort are bred from a mixture of the Dutch and English kinds.

These pigeons are remarkable for the height they fly to; they never ramble far from home, but will rise almost perpendicularly, till they appear no larger than a sparrow, or become quite out of sight: they will often keep at this height five or six hours, and then come gradually down again: they will never tumble when they are at any great height, but only as they ascend or come down again. There are particular times also, at which those birds will take much higher flights than at others; but they ought to be kept by themselves, and practised to it by the company of one of their own species; for if they mix, while young, with other pigeons, they will learn to fly as they do: a flight of a dozen of these birds sent out together will keep so close as to be all in a compass that might be covered with a handkerchief; but they should never be turned out in foggy weather, or in high

high winds; in the first case they lose sight of their home, and perhaps never find it again, and, in the others, they are blown away; and, if they return, it is not till another day: in the mean time, lying out, they are in danger of cats, and other accidents.

Lastly, the hen should never be turned out with egg, for she is then sick, and not fit for flying; and, besides, often drops her egg, and the breed is lost by it. *Moore's Columbarium.*

TUMBLER, is also the name of a dog, so called from his quality of tumbling and winding his body about, before he attacks and fastens on his prey.

These dogs are often less than hounds; being lanker, leaner, and some-what pricked-eared; and by the form of their bodies, they might be called mungrel greyhounds, if they were a little bigger.

TUMEFACTION, the act of swelling or rising into a tumour.

Inflammations and tumeactions of the testes frequently happen in a gonorrhœa, either from the weakness of the vessels, violent motion, unseasonable use of astringents, a neglect of purging, or the like.

TUMOR, or **TUMOUR**, in medicine and surgery, a preternatural rising or eminence on any part of the body. Tumour is also defined, by physicians, a solution of continuity arising from some humour collected in a certain part of the body, which disjoins the continuous parts, insinuates itself between them, and destroys their proper form.

Whether there be any such preternatural rising or enlargement on any part of the body, may be discovered from inspection, but more particularly by feeling. And, notwithstanding it is a general custom to refer excrescences, as warts, corns, and such as grow in the nose and pudenda, to the class of tumours; yet, because they grow not from beneath, but out of, or upon, the skin itself, it is thought proper not to comprehend them in the general division of tumours.

There are tumours of various kinds, distinguished by particular names, according to the different causes from whence they proceed, and the particular parts wherein they are seated; some are called hot, others cold and watery; some are termed windy, others schirrhous; and some are named benign, others malignant: but Heister finds fault with these distinctions. There are some tumours which being contained in a proper membrane, are therefore called cystic: and if this should be in an artery, it is usually termed aneurism; but when in a vein, a varix. When in the veins of the anus, or rectum, the disorder is termed hæmorrhoids; but if the tumour be in the scrotum, unguen, or at the umbilicus, it is generally called a hernia: if any pus, or matter, is contained in the tumour, it is called an abscess; and if the tumour is seated in a bone, it is termed exostosis.

The forementioned class of tumours are all of them subdivided into several other kinds: thus the hot and burning tumours, which are the same with inflammations, are generally termed phlegmons, when violent and seated in the common integuments; but when slighter, they are commonly called furuncles. The inflammation which is not fixed deep, but spreads only superficially upon the skin, is termed an erysipelas: the inflammatory tumour that arises at the finger-ends is termed paronychia: that which fixes in the groin or armpits is called a bubo; and that under the ears a parotis. When an inflammation seizes the hands and feet from extreme cold, chilblains arise; which tumour is called pernio.

Encysted TUMOURS, tumours arising in different parts of the body, but contained in certain membranous coats: these are sometimes harder, sometimes softer, of a palish colour, and usually attended with little pain. These tumours arise from obstructions either in the glands, or in the adipose membrane, more especially about the face and neck, where they occasion great deformity. The membranous coat with which these tumours are invested, is often of a considerable thickness, and is usually the coat of the disordered gland, or some of the adipose cells. At their beginning they are usually very small and moveable; but encreasing by slow degrees, they grow sometimes to an enormous bulk.

The consistence of some of these tumours is soft and fluctuating, and of others more hard and firm. They are of all shapes and sizes, and some of them become hard as a callus, and unmoveable, while others are, for the generality, soft and moveable.

They are distinguished according to the consistence of their contents; some are called atheromata, from their contents resembling paste; others, which have them of the consistence of honey, are called meliceræ; but if they are of a fatty substance, like suet or lard, they are called steatomata. If they happen in a gland which becomes indurated, they are called schirrhous: and lastly, when they are of a fleshy consistence, they are called sarcomata. Some of these tumours have been found also full of hair.

They are distinguished by others according to the places where they are situated.

Those seated under the scalp are called talpa, testudo, or lupia; those in the neck, strumæ or scrophulæ; and those in the hands and feet, especially if among the tendons, are called ganglions.

There is no general method for the cure of them; but the surgeon, according to their different circumstances, attempts this by discussion, suppuration, or extirpation.

But if the tumour can neither be dispersed nor suppurated, but continues to enlarge itself, it is adviseable to extirpate it in order to prevent its turning into a cancerous nature. There are several methods in practice for extirpating these tumours, according to their nature and size: those which are small and hard, or hung by a root as by a stalk, are generally best removed by ligature, in the manner of warts; by which means they wither and fall off of themselves in a few days. But the most ready and expeditious method is to cut them off with a scalpel, and then heal up the wound: but if in removing them this way you divide a considerable artery, you may stop it by some potential, or even the actual, cautery; or else, by taking it up with a needle and thread. Lastly, these tumours may be often removed by the application of caustic or corroding medicines, retained about the root by means of plasters, compresses, and a bandage; and when you find the root of the tumour almost corroded through, the rest may be divided by the scalpel.

If the root of the encysted tumour appears too large for it to be conveniently taken off by ligature, you must then remove it either by the knife or by the caustics, though the latter is usually preferred. In order to extirpate it by the knife, you must first make a longitudinal incision upon the tumour; and if that does not appear sufficient, make another incision across the former, till you think the wound large enough for taking out the tumour; in order to which you next dilate the integuments, and separate them from the cyst of the tumour, which you are to take out whole, if possible, either by means of the scalpel, a hook, or by passing a crooked needle, with a strong thread, crosswise under the tumour; but great caution is necessary in this operation, lest any important part that is contiguous to the tumour be injured.

The tumour being thus carefully extracted, if the wound and hæmorrhage be small, you may press the lips together; and by covering the same with lint and compresses, retained with a proper bandage, the patient is cured in a few days time; but in case of a profuse hæmorrhage, the blood is to be stopped either by ligature, astringents, or the actual or potential cautery.

Fungous TUMOURS. See **FUNGUS**.

Inflammatory TUMOURS. See the article **INFLAMMATION**.

Oedematous TUMOURS. See **OEDEMA**.

TUMOURS of the parotid glands. See the article **PAROTIDES**.

Pestilential TUMOURS. See the articles **BUBO** and **CARUNCLE**.

Schirrhous TUMOURS. See **SCHIRRHOUS**.

TUMOURS of the testicles. See **TESTICLES**.

TUN, or **TON**, originally signifies a large vessel or cask, of an oblong figure, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and

and used to put up several kinds of merchandize in for their better carriage, as brandy, oil, sugar, skins, hats, &c.

Some derive the word from *autumnus*, in regard it is then tuns are most needed: Du Cange derives it from *tunna* or *tonna*, words used in the base Latin for the same thing, whence also *tunnare*, to tun.

The term is also used for certain vessels of extraordinary bigness, serving to keep wine in for several years.—In Germany there are many which are scarce ever emptied: the Heidelberg tun is famous.

The tun, we frequently, though improperly, call a hoghead.

TUN, or TON, is also a certain measure for liquids; as wine, oil, &c.

The English tun contains two pipes, or four hogheads, or 252 gallons.

The tun of Amsterdam contains six aems or awms; and the aem four ankers, the anker two stekans, the stekan sixteen mingles; twelve stekans are equal to an English barrel or sixty-three gallons.

The tun of Bourdeaux and Bayonne contains four barrels, equal to three Paris muids.—At Orleans and Berry it is about two Paris muids.

The tun of Malaga, Alicant, Seville, &c. is two botta's, equal to about thirty-six or thirty-seven stekans.—The tun of Lisbon is two Portuguese botta's, equal to twenty-five stekans.

Tun is also a certain weight whereby the burthens of ships, &c. are estimated.—The sea-tun is computed to weigh forty hundred weight.

TUNE, or TONE, in music, that property of sounds whereby they come under the relation of acute and grave to one another.

Though gravity and acuteness are mere terms of relation, the tune of the sound is something absolute, every sound having its own proper tone, which must be under some determinate measure in the nature of the thing.

The only difference then, between one tune and another is in the degrees.

If two or more sounds be compared together in this relation, they are either equal or unequal in the degree of tune.—Such as are equal are called unisons.

The unequal constitute what we call an interval, which is the difference of time between two sounds.

Sonorous bodies we find differ in tune: 1. According to the different kinds of matter; thus a wedge of silver sounds much more acute than a wedge of gold of the same shape and dimensions, in which case the tones are proportional to the specific gravity. 2. According to the different quantities of the same matter in bodies of the same figure, a solid sphere of brass, one foot diameter, sounds acuter than one of two feet diameter; in which case the tunes are proportional to the quantity of matter. Here then are different tunes connected with different specific gravities and quantities of matter, as their immediate cause. In effect, the measures of tune are only sought in the relations of the motions that are the cause of sound, which are no way so discernible as in vibrations of chords.

In the general we find that, in two chords, all things being equal, except tension, or thickness, or length, the tunes are different; there must, therefore, be a difference in the vibrations owing to these different tensions, &c. which difference can only be in the velocity of the courses and recourses of the chords, through the spaces wherein they move to and again. Now, upon examining the proportion of the velocity and the things just mentioned, wherein it depends, it is found, to a demonstration, that all the vibrations of the same chord are performed in equal times. Hence, as the tone of a sound depends on the nature of those vibrations, whose difference we can conceive no otherwise than as having different velocities; and as the small vibrations of the same chord are performed in equal times, and it is found true, in fact, that the sound of any body, arising from any individual stroke, though it grow gradually weaker, yet continues the same tone from first to last: it follows, that the tone is necessarily connected with a certain

quantity of time, in making every single vibration; of, that a certain number of vibrations, accomplished in a given time, constitutes a certain determinate tune; for the more frequent those vibrations are, the more acute the tone; and, the slower and fewer they are, the more grave the sound, though performed in the same space of time; so that any given note of a tune is made by one certain measure of velocity of vibrations, i. e. such certain courses and recourses of a chord or string, in such a certain space of time, constitute a determinate tune.

This theory is strongly supported by our best and latest writers on music, Dr. Holder, Mr. Malcolm, &c. both from reason and experience. Dr. Wallis, who holds it very reasonable, adds, that it is evident the degrees of acuteness are reciprocally as the lengths of the chords, though, he says, he will not positively affirm that the degrees of acuteness answer the number of vibrations as their true cause: but this difference arises hence, that he doubts whether the thing has been sufficiently proved by experiment. Indeed, whether the different number of vibrations, in a given time, is the true cause on the part of the object of our perceiving a difference of tune, is a thing which, we conceive, does not come within the reach of experiment. It is enough that the hypothesis is reasonable.

TUNICA, a kind of waistcoat, or under-garment, in use amongst the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics, whence Horace calls them *popellus tunicatus*. The several sorts of the tunic were the *palmata*, the *angusticlavia*, and the *laticlavia*. The first was worn by generals in a triumph, and perhaps always under the *toga picta*; it had its name either from the great breadth of the clavi, equal to the palm of the hand; or else from the figures of palms, embroidered on it. For the other two, see the article *CLAVUS*.

It was by these three different sorts of tunicks, that the three different orders of the Roman people were distinguished in habit.

TUNICA, *Tunic*, in anatomy, is applied to the membranes which invest the vessels, and divers others of the less solid parts of the body; thus the intestines are formed of five tunics, or coats, for which see the article *INTESTINES*.

There are also five tunics, or coats, of the eye, for which see the article *EYE*.

TUNIS, a kingdom of Barbary, in Africa, once the famous republic of Carthage, but now circumscribed within narrow bounds, having Tripoli on the east, the river Gualdibarbar, which parts it from Constantina, on the west, Biledulgerid Proper on the south, and the Mediterranean sea on the north. Its extent from east to west along the coast is 200 miles; but is of unequal breadth.

The present Tunese are not the descendants of the ancient Carthaginians, but a mixture of Goths, Vandals, Moors, Arabs, and Turks, with renegadoes of all nations, being no other than a nest of desperate banditti and pirates.

The soil and climate are much the same with those of Tripoli, as is also its government. The dey is absolute; but being elected by the Turkish soldiers, is as liable to be deposed, and even murdered, as the dey of Algiers, who seldom has a long reign.

The chief employment of the inhabitants, is piracy: the Europeans, however, traffic with them in some oil, olives, dates, soap, kali, or ashes, ostrich-feathers, camels, and horses. The Jews are very numerous here, and in the coast-towns of Barbary, as their brokers. Notwithstanding the infamous original of the Tunese, they value themselves upon their nobility; and they use the Moors and other inhabitants of Africa like slaves.

TUNNAGE is used for a custom or impost, payable to the crown, for goods and merchandize imported or exported, and is to be paid after a certain rate for every tun thereof. This duty, as well as that of poundage,

was first granted for life to king Charles II. and has been continued in the same manner to his royal successors, down to his present majesty king George III.

TUNNEL-NET, a net for taking partridges, which should not exceed fifteen feet in length, nor be less than eighteen inches in breadth, or opening for the entrance.

When you have found a covey, fetch a compass and pitch the net at a good distance from them, sometimes farther, at other times nearer, according to the situation of the ground; surround them either with a natural or artificial stalking-horse, and gently drive them towards the net, not coming on them in a direct line, but by turnings and windings, and sometimes standing still, as if the horse grazed. In case they make a stand and look up, it is a sign of fear, and that they intend to take wing; stand still therefore, or retreat for a while; and when you find them quiet after a little respite, and busy in seeking after meat, you are to move nearer, and if any single partridge lies remote from the rest, he may be brought in by fetching a compass about him. The wing of the tunnel must not be pitched in a direct line, but inclining to a semi-circle.

TUNNING of Ale or Beer, a part of the process of brewing, or rather an operation which is the sequel thereof. When the beer has worked or fermented in an open vat, as long as is proper, tun it up into seasoned vessels, that is, such as have had ale or beer in them before; for if it be put into new casks, it must be made stronger than ordinary, else it will not keep so long, because the cask will imbibe the spirits, and the rest will soon become flat and vapid. It is best to tun beer just when it comes to a due fermentation, and gets a good head; for then it has the most strength to clear itself in the cask, and what works over may be put into the small beer, and must be supplied with fresh beer of the same brewing. When the beer is tunned, carry it while it works in the cask, into a good cellar, or proper place to preserve it; for if it be stirred after it has done working, it will be apt to grow stale, sour, and become ale-gar, unless it be drawn out into another cask.

TUNNY, a name given by us to the Spanish mackerel, a larger fish of the scomber kind, called by authors thynnus and arcynus, by Salvia limosa, and pelamys by Aristotle, Ælian, and the other old writers.

It is properly a species of the scomber; and is expressly named by Artedi the scomber with eight or nine fins in the hinder part of the back, rising out of a furrow; and a furrow at the place of the belly-fins.

TURBAN, or **TURBANT**, the head-dress of most of the Eastern nations. It consists of two parts, a cap, and a sash of fine linen, or taffety, artfully wound in divers plaits about the cap. The Turks call the sash turbant, whence we have formed turban. The cap has no brim, is pretty flat, though roundish at top, and quilted with cotton, but does not cover the ears. There is a good deal of art in giving the turban a fine air, and the making of them is a particular trade. The sash of the Turks turban is white linen; that of the Persians red woollen. These are the distinguishing marks of their different religions. Sophi, king of Persia, being of the sect of Ali, was the first who assumed the last colour, to distinguish himself from the Turks, who are of the sect of Omar, and whom the Persians esteem heretics. The Emirs, who pretend to be descended of the race of Mahomet, wear their turbans quite green, which was the colour wore by that false prophet. The grand seignior's turban is as big as a bushel, and so exceedingly respected by the Turks, that they scarce dare touch it. It is adorned with three plumes of feathers, enriched with diamonds and precious stones, and he has an officer on purpose to look after it. The grand vizier's turban has two plumes; so have those of divers other officers, only smaller one than another; others have only one, and others none at all. The turban of the officers of the divan is of a peculiar form.

TURBAN-SHELL, *cidaris*, in natural history, the name of a genus of the echinodermata, which are of the hemispheric or spheroidal figure, and have their name from the Latin, *cidaris*, a Persian turban, as in some degree resembling that head-dress.

TURBARY, denotes a right to dig turfs on another's ground; and it is likewise taken for the ground or place where turfs are digged, sometimes called the turfary.

TURBINATED, is a term applied by naturalists, to shells which are spiral, or wreathed, conically, from a larger basis to a kind of apex.

TURBINITÆ, fossil shells of the turbo kind, or stones found in those shells. Among the people who have objected to the shells found buried in the earth being the remains of real animals, it has been alledged by some, that these, in particular, are always of a blackish or ash-colour, when found in chalk or clay, and white from the rocks, or when they have been bedded in stone.

TURBIT Pigeon, a particular species of pigeon remarkable for its short bill, and called by the Dutch cort-bek, that is, short-beak. Moore calls it, in Latin, *columba fimbriata*: and its English name seems no other than a bad pronunciation of its Dutch one. It is a small and short-bodied pigeon, and has a beak no longer than that of a partridge; the shorter this is, the more the pigeon is esteemed: it has a short round head, and the feathers upon the breast open and reflect both ways, standing out like the frill of the bosom of a shirt. This is called by many the purle, and, the more the bird has it, the more it is esteemed. The tail and back are generally of one colour, as blue, black, red, yellow, or dun, and sometimes chequered. The flight feathers, and those of all the rest of the body, are white. They are a light nimble pigeon, and, if trained to it, will take very high flights in the manner of the tumblers. *Moore's Columbarium*.

TURBITH ROOT, is the root of a large convolvulus, growing in moist places near the sea-coasts, in the island of Ceylon, Surat, Malabar, Goa, but most plentifully in Guzarotta, from whence the greatest quantities of the roots are brought into Europe. The root is commonly about the thickness of the finger, though sometimes twice or thrice as thick, brownish on the outside, whitish within, with a white spongy woody pith: its taste is at first sweetish, afterwards acid and disagreeable.

The Indians formerly slit the roots longitudinally, and took out the woody matter. At present the roots are generally brought over pith and all, being only cut transversely into oblong pieces, which are often found to be scorched at the ends: the use of the scorching is to sear up the divided vessels, and prevent the oozing out of the resinous yellowish juice, with which the fresh roots abound. Albinus's suspicion, that this juice is designedly extracted from them, before they come to us, appears to be groundless.

Turbith-root is a moderately strong purgative: as such the root in substance was formerly given, from a scruple to half a dram, and the resin to half a scruple; but since the introduction of jalap, turbith has been rarely used.

TURBITH-MINERAL, yellow precipitate of mercury. See **MERCURY**.

TURBO, in natural history, a genus of univalve shells, with a long, wide, and depressed mouth, in some species approaching to a round shape, and in some having teeth, in others not. They all grow narrow towards the base, and are auriculated, and terminate in a very long and sharp point.

Of this genus, there are a great many elegant species; as the slender turbo, with ventricose spires, and a small round mouth, about five or six inches long; besides which, there are numerous other species, as the caterpillar-shell, telescope-shell, &c. all distinguished by their different spires, and the form of their mouths.

TURBOT, or **TURBUT**, in ichthyology, the English name of a species of pleuronectes, with the eyes on the right side, and the body smooth.

It grows to a considerable size, and is one of the most esteemed fish at table.

TURCICA-TERRA, **TURKY-EARTH**, a very fine bole or medicinal earth, dug in great plenty in the neighbourhood of Adrianople, and used by the Turks as a sudorific and astringent; and famous among them in pestilential diseases. It is sometimes brought over to us

also made up into flattish, orbicular masses of two or three drams weight, and sealed with some Turkish characters. This earth is of a somewhat lax and friable texture, yet considerably heavy, of a greyish, red colour, but always redder on the surface than within; extremely soft, and naturally of a smooth surface: it melts freely in the mouth, with a considerably strong, astringent taste. See the article *BOLES*.

TURCOISE, or **TURQUOISE**, *Turcheſia*, in natural history, an ore of copper, erroneously ranked among gems.

There are, indeed, two kinds of turcois; the one a true and genuine ore of copper: the other the bones of animals tinged to a beautiful blue colour, by having been buried in places where copper-ore has been near them.

That kind which we usually distinguish by the name of the turquoise of the old rock, and which Pliny and the ancients called callais, is a true and genuine copper-ore, and is of exactly that kind in regard to this metal, that the hæmatites is to iron; it is found in the perpendicular fissures of the strata of stone, which contain copper adhering to their sides in form of a crust, and rising into botryoide efflorescences, which sometimes stand single, and are in bigness from the size of a pea to that of a walnut; but sometimes happening to be placed close to one another, they join and form flat crusts or masses, extending, in the manner of crusts of the hæmatites, to three, four, or more inches in breadth; in these the prominent part of every tubercle appearing on the surface, the whole seems a conjunction of semi-circular bodies of a fine blue colour joined by an intermediate substance of the same nature.

This kind of the turquoise is of a very close texture and glossy surface, but very soft, and, when broken, shews the same crusted and striated texture with the hæmatites; only that the striæ are usually finer, and the plates better joined. It ferments with aqua fortis, and may be in great part dissolved by it; and on calcining, it loses all its colour, and becomes of a dirty white. This is produced in Persia, and some other parts of the East. The Germans also have a botryoide copper-ore, in some of their mines; but it is green, and much softer than the true turquoise of this kind, though this has been often produced among us also under the name of that gem.

The other turquoise is nothing more than the teeth or bones of animals, which have lain in the way of effluvia, in which copper has been contained, and by this means have acquired veins and streaks of a deep blue, which, on the whole being slightly calcined, diffuse themselves through all the substance, and give it the fine pale blue we so much admire in this gem. If the fire that diffuses this colour be a little too strong, it sends it wholly off, and leaves in place of the turquoise only a white bone. The turquoises of this last kind are common in France; there are mines of them there, and the people who work them are perfectly acquainted with the method of diffusing the colour through them. These are what are now usually worn, and, when fine, are called, by many of our jewellers, turquoises of the old rock, as well as the other. The virtues attributed to this gem are very great, but all we know of it at present is, that, like the other bodies that contain copper, it is a violent emetic, and not fit to be received into practice.

Composition of hard Glass, or Paste, resembling the TURQUOISE Stone.

“Take of the compositions for blue glass, or paste N^o. 7 or 8, being those resembling the eagle marine, ten pounds; of calcined bone, horn, or ivory, half a pound. Powder and mix them well; and then fuse them in a moderate heat, till they be thoroughly incorporated.”

TURDUS, in ornithology, a genus of birds, the beak of which is of a conic form, and straight, only somewhat bent on the upper part, and has no membrane at the base: the tongue is lacerated and emarginated.

Under this genus are comprehended the black-bird, thrush, red-wing, &c.

TURDUS, in ichthyology, the name by which authors call the green labrus, with a blue line on each side; a very beautiful fish, from eight to fourteen inches in length, and considerably thick in proportion.

TURF, a blackish, sulphureous earth, used in several parts of England, Holland, and Flanders, as fuel.

In Flanders, their turf is dry or pared from off the surface of the earth, and cut in form of bricks. — The sedge, or species of grass growing very thick on the turf earth, contributes greatly, when dry, to the maintenance of the fire.

The Dutch take their turf from the bottom of the dykes or canals which run across most of their lands; by which means they not only supply the defect of wood, which is very great in most of the United Provinces, but also keep their dykes clear and navigable: this turf earth is very black. As they take it up from the bottom of the dykes, they spread it about the edges, of such a thickness, as that it may be reduced to three inches when moderately dried. — In this condition they cut it into pieces of turfs seven or eight inches long, and three broad, and, to complete the drying, lay them up in heaps, and at last in stacks.

In the north of England, Scotland, &c. turf is dug out of soft, moist, rotten earth, called peatmoſs. — They dig horizontally from the surface, to the depth of about four foot, with a spade, which at once fashions and takes them out in parallelopipeds nine or ten inches long, and three square; which are spread on the ground to drain as fast as dug; and then set up an end three or four against each other, for the wind to blow through them; and at last they are stacked or housed. — The pits or dykes in a few years fill up again, and afford a fresh crop.

TURFING-SPADE, among husbandmen, is an instrument used to under cut the turf, after it is marked out with a trenching-plough.

TURGESCE, **TURGESCE**, a swelling, or growing bloated.

TURIONES, among herbalists, denotes the first young tender shoots, which plants annually put forth.

TURKEY, *Meleagris*, in ornithology, a genus of birds, the anterior part of the head of which is covered with a fleshy pendulous substance; the sides of the head also, and the throat, are covered with a papillous fleshy matter, and there is a longitudinal fleshy crest, of a reddish, bluish, or purplish colour, and a soft substance. This is a large, but unwieldy bird; the head is strangely covered and ornamented with a pendulous, soft, fleshy substance, as already observed; the eyes are small, but bright and piercing; the wings are moderately long, though not at all formed for supporting so large a bulk in long flights; they have each twenty-eight long feathers; the tail is long and large, the legs moderately long, and very robust. There is but one known species of this genus.

TURKEY, a considerable modern empire, containing several rich and extensive countries. In Europe the Turks possess Romania, Bulgaria, Bessarabia, Budziack, Moldavia, Walachia, Servia, a part of Sclavonia and Hungary, Croatia, Bosnia, Dalmatia, Ragusa, ancient Greece, and in general the numerous islands on its coast, or those of the Archipelago, with Ockzakow Tartary, Tartary the Less, and Crim-Tartary; which three last countries are tributaries or allies to the Ottoman Porte.

In Asia they are masters of Anatolia, or Asia Minor, the islands on its coasts or in the Levant, Syria, Phœnicia, Palestine or Judea, Arabia, Diarbeck or Mesopotamia, Yerack or Chaldea, Curdistan or Assyria, Armenia Major, now Turcomania, part of Georgia, Mingrelia, and Circassia. Lastly, in Africa they are possessed of Egypt, besides innumerable tributaries in that part of the world; yet all these considerable advantages are lost to the Turks, through their natural indolence; for they are above applying to trade or manufactures, these they leave to despised Christians. The merchandize of other countries are carried to them in foreign bottoms, as are also their own produce and manufactures: so that the

only

only advantage which they reap is from the duties of export and import.

The number of Christians exceeds that of Mahometans, especially in European Turkey, where they are allowed the free exercise of their religion, in reward of their labour and industry, which indeed are the main support of this empire; and they are never forced into the Turkish armies, but left to follow their employments, whilst the Turkish gentry take the defence of their country, and the business of foreign conquests entirely upon themselves.

The goods chiefly exported from Turkey are raw silk, carpets, goats-hair, wool, mohair, cotton, woollen yarn, dimities, chagrins, cordouans, coffee, turpentine, terra lemnia, rhubarb, gum arabic, opium, cochinchina, and other drugs; with wine, oil, figs, raisins, currants, dates, &c.

The Ottoman emperor or grand signior is absolute, and the throne hereditary down from the grand impostor Mahomet: for though his guards the Janizaries often depose him as they please, yet they prefer the nearest relation to the imperial dignity. The emperor indeed has an absolute authority over the inhabitants of the seraglio, his bashaws, and officers, as well as over his Christian subjects; yet the Turkish gentry, who have no places at court, nor dependence on the sovereign, enjoy their liberties and properties, paying no taxes, the attempt to impose which, or the least innovation in their customs, would endanger the deposing of the emperor.

His bashaws, governors, and officers of state, with the inhabitants of the seraglio, and even the Janizaries, are children of Christian parents, either taken in war or purchased from Georgia or Circassia, who from their infancy are trained up in the military discipline, and the Mahometan religion.

The Turkish militia is very numerous; but the flower of all and their chief dependence are the Janizaries, of which 25000 are always in pay. Other troops bear this name; but they are not enrolled with the former, and may amount to about 100,000 in the whole Ottoman empire. The sedar or commanding officer of the Janizaries in every province takes money of the Turks for being entered into this body; so that by this means each of them purchases the privilege of committing any outrages with impunity, and being screened from justice, since a Janizary is accountable to none but his officers for any violences which he may commit. The general of this militia is called aga of the Janizaries, and is always chosen out of the royal chamber of the seraglio; because, as it is an office of great importance, it is thought necessary to be entrusted to one whose education and preferment have made him a creature of the court.

The Turkish cavalry or spahis, being trained up in warlike exercises like the infantry or Janizaries, compose a formidable body; besides these, there are great bodies of forces in every province, which constitute their numerous armies; but their numbers have often occasioned their defeat, as they charge in too great confusion. The renegado bashaw Count Bonneval, however, having introduced the French discipline among them, they made a good advantage of this in the recovery of the vast extent of country south of the Danube.

The Turks, though their dominions lie on several seas, with many commodious harbours, are but weak in maritime forces, chiefly owing to their neglect of navigation and foreign commerce: so that they are in great want of good mariners, skilful pilots, and experienced officers; those belonging to the grand signior scarcely knowing how to use the compass.

The revenues of the grand signior are partly fixed, and partly casual. The fixed are those which arise from the customs, or poll-tax imposed on the Jews and Christians, the excise on all the produce of the soil, and the annual sums from the tributaries, besides five millions returned from Egypt.

The casual revenues consist in inheritances, the prince being heir to the great and small to whom he gave pensions; and also to the foldiers, when they die without children: if only daughters are left, he receives two

thirds of the estate. The spoils of the great men of the Porte and the bashaws rise to an immense sum: very often the grand signior does not stay for their dying a natural death, or give them time to conceal their treasure; but their gold, silver, jewels, and heads, are at once carried to the seraglio; besides, such as the sultan gratifies with any post of consequence, are indispensably obliged to make him presents.

The established religion throughout Turkey is Mahometism, but Christians and Jews are tolerated among them.

TURLUPINS, in church history, an infamous sect, which made its appearance in France in the fourteenth century, and the reign of Charles V. Their principal scene was in Savoy and Dauphiny.

They taught, that, when a man is arrived at a certain state of perfection, he is freed from all subjection to the divine law. They allowed of no prayer to God, but mental. They often went naked, and said, we ought not to be ashamed of any parts which nature has given us. Notwithstanding these impious extravagances, they affected great airs of spirituality and devotion, the better to insinuate themselves into the good opinion of the women. It is not easy to find the true reason of their name. Vignier thinks, they were called Turlupins, because they usually abode in places exposed to wolves, *lupis*. They affected to call themselves "The fraternity of the poor."

The Turlupins were prosecuted by order of the government. Their books and cloaths were burnt at Paris; and Joan Dabentonne, and another woman, who were the principal preachers of this sect, were burnt alive.

TURMERIC, a small tuberous knotty root, brought from the East Indies; externally greyish, internally of a deep lively yellow or saffron colour, which by age changes more and more towards a red. Two sorts are mentioned by authors, one longish, the other roundish: only the first is met with in the shops.—Turmeric has a slight, aromatic, and not very agreeable smell; and a bitterish somewhat warm taste. It readily gives out its active matter both to aqueous and spirituous menstrua: to the former it communicates its own deep yellow, to the latter a fine yellowish red tincture. In distillation with water, it yields a small quantity of a gold coloured essential oil, of a moderately strong smell and a pungent taste: the remaining decoction, inspissated, leaves a bitterish, considerably saline mass. Rectified spirit elevates little or nothing of its virtues; all the active parts of the root being left behind in the inspissated extract, which is moderately warm, and bitter, and not a little nauseous.

This root is said to be in general use in the Eastern countries, both for the colouring and seasoning of food, and as a medicine: it is accounted one of the most effectual remedies in obstructions of the viscera and mesentery, which are there frequent; in uterine disorders, difficulties of urine, and affections of the kidneys. Among us it has been employed also as a deobstruent, and esteemed by some a specific in the jaundice: the dose in substance is from a scruple to a dram; in decoction or infusion, twice as much. It tinges the urine of a deep yellow colour.

The spirituous tincture of turmeric applied upon warm marble, gives a durable red stain. Woollen cloth, impregnated with a solution of alum and tartar, acquires on being boiled with the watery decoction, an elegant, but not very durable orange yellow or gold coloured dye. It is rarely made use of by the dyers on account of its price and the perishableness of its colour.

TURN, in law, a court held twice a year, viz. within a month after Easter and Michaelmas, respectively, by the sheriff of every county.

By magna charta, sheriffs were restrained from holding pleas of the crown; but they are still judges of record, and may take indictments and presentments, and inquire of all treasons and felonies by the common law, as well as the lowest offences against the king; common nuisances, annoyances, purprestures, &c. Also of persons selling corrupt victuals, breaking the assise of ale and beer,

beer, or keeping false weights, &c. disturbers of the peace and barretors, &c. and may amerce for offences, &c.

TURNADO, or **TORNADO**, a wind which on some coasts blows all night from the shore.

TURNAMENT, or **TOURNAMENT**, a martial sport, or exercise, which the antient cavaliers used to perform to shew their bravery and address.

The first tournaments were only courses on horseback, wherein the cavaliers tilted at each other with canes, in manner of lances; and were distinguished from jousts, which were courses or careers, accompanied with attacks and combats with blunted lances and swords.

Others say, it was a tournament when there was only one quadril or troop; and that where there were several to encounter each other, it was a joust.—But it is certain the two became confounded together in process of time; at least we find them so in authors.

The prince who published the tournament, used to send a king at arms with a safe-conduct, and a sword to all the princes, knights, &c. signifying, that he intended a tournament and a clashing of swords, in the presence of ladies and damsels: which was the usual formula of invitation.

They first engaged man against man, then troop against troop; and after the combat the judges allotted the prize to the best cavalier, and the best striker of swords; who was, accordingly, conducted in pomp to the lady of the tournament; where, after thanking her very reverently, he saluted her, and likewise her two attendants.

These tournaments made the principal diversion of the thirteenth and fourteenth centuries. Munster says, it was Henry the Fowler, duke of Saxony, and afterwards emperor, that first introduced them; but it appears from the chronicle of Tours, that the true inventor of this famous sport, was one Geoffry, lord of Preuilli, about the year 1066.

From France they passed into England and Germany.—The *Historia Byzantina* tells us, that the Greeks and Latins borrowed the use thereof from the Franks; and we find mention made of them in Cantacuzenus, Gregorias, Bessarion, and others of the late Greek authors.

Budæus derives the word from *Trojana agmina*; others from *Trojamentum*, *quasi ludus Trojæ*. Menage deduces it from the Latin, *tornensis*, or the French, *tourner*, in regard the combatants turned and twisted this way and that. M. Paris calls them in Latin, *hastiludia*; Neubrigensis, *meditationes militares*; others *gladiatura*, others *decursiones ludicæ*, &c.

Pope Eugenius II. excommunicated those who went to tournaments, and forbid them burial in holy ground.—King Henry II. of France died of a wound received at a tournament.—One Chiaoux, who had assisted at a tournament under Charles VIII. said very wisely, “If it be in earnest, it is too little; if in jest, too much.”

It is to the exercise of tournaments that we owe the first use of armories: of which the name blazonry, the form of the escutcheons, the colours, principal figures, the mantlings, label, supporters, &c. are undeniable evidences.

In Germany, it was anciently a custom to hold a solemn tournament every three years, to serve as a proof of nobility. For the gentleman who had assisted at two, was sufficiently blazoned and published; that is, he was acknowledged noble, and bore two trumpets by way of crest on his tournament casque.—Those who had not been in any tournaments, had no arms, though they were gentlemen.

TURNERA, in botany, a genus of plants; the empalement of the flower is funnel-shaped, having an oblong, cylindrical, angular tube, cut into five segments. The flower has five heart-shaped plain petals, with narrow tails, which are inserted in the tube of the empalement; it has five awl-shaped stamina, which are shorter than the petals, inserted in the empalement, terminated by acute pointed erect summits, and a conical germen, supporting three slender styles, crowned by many hairy pointed stigmas. The germen afterward turns to an

oval capsule with one cell, which opens at the top with three valves, and contains several oblong obtuse seeds.

There are two species of this plant, and both natives of America. The first sort of which rises with a shrubby stalk to the height of eight or ten feet, sending out branches on every side the whole length, garnished with narrow, spear-shaped, hairy leaves, terminating in acute points, sawed on their edges; these, when rubbed, emit a disagreeable odour. The flowers grow from the foot-stalks of the leaves, to which they fit very close, having two pretty large leafy appendages to their empalements. The flowers are of a pale yellow colour, composed of five large oval petals, whose tails are twisted and join; these are succeeded by short tubular capsules, having one cell, which opens at the top with three valves, which turn back, and let out the seeds.

The second sort has a shrubby stalk like the first, and rises to near the same height. The branches of this are slender, and stiffer than those of the former. The leaves are oval, spear-shaped, rough on their upper side, and of a lucid green; their under side has many strong veins, and is of a lighter colour; they are sawed on their edges, and have longer foot stalks than those of the first species. The flowers sit close upon the foot-stalks of the leaves, in like manner as the former; but the flowers are larger, and of a brighter yellow than those. These differences remain constant, and never alter when raised from seeds; so that from near thirty years experience in sowing the seeds, I may pronounce them different species.

The plants are easily propagated by sowing their seeds on a hot-bed early in the spring; and when the plants are come up two inches high, they should be transplanted into small pots, and plunged into a hot-bed of tanner's bark, observing to water and shade them until they have taken root; after which they must be treated like other tender plants from the same countries. The seeds of these plants will often fall into the pots which are placed near them in the stove, which will grow, and soon furnish plants enough, after a person is once possessed of them. As they are too tender to live in the open air in England, they must be placed in the bark-bed in the stove, where, during the winter season, they must be kept warm, and frequently watered; but in the summer-season they must have a great share of air, otherwise they will draw up tender, and not produce many flowers.

When the plants are grown pretty large, they may be treated more hardily, by placing them in the dry stove, where, if they are kept in a moderate degree of heat, they will thrive and flower very well. Those who would save the seeds of these plants, must watch them carefully, because, when they are ripe, they soon scatter if they are not gathered.

These plants produce their flowers great part of the year, if they are kept in a proper degree of warmth; so that there are some of the flowers in beauty for at least nine or ten months, which renders the plants more valuable. *Miller's Gard. Diet.*

TURNING, a branch of sculpture, being the art of fashioning hard bodies, as brass, ivory, wood, &c. into a round or oval form, in a lathe.

Turning is performed by putting the substance to be turned upon two points as an axis, and moving it round on that axis; while an edge-tool, set steady to the outside of the substance in a circumvolution thereof, cuts off all the parts which lie farther off the axis, and makes the outside of that substance concentric to the axis. See the article **LATHE**.

The invention of turning seems to have been very ancient. Some, indeed, to do honour to the age, will have it brought to perfection by the moderns; but, if what Pliny and some other ancient authors relate, be true, that the ancients turned those precious vases enriched with figures and ornaments in relieve, which we still see in the cabinets of the curious, it must be owned that all that has been added in these ages, makes but a poor amends for what we lost of the manner of turning of the ancients.

The lathe, or principal instrument used in turning, is composed of two wooden cheeks, or sides parallel to the horizon, having a groove, or opening between them;

perpendicular to these are two pieces, called heads or puppets, made to slide between the cheeks, and to be fixed down at any point at pleasure: these have two points or center pins, between which the piece to be turned is fastened by the help of a screw. There is also a square piece of wood called a rest, which bears up the tool, and keeps it steady. The piece is turned round backwards and forwards, by means of a string put round it, and fastened above to the end of a pliable pole, and below to a treddle or board moved by the foot. This is the common lathe; but there is another used in hollow turning &c. very different from it.

This lathe is composed like the other of two cheeks, and has also two heads fitted to slide between them; but has no pole, being turned by means of a wheel and a pulley. The pulley is fastened on a kind of spindle called a mandrel, one end of which is pointed, and received into the center of the back screw, which goes through one of the heads; and near the other end, called the verge, it moves in a piece called the collar; the end of the mandrel passes through the collar, and on it the piece to be turned is fastened. These descriptions will be rendered abundantly more easy from the two perspective views on plate CXXXIII. which represent both these kinds of lathes in so conspicuous a manner, that a full idea of both may be easily attained.

Fig. 1. is the lathe used by hollow turners, &c.

1. The lathe. 2. The groove. 3, 3. The heads or puppets. 4. The pulley. 5. The mandrel. 6. The collar. 7. The back-screw. 8. The rest. 9. The wheel. 10. The crank. 11. The treddle.

There are several kinds of mandrels, adapted to the different kinds of work; as

Flat mandrels, which have three or more little pegs or points, near the verge, and are used for turning flat pieces on.

Pin mandrels, which have long wooden shanks, to fit into round holes in the work to be done.

Hollow mandrels, which are hollow of themselves, and used for turning hollow work.

Screw mandrels, which are used in turning screws.

There are a great variety of other instruments used in turning, as chisels and gouges of different kinds, perspective views of most of which are represented in the figure. Thus, 12. Is a tool called a holdfast. 13. A point tool. 14. A broad chisel called a firmer.

Fig. 2. is a perspective view of the common lathe.

1. The lathe. 2, 2. The heads or puppets. 3. The pole. 4. The treddle. 5, 5. Screws which fix the rest at a proper height. 6, 6. The rest. 7. The back-screw.

The workman stands, or is seated in his lathe, having one of his feet on the treddle to give the motion, which must be very moderate and equal; he places his tool on the rest, and approaches the edge of it gently to the piece, performing his work gradually, without leaving any ridges; and, when he meets with a knot, he must go on still more gently, otherwise he would be in danger both of splitting his work, and breaking the edge of his tool.

The two perspective views on the plate will give a better idea of the nature of turning, than is possible to be conveyed by words. The first figure shews the nature of hollow turning, and the second that for common work.

TURNING-EVIL, in cattle, a disease that causes them frequently to turn round in the same place. It is also called the sturdy. The common remedy, recommended by Mr. Markham, is to throw the beast down, and bind him; then to open his skull, and take out a little bladder, filled with water and blood, which usually lies near the membrane of the brain, and then gradually heal the wound.

TURNIP, or **TURNEP**, in botany, an esculent plant, of which there are three species enumerated by Miller. The first is the turnip which is commonly cultivated in the fields, of which there are the following varieties, viz. the round red or purple topped turnip, the green topped turnip, the yellow turnip, the black rooted turnip, and the early Dutch turnip. The last sort is commonly sown early in the spring, to supply the markets in May and June, but is never cultivated for a general crop.

The red rooted turnip was formerly more cultivated in England than at present; for since the large green topped turnip has been introduced, all the skilful farmers prefer it to the other sorts; the roots of the green will grow to a large size, and continue good much longer than the other sorts. The next to this is the red or purple topped turnip, which will also grow large, and is extremely good for some time; but the roots of this will become stringy much sooner than those of the green topped. The long rooted turnip, the yellow turnip, and the blackish rooted turnip, are now rarely cultivated, in England, neither of them being so good for the table or for feed, as the red and green topped turnip, though there are some few persons who sow them for the sake of variety.

The French turnip is not much cultivated in England, but in France and Holland they are in great esteem, especially for soups; their roots being small, are boiled whole in the soup, and so served up to the table; these must be used while they are young, otherwise they will become rank and stringy.

These are supposed to be only varieties, which have accidentally been obtained from seeds, therefore I have not enumerated them as distinct species; but yet I am certain they are constant, where care is taken in the saving of their seeds, not to suffer any mixture to stand for seeds: I have sown of three or four sorts several years, and have always found them retain their differences; however, it is not easy to determine if some of these were not by culture first obtained from seeds of the common white turnip. The yellow turnip seems most unlikely to have been an accidental variety, for I have never known this alter, and the roots are yellow within, whereas all the other have white flesh, notwithstanding their outsides are of very different colours.

The long rooted turnip is, I think, a distinct species, the form of the root, and its manner of growth being totally different from the other sorts. I have seen these roots as long as those of the parsnip, and nearly of the same shape; these run deep into the ground, so are unfit for feeding of cattle; and unless they are used very young, become strong, so not proper for the table, which has occasioned their being rejected of late years.

The green topped turnip grows above ground more than any of the other, which renders it preferable for feeding of cattle; and being the softest and sweetest root when grown large of any of the kinds, is most esteemed for the table; but in very severe winters they are in greater danger of suffering by frost, than those whose roots lie more in the ground, especially if they are not covered by snow; for when they are frequently hard frozen and thawed, it causes them to rot sooner than those whose flesh is less tender and sweet. I have seen the roots of this sort, which were more than a foot diameter, boiled, and were as sweet and tender, as any of the smallest roots.

Turnips delight in a light, sandy, loamy soil, which must not be rich; for in a rich soil they grow rank and are sticky, but if it be moist they will thrive the better in summer, especially in fresh land, where they are always sweeter than upon an old worn-out or a rich soil.

The common season for sowing of turnips, is any time from the beginning of June to the middle of August, or a little later; though it is not advisable to sow them much after, because, if the autumn should not prove very mild, they will not have time to apple before winter, nor will the roots of those which are sown after the middle of July, grow very large, unless the frost keeps off long in autumn. But, notwithstanding this is the general season in which the greatest part of turnips are sown in the country, yet, about London, they are sown successively from March to August, by those who propagate them to supply the markets with their roots; but there is a great hazard of losing those which are sown early in the year, if the season should prove dry, by the fly, which will devour whole fields of this plant while young; so that where a small quantity for the supply of a family is wanted, it will be absolutely necessary to water them in dry weather; and where a person sows those seeds in April and May, it should always be upon a moist soil, otherwise they seldom come to good, the heat

heat of the weather at that season being too great for them upon a dry soil; but those which are sown towards the middle or latter end of June, commonly receive some refreshing showers to bring them forward; without which, it is very common to have them all destroyed.

These seeds should always be sown upon an open spot of ground; for if they are near hedges, walls, buildings, or trees, they will draw up, and be very long topped, but their roots will not grow to any size.

They are sown in great plenty in the fields near London, not only for the use of the kitchen, but for food for cattle in winter, when there is a scarcity of other food; and this way is become a great improvement to barren sandy lands, particularly in Norfolk, where, by the culture of turnips, many persons have doubled the yearly value of their ground.

The land upon which this seed is sown, should be ploughed in April, and twy-fallowed in May, that is, once more ploughed and twice well harrowed, and made very fine; then the seed should be sown pretty thin; for it being small, a little will sow a large piece of ground; one pound is the common allowance for an acre of land. The seed must be harrowed in as soon as it is sown, with a short-tinned harrow, and the ground rolled with a wooden roll, to break the clods, and make the surface even. In ten days or a fortnight after sowing, the plants will come up; at which time, if the season should prove dry, they will be in great danger of being destroyed by the fly; but if it so happen, the ground must be sowed again, for the seed being cheap, the chief expence is the labour; but the ground should be first harrowed to loosen it, especially if it is stiff land.

When the plants have got four or five leaves, they should be hoed to destroy the weeds, and to cut up the plants where they are too thick, leaving the remaining ones about six or eight inches asunder each way, which will be room enough for the plants to stand for the first hoeing; the sooner this is performed, when the plants have four leaves, the better they will thrive; but in the second hoeing, which must be performed about a month after the first, they should be cut up, so as that the remaining plants may stand fourteen or sixteen inches distance, or more, especially if they are designed for feeding of cattle; for where the plants are allowed a good distance, the roots will be proportionably large; so that what is lost in number, will be over-gained by their bulk, which is what I have often observed. But in such places where they are sown for the use of the kitchen, they need not be left at a greater distance than ten inches or a foot, because large roots are not so generally esteemed for the table.

It is not many years since the practice of sowing turnips for feeding of cattle, has been of general use; how it happened that this improvement should have been so long neglected in every part of Europe, is not easy to determine, since it is very plain, that this piece of husbandry was known to the ancients. For Columella, in treating of the several kinds of vegetables which are proper for the field, recommends the cultivating *rapa* in plenty; because, says he, those roots which are not wanted for the table, will be eaten by the cattle: yet this plant was not much cultivated in the fields till within the last sixty or seventy years; nor is the true method of cultivating turnips yet known, or at least not practised, in some of the distant counties of England, at this time. For in many places the seed is sown with barley in the spring, and those plants which come up, and live till the barley is cut, produce a little green for the sheep to pick up, but never have any roots. In other places, where the turnip seed is sown by itself, the method of hoeing them is not understood; so that weeds and turnips are permitted to grow together; and where the turnips come up thick in patches, they are never thinned, so that they draw up to have long leaves, but never can have good roots, which is the principal part of the plant, therefore should be chiefly attended to.

The general method now practised in England, for cultivating this plant in the fields, is the same as is practised by the farming gardeners, who supply the London markets with these roots, and is the same as before directed. But it is only within the compass of a few

years, that the country people have been acquainted with the method of hoeing them; so that the farmers formerly employed gardeners, who had been bred up in the kitchen gardens, to perform this work; but it is now performed by many country labourers, by which means that practice is lost to the kitchen gardeners; the labourers doing it much cheaper.

There has also been another method practised very lately, by some very curious farmers, in cultivating of turnips, which is by sowing the seed in rows, with the drill-plough. In some places the rows are sown three feet asunder, in others four, in some five, and some six. The latter has been recommended by some, as the most proper distance; and although the intervals are so large, yet the crop produced on an acre has been much greater than upon the same quantity of land, where the rows have been but half this distance; and upon all the fields which have been tilled, the crops have greatly exceeded those which have been hand-hoed. The late lord viscount Townshend was at the expence of making the trial of these two different methods of husbandry, with the greatest care, by equally dividing the same fields into different lands, which were alternately sown in drills, and the intermediate lands in broad cast. The latter were hoed by hand, in the common method, and the other cultivated by the hoeing-plough; and when the roots were fully grown, his lordship had an equal quantity of land, which had been sowed in the different methods, measured, and the roots drawn up and weighed; those roots which had been cultivated by the plough, were so much larger than the other, that the crop of one acre weighed a ton and half more than that of an acre in the other husbandry.

But when the turnips are sown in drills, they will require to be hoed by hand, to separate and cut out the plants, where they are too near together in the rows; as also to cut up the weeds between the plants, where the plough cannot reach them. If this is carefully performed, the ploughing of the intervals will encourage the growth of the roots, by thus stirring of the ground, and make it much better prepared for the crop of barley, or whatever else is sown the following spring. This method of culture may be supposed to be more expensive than that commonly practised, by those unacquainted with it; but those who have made trial of both, find the horse-hoeing to be much the cheapest, and by far the best. For the country people, who are employed in hand-hoeing of turnips, are very apt to hurry over their work, so that half the weeds are left growing, and the plants are seldom singled out so well as they should be; nor are they curious enough to distinguish the charlock, which is one of the most common weeds in arable land, from the turnips; so that about the middle of September, it is very common to see the fields of turnips full of the yellow flowers of the charlock. Now, in the horse-hoeing, all the weeds in the intervals will be entirely destroyed; so that if a few plants in the rows of turnips should be overlooked, they may be easily drawn when they appear visible, and by this method the land will be sooner and better cleaned from weeds.

The greatest evil which attends a crop of turnips, is that of their being destroyed by the fly, which usually happens soon after the plants come above-ground, or while they are in the seed-leaf; for, after they have put out their rough leaves pretty strong, they will be past this danger. This always happens in dry weather; so that, if there should be rain when the turnips come up, they will grow so fast, as to be in a few days out of danger from the fly; and it hath been found, that those, which have been sown in drills, have escaped the fly much better than those sown in broad cast; but, if foot is sown along the surface of each drill, it will be of great service to keep off the fly, and a small quantity of it will be sufficient for a large field, where the drills only are to be covered.

Another danger of the crops being destroyed is from the caterpillars, which very often attack them, when they are grown so large as to have six or eight leaves on a plant. The surest method of destroying these insects, is to turn a large parcel of poultry into the field, which should be kept hungry, and turned early in the morning

into the field; these fowls will soon devour the insects, and clear the turnips. To this evil the turnips, which are sown in drills, are not so much exposed; for as the ground between the rows will be kept stirred, the plants will be kept growing, so will not be in danger of suffering from these insects, for the parent insects never deposit their eggs upon any plants which are in health; but as soon as they are stunted, they are immediately covered with the eggs of these insects; and this holds in general with vegetables as with animals, who are seldom attacked by vermin when they are in perfect health; whereas, when they become unhealthy, they are soon overspread with them; so that it is the disease which occasions the vermin, and not the vermin the disease, as is commonly imagined.

When the turnips are sown in drills, it will be the best way to plough between every other row at first, and some time after to plough the alternate intervals, by which method the plants will receive more benefit from the often stirring the ground than they would do, if all the intervals were hoed at one time; and plants will be in less danger of suffering from the earth being thrown up too high on some rows, while others may be left too bare of earth; but, when the earth has been thrown up on one side of the drill, it may be turned down again soon after the next interval is ploughed. This alternate moving of the earth will prepare the ground very well for the succeeding crop, and greatly improve the turnips; but, as the plough cannot well be drawn nearer to the drills than two or three inches, the remaining ground should be forked to loosen the parts, and make way for the fibres of the roots to strike out into the intervals; otherwise, if the land is strong, it will become so hard in those places which are not stirred, as to stint the growth of the turnips. This may be done at a small expence; a good hand will perform a great deal of this work in a day, and, whoever will make the trial, will find their account in practising it, especially on all strong land, where the turnips are much more liable to suffer from the binding of the ground, than they will be on a loose soil; but yet, in all sorts of ground, it will be of great service to practise this.

When the ground is thus stirred in every part, one ploughing will be sufficient, after the turnips are eaten, for the sowing of barley, or any other crop; so that there will be an advantage in this, when the turnips are kept late on the ground, as will often be the case, especially when they are cultivated for feeding of ewes, because it is often the middle of April before the ground will be cleared; for late feed in the spring, before the natural grass comes up, is the most wanted, where numbers of sheep or ewes are maintained, and one acre of turnips will afford more feed than fifty acres of the best pasture at that season.

In Norfolk and some other counties they cultivate great quantities of turnips for feeding of black cattle, which turn to great advantage to their farms, for hereby they procure a good dressing for their land; so that they have extraordinary good crops of barley upon those lands, which would not have been worth the ploughing, if it had not been thus husbanded.

When the turnips are fed off the ground, the cattle should not be suffered to run over too much of the ground; for, if they are not confined by hurdles to as much as is sufficient for them one day, the cattle will spoil three times the quantity of turnips as they can eat, so that it is very bad husbandry to give them too much room; therefore the hurdles should be every day removed forward, and if the turnips are drawn out of the ground before the cattle or sheep are turned into the new inclosure, there will be less waste made, for they will then eat up the whole roots; whereas, if they are turned upon the turnips growing, they will scoop the roots, and leave the rinds, which being hollow, the urine of the sheep will lodge in them; so that, when they are forked out of the ground, the sheep will not eat any of those roots which are thus tainted.

I cannot omit taking notice of a common mistake, which has generally prevailed with persons who have not been well informed to the contrary, which is in relation to the mutton which is fatted with turnips, most

people believing it to be rank and ill tasted; whereas it is a known fact, that the best mutton this country affords is all fatted on turnips, and that rank mutton, whose fat is yellow, is what the low marshy lands of Lincolnshire, and other rank pastures, produce.

In order to save good turnip seeds, you should transplant some of the fairest roots in February, placing them at least two feet asunder each way, observing to keep the ground clear from weeds, until the turnips have spread so as to cover the ground. When they will prevent the weeds from growing; when the pods are formed, you should carefully guard them against the birds, otherwise they will devour it, especially when it is near ripe; at which time you should either shoot the birds as they alight upon the seed, or lay some bird-limed twigs upon it, whereby some of them will be caught; and, if they are permitted to remain some time, and afterwards turned loose, they will prevent the birds from coming thither again for some time, as I have experienced. When the seed is ripe it should be cut up, and spread to dry in the sun; after which it may be threshed out, and preserved for use.

There have been many receipts for preventing the fly taking turnips, but few of them deserve notice, therefore I shall only mention two or three which I have seen tried with success. The first was steeping the seeds in water with flour of brimstone mixed, so as to make it strong of the brimstone: another was steeping it in water with a quantity of the juice of horse-aloes mixed, both which have been found of use. The sowing of foot or tobacco dust over the young plants, as soon as they appear above ground, has also been found very serviceable: in short, whatever will add vigour to the young plants, will prevent their being destroyed by the fly, for those never attack them, till they are stunted in their growth. *Miller's Gard. Dict.*

Mr. Lisle is inclined to think, that the best way to manage turnips, the seed of which, says he, is impatient of growth, and apt to burst in too much wet, as also to corrupt, if the ground be so dry as only to give it a damp, but not wet enough to set it on growing, is, first to harrow the ground fine, after it has been brought to a perfect tilth by ploughing, then to roll it with a roller big enough to break the little clods, if any such remain, and so let it lie till the next rain; then, the ground being mellow, to sow the seed, and harrow it in with short-tinned harrows, which may not open the ground too deep, nor bury the seed; then roll it again with a one-horse roller, in order to keep the moisture in the ground as deep as the seed may be: for the surface of the earth must not be dried before the seed can strike root, which may be in twice twenty-four hours; and yet that surface must be so fine, and so lightly compressed, that the seed may spear through it. He takes the mystery, as he calls it, of the success or miscarriage of a crop of turnips to consist in these four things, viz. first, in the seed's not lying too deep; secondly, in its not lying too wet, which it cannot easily do if harrowed in shallow, for the surface of the earth is soon dry; thirdly, in its not lying too dry; and fourthly, in its lying in a fine bed. In another place, he tells us, that his gardener affirmed to him, that he had found turnip seeds, which had been dropped by accident and covered over with earth in digging, fresh and good a year after, when the earth was turned back again, and that it has then grown and produced good turnips. The reason is, that every seed which is buried so deep as not to be affected by the changes in the air, may remain in a sound state, and in a fit condition to vegetate, for many years, as hath been evinced by numbers of instances.

Mr. Duhamel advises after the two first hoeings a slight ploughing all over the field, with a plough that has no fins to the share, as a speedier and cheaper way to thin the plants: the turnips will not require any farther care. They will have attained their full size in October, before the frosts come, and should then be taken up, stripped of their leaves, which may be given to cattle, and laid upon hurdles in a dry place, with a layer of dry sand between each layer of turnips, which may be thus piled up, and which will keep very well in this condition, for the food of cattle during the winter. In Norfolk, they stow

sow them in their barns, when intended for fattening of bullocks.

A dry season is the best for hoeing turnips, because neither the weeds nor the turnips hoed up then will be so apt to grow again: and Mr. Lisle supposes that care should be taken to hoe up those that are deepest rooted in the earth, and to leave those that grow upon, and almost out of it, without much regarding their size; because those which lie on the ground, and have room to grow, will soon become the largest.

Some sow turneps on their flax and hemp grounds, at the same time as they pluck up those plants, and the seed is pretty well buried by the stirring thereby given to the earth. Others give their corn stubble only a slight plowing after harvest, then sow the turnips very thin, and harrow in the seed. These methods do very well when the ground is in good tilth. Others again, sow late turneps, merely for the sake of their leaves, which they use as green feed, when they are about a foot high; and in this case they sow the seed very thick.

An easy way to have two growths of turnips in the same field, is to sow seed of the last gathering, and seed that is two years old; for this last is longer before it rises, than the new: and an advantage attending this method, is, that the turnips, by rising at different times, will have the better chance to escape the fly, or grub, which sometimes destroy them entirely: for it has been observed, that these flies often come suddenly in great swarms, and eat up the turnips as fast as they rise; and that they sometimes disappear as suddenly; so that the turnips which rise a few days after, in a neighbouring field, are not at all injured by them: consequently, when the turnips of the same field rise at different times, one or other may escape the ravage of these insects; for they destroy them only while in their seed leaf.

The worm to which turnips are very liable may be guarded against, at least in a great measure, as Mr. Lisle informs us, by liming the ground. This will also render them much sweeter than they would otherwise be: and we are of opinion that fresh slaked lime strewed over the ground when the turnip seed is sown, will contribute greatly to preserve the young plants from the fly. It is to the worm lodged in the root of the turnip, perhaps engendered from the egg of the fly, that Mr. Lisle imputes the distemper or disease in turnips, which the Norfolk farmers call the hanbery; so named from a like distemper in a horse's heel. It is a warty excrescence, formed probably by this insect, in the same manner as galls are formed upon the leaves of the oak. In some years it takes off whole crops, and the turnips never thrive after it has begun to grow in them.

A gentleman, remarkable, among many other good qualities, for several excellent improvements which he has made in agriculture, tried with success the following experiment, to preserve turnips from the fly, and the better to secure their growth. He sowed the seed in a nursery, where there was least danger of slugs or the fly, and where they might easily be watered in case of great drought, to make them grow the quicker. They remained in this nursery, till they were large enough to be transplanted. By this means he gained some weeks longer, to perfect his fallow, or give a thorough plowing to ground which had borne a crop that season. He transplanted his turnips into the field, and by planting them regularly at due distances, greatly lessened the expence of hoeing; their regularity making it very easy to destroy the weeds from time to time, as they appeared.

In the second part of the Memoirs of the Society of Berne for the year 1762, the reverend Mr. Bertrand, not satisfied with even a scrupulous discharge of the duties of his clerical function, has instructed his parishioners, his country, and mankind, in the important subject of agriculture. The improving of light soils by the culture of turnips, is one of his objects: upon which he very judiciously observes, that though it be right to plough stiff lands before the winter, in order to their being mellowed by the frost; yet as the finest and best parts of the soil will be in danger of being washed off, or carried down into the loose earth underneath, when this is done in a light ground, or in mould which has a sandy or gravelly bottom; it will be most adviseable here, to turn

the stubble down immediately after the corn has been taken off, and then to sow turnips; because their spreading leaves will shelter and secure the fine mould upon the surface, and keep the land in good heart, whilst the earth will be loosened and divided by their roots, so that it will be rather fitter for a spring crop, than if it had lain uncultivated.

The chief use of turnips is, to feed cattle in the winter and spring, when there is a want of grafs for their pasture. Cows, oxen, and hogs, are very fond of this food, which fattens them, and increases the milk of the former. Sheep too eat it readily, and thrive upon it, when they have been used to it early; but they do not relish it when it has not been offered them till they are grown old: however, if they are kept fasting two or three days, most of them take to it, and when they have once tasted it, they become very fond of, and feed kindly upon it. In some places, they feed their lambs with turnips till the middle of April, though they then begin to run up to seed. Farmers choose rather to do this, than to let them hurt their clover, sain-foin, lucerne, &c. Some par-boil them a little, at first, till their cattle, and particularly their sheep, are accustomed to them: but a lamb only three weeks old, will, after it has once eaten of this food, scoop out a raw turnip with great glee.

Turneps, if not clean eaten, and well cleared off the ground, may take root again, run to seed, and do great damage to the ensuing crop. Mr. Lisle instances it in a gentleman of Berkshire, who plowed up a turnip field in the spring, and sowed it with peas: but the little dwarf turnips that were left behind, uneaten, notwithstanding his plowing them up, took root again, run to seed in great quantities, and did much damage to his crop of peas.

The practice of turning a flock of sheep, at random, into a large field of turnips, is very bad: for they will then spoil more in a fortnight, than would keep them a whole winter. The best way, therefore, of feeding them with these roots, is, as Mr. Tull advises, and after him M. Duhamel, one or other of the three following methods, which are equally applicable to the drill, and to the common, husbandry.

The first is, to portion out the turnip ground, by inclosing with hurdles so much only as the sheep can clear in one day; and so to advance the folds farther into the field every morning, until all be spent. But it is to be observed, that the sheep never eat them clean this way, but take only the leaves and the heart of the turnip: so that great part of them remains in the earth. It is true that these fragments, if left there, rot, and become a manure: but when they are wanted for the food of the flock, and are to that end pulled up with iron crooks or forks made for this purpose, the sheep do not relish, and consequently eat but little of, these then dirty withered remains, tainted with their urine, dung, &c. nor can they nourish them so well as roots which are fresh and cleanly.

The second method differs from the former only in pulling up the turnips so far as they are hurdled off, before the sheep are turned in. They then eat them better, because the food is fresh and in good condition. Besides, as the whole turnips are pulled up more easily than their pieces can be, there is not such waste as in the other way. The turneps which grow next to the hurdles should be thrown towards the middle of the space hurdled off; because they will be less liable to be trampled upon and spoiled there, than nearer to the hurdle, where the sheep run about most, in search of means of escaping into the open field.

The third way is to pull up the turnips, and carry them into some other ground, and there spread them every day on a new place, where the sheep will eat them up clean. This is done when there is land not far off, which has more need of dung than that where the turnips grow. The expence of carrying the turnips is compensated by saving the price, or at least the carriage and removing of the hurdles: only when the turnips are laid on a spot of grafs, as is frequently done in wet weather, the benefit of the dung and urine of the sheep is lost.

This method is requisite when the field on which the

turnips grow is wet; because, 1. The sheep would trample upon, and bury, part of the turnips, which would be lost. 2. In treading that wet earth, they would poach it, and render it unfit for corn. 3. By this means, a field may be dunged, as we have just observed, which wants it more than that where the turnips grew. 4. This must necessarily be done, if wheat has been sown in the alleys between the rows of turneps, according to the principles of the new husbandry.

Turnips are always carried off the field, when they are intended to fatten the larger sorts of cattle: and they should be cut in pieces for them, lest they choke themselves with the whole ones. They are given morning and evening to stall-fed cattle, which in the intervals, eat likewise common fodder; but the turnips increase their appetite to such a degree, that a middle sized bullock, stalled for fattening, will consume near 200 pounds weight of these roots in 24 hours, besides hay: whereas, if nothing but hay were given him, he would hardly eat half the quantity that he will with the turneps. A healthy bullock, in only good plight at the time of his beginning to be fed with turnips, will be very well fattened in three months.

Mr. Tull says he found by experience, that the best way of sowing turneps is in single rows, six feet asunder. He sowed them in double rows, also at that distance, but they did not do well: and he likewise sowed them in single rows, with intervals of only three feet. These last yielded a greater crop than a neighbouring field, which was sown and managed in the common way: but neither the single rows three feet asunder, nor the double rows with intermediate distances of six feet, yielded, says he, half so much, as the single rows six feet asunder: from whence he concludes, that it is best to leave a space of six feet between the rows; for that, if the alleys are well plowed, these turneps will thrive wonderfully, even though no other moisture falls but the dew, which will sink into the earth, to their roots.

However, notwithstanding Mr. Tull's experiment, M. Duhamel is for sowing turneps in double rows, if the intervals are of six feet; or if they are sown in single rows, he would have these rows be but four feet asunder, which is the space left between the rows of vines in Languedoc, and which is there plowed with oxen.

An ounce of seed will sow as much land when drilled, as a pound will in the common way: and if care be taken to distribute only the necessary quantity, a great deal of trouble will be saved in the hoeing of the plants afterwards, to thin them. But it is essential to observe, we must again repeat it, that all roots, whether turnips, carrots, parsneps, parsley, or any other, always thrive best where there is a great depth of fine, light, well loosened mould. M. Duhamel trenched the whole of his kitchen-garden three feet deep: all his pot-herbs grew very fine, and his roots in particular were of a surprising size.

Mr. Tull, by drilling his turnip seeds alternately at different depths in the earth, was sure to succeed in one part or other, whether the season was wet or dry. If wet, the seed slightly covered sprouted first; and in dry seasons, that which lay deepest was the first that rose. By this means, and by mixing the seed, half new and half old, for the new always comes up soonest, he had four comings up, which, as he observes, gave the plants so many chances to escape the fly.

If one was sure of having rain immediately after the turnips are sown, it would undoubtedly be right to sow them very shallow: but if no rain happens, they are best deeper in the earth, because they there meet with moisture sufficient to make them grow.

When the season has been so kindly that all the seeds have grown, and the plants have not suffered by the fly or other insects, they must be thinned early, that the ground may not be exhausted by such as are not intended to remain; for those that are left should be about a foot asunder.

When the turnips sown in drills thrive well, only each alternate alley need be hoed at one time, and the others a few days after; it being better to feed the plants gradually, by dividing the hoeings in this manner, than to give them a great deal of food at once, by hoeing all

the alleys together, and afterwards leave them double the time without any culture at all. Another advantage attending this method is, that the plants will be the less liable to be killed by hot dry weather, and the less apt to be damaged by heavy rains. But it will not, indeed, so effectually destroy weeds, which ought always to be a principal object of the husbandman's care, and which ever is one of the chief intentions of the new husbandry. However, as all weeds are very apparent in the alleys, it is easy to extirpate them there; and as to those which may chance to be in the rows, the person who thins the turnips may cut them up at the same time. He will there most easily distinguish the charlock from the turnips, especially when the leaves of these last are come to be about the breadth of a half crown.

All plants sown in single rows are greatly benefited by the alternate hoeing of the alleys between them: for, as M. Duhamel observes, 1. Four of these hoeings, which cost no more than two entire ones, are almost as beneficial to the plants as four complete hoeings. 2. A plant which finds a great deal of nourishment on one side, is the better able to thrive without receiving so much on the other. 3. If, in hoeing very near the plant, some of its roots are broke; those on the other side, not hoed, supply the wants of the plant, till the broken ones have made fresh shoots. 4. The horse-hoe may therefore be brought very near to the turnips, without fear of hurting them; provided it do not force them out of the earth. 5. When a farmer has a great quantity of turneps to hoe, they are sooner supplied by this culture, than they could possibly be if all the alleys were to be hoed.

A furrow should not be left open near the turnips, while they are young; because the earth about them would in that case become too dry: but there is no danger of this in the autumn, when they are grown strong, and the earth is moist. Neither is it advisable to leave a furrow open near them during the winter; because they would be in danger of being hurt by the frost.

When these plants are grown large, and their roots are consequently pretty well extended, the hoe-plough need not come quite so near them as at first: nor is it necessary to hoe them at all, till they are about the bigness of one's finger's end.

One alternate hoeing, or which is the same thing, two half hoeings, will be sufficient when the turnips are sown late. But when they are sown early, and many weeds grow, one hoeing will not be enough.

By following this culture, M. Duhamel has seen turnips which weighed from sixteen to nineteen pounds; and we may depend on their weighing one with another twelve pounds a-piece in a good soil, which is a vast produce from an acre of land. Mr. Miller says, that one acre of turnips, thus properly cultivated, will afford more feed for sheep or ewes in the winter, than fifty acres of the best pasture at that season.

Another vast advantage which attends the sowing of turnips in rows, is, that instead of occupying the whole ground when it should be sowed with wheat, and sometimes even when it should be sowed with spring-corn, as is frequently the case in the old way; they are no hindrance to either in the new husbandry: for as the alleys are in good tilth, three rows of corn may be sown, seven inches asunder, between the rows of turnips; and when these roots are pulled up, the ground where they grew is hoed, and becomes the alleys between the beds of corn.

The best turnip seeds are obtained from the largest roots, which may either be transplanted for that purpose, or marked out in the field where they were sown. Those which are commonly sold in the shops, seldom produce the finest plants.

We shall close this article with the following

Experiments on TURNIPS cultivated according to the new Husbandry. In 1754, M. de Chateauvieux sowed turnips on beds, in two rows. They suffered greatly for want of rain, and none of them grew to the size they would have done in a more favourable season. Some of them weighed eight pounds; but their general weight was from three to four.

In 1755, M. de Chateauvieux sowed some beds with one row, some with two, and others with three rows. They

They were afterwards thinned, so that the plants stood a foot asunder in the rows. Those sown in one row were the largest, and in general, the most equal. Some of them weighed fourteen pounds, and most of them from seven to eight. In the other rows, they did not weigh so much; but they were more numerous.

In consequence of these experiments, M. Duhamel, to whom they were communicated, makes the following striking calculation relative to the quantity of food which turnips will afford for cattle.

"Let a square whose side is 216 feet be formed into beds four feet wide, which is sufficient for one row of turnips. These will be 216 feet long, and consequently will contain that number of turnips, planted a foot asunder. These 216 multiplied by 54, the number of beds, will give 11664 turnips for the product of the square; and these multiplied by six, the supposed weight of each turnip, will give 69,984 pounds for the weight of all the turnips on this spot."

This may be looked upon as a very considerable crop; for it will be sufficient to stall-feed four bullocks during the three winter months, at the daily allowance of 200 pounds each: and yet there is reason to believe that the quantity will be doubled in a good year, as will be pretty evident to those who consider at how low a rate the medium weight of the turnips is here estimated.

In 1755, M. Duhamel sowed turnips in a field, on beds cultivated with the horse-hoe. They grew extremely fine; many of them being twenty-nine inches circumference.

TURNPIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travellers, waggons, coaches, &c. to take toll of them towards repairing or keeping the roads in repair.

Justices of the peace, and other commissioners, are authorized to appoint surveyors of the roads, and collectors of toll, which is usually 1s. or 6d. for a coach or waggon, and 1d. for a horse, &c.

In case any persons shall drive horses or other cattle, through grounds adjoining to the highways, thereby to avoid the toll, they are liable to forfeit 10s. Likewise if any one assaults a collector of the tolls, or by force passes through a turnpike-gate without paying, he forfeits 5l. leviable by justices of peace; and maliciously pulling down a turnpike is deemed felony, &c. It is also enacted, that 20s. shall be paid for every hundred that a carriage with its loading weighs above 6000 pound weight, and that engines may be set up at turnpikes for weighing such carriages.

TURNPIKE, is also used in the military art for a beam stuck full of spikes, to be placed in a gap, a breach, or at the entrance of a camp, to keep off an enemy. See *CHEVAUX de Frise*.

TURNSOLE, or **TORNSOLE**, *Heliotropium*, in botany, a genus of plants whose flower is monopetalous and saucer-shaped; the tube is the length of the cup; the limb is plane, divided lightly into five segments, and obtuse: the smaller segments stand alternate and are acute; the larger are placed between: the mouth is closed by five prominent squamulae, joined in the form of a star; there is no pericarpium, the calyx remains unaltered, and contains four oval acuminate seeds.

A decoction of common turnsole purges phlegm and bile. It is good against the sting of serpents: the leaves are said to take away warts, ulcers, gangrenes, and scrophulous tumours.

It is said that the berry of the heliotropium, which grows wild about Montpellier, stains paper of a green colour, and that this green turns presently to a blue: that the common blue paper receives its colour from this juice: and that the red rags called turnsole, employed for colouring wines and other liquors, are tinged by the same juice turned red by acids. According to M. Nissolle of the French Academy of Sciences, the colouring juice is obtained, not from the berries, but from the tops of the plant, gathered in August, ground in mills, and then committed to the press. The juice is exposed to the sun, moistened by the vapour which arises during the slaking of quick-lime with urine, then dried again in the sun, and dipt again in the juice. The

Dutch and others are said to prepare turnsole rags, and turnsole in the mass, from different ingredients, among which archil is a principal one.

TURPENTINE, *Terebenthina*, in the materia medica, a native balsam, or resinous juice of certain trees, flowing either naturally or by incision. Four kinds of turpentine are distinguished in the shops.

1. Chio, or Cyprus, turpentine, generally about the consistence of thick honey, very tenacious, clear and almost transparent, of a white colour, with a cast of yellow and frequently of blue, of a warm pungent bitterish taste, and a fragrant smell more agreeable than that of any of the other turpentines. It is the produce of the common terebinth, an evergreen bacciferous tree or shrub, growing spontaneously in the eastern countries and in some of the southern parts of Europe.

The turpentine brought to us is extracted in the islands whose name it bears, by wounding the trunk and branches a little after the buds have come forth: the juice issues thin and clear as water, and by degrees thickens into the consistence in which we meet with it. A like juice, exuding from this tree in the East, inspissated by a slow fire, is said by Kæmpfer to be used as a masticatory by the Turkish women, for preserving the teeth, sweetening the breath, and promoting appetite.

2. Venice turpentine, usually thinner than any of the other sorts, of a clear whitish or pale yellowish colour, a hot pungent bitterish disagreeable taste, and a strong smell, without any thing of the fine aromatic flavour of the Chian kind. The true Venice turpentine is said to be obtained from the larch, a coniferous tree, with small cones, and short leaves standing in tufts, which fall off in the winter, growing in great abundance on the Alps and Pyreneans, and not uncommon in the English gardens. Though this kind of turpentine bears the name of Venice, it is not the produce of the Venetian territories: the greatest quantities are brought from New England.

3. Strasburg turpentine, generally of a middle consistence between the two foregoing, more transparent and less tenacious than either, in colour yellowish brown, in smell more agreeable than any of the other turpentines except the Chian, in taste the bitterest yet least acrid. This juice is extracted, in different parts of Germany, from the silver and red fir, by cutting out, successively, narrow strips of the bark, from as high as a man can reach to within two feet of the ground. In some places, a resinous juice is collected from certain knots under the bark: this is accounted superior to the turpentine.

4. Common turpentine, about the consistence of honey, of an opaque brownish white colour, the coarsest, heaviest, in smell and taste the most disagreeable of all the kinds of turpentine. It is obtained from the wild pine, a low coniferous tree, with the leaves longer than those of the firs, and issuing two together from one tubercle, growing wild in different parts of Europe. This tree is extremely resinous, insomuch that, if not evacuated by its juices, it often swells and bursts. The juice, as it issues from the tree, is received in trenches made in the earth, and afterwards freed from its grosser impurities by colature thro' wicker baskets. The cones of the tree appear to contain a resinous matter of a more grateful kind than that of the trunk: distilled while fresh, they are said to yield a fine essential oil greatly superior to that of the turpentines.

All these juices dissolve totally in rectified spirit, but give out little to watery menstrua: they become miscible with water, into a milky liquor, by the mediation of the yolk or white of an egg, and more elegantly by mucilages. Distilled with water, they yield a notable quantity of a subtle penetrating essential oil vulgarly called spirit; a yellow or blackish resin remaining in the still: this is the common rosin of the shops. It is supposed that the officinal Burgundy pitch, which is brought from Saxony, is a preparation of the same kind, only less divested of the oil, made by boiling the common turpentine till it acquires a due consistence. The essential oil, redistilled by itself in a retort, with a very gentle heat, becomes more subtle, and in this state is called ethereal, a thick matter remaining behind, called balsam

balsam of turpentine. A like balsam is obtained also by distilling, with a stronger fire, the common resin; from which there arises, first a thin yellow oil, and afterwards the thicker dark-reddish balsam, a blackish resin remaining in the retort.

All the turpentine are hot stimulating corroborants and detergents. They are given, where inflammatory symptoms do not forbid their use, from half a scruple to half a dram and upwards, for cleansing the urinary passages and internal ulcerations in general, and in laxities of the feminal and uterine vessels. They seem to act in a peculiar manner on the urinary organs, impregnating the water with a violet smell, even when applied externally, particularly the Venice sort. This last is accounted the most powerful as a diuretic and detergent, and the Chio and Strasburgh as corroborants: they all loosen the belly, the Venice most; and on this account they are supposed by Riverius and others to be less hurtful than such irritating diuretics, as are not accompanied with that advantage. The common turpentine, as being the most offensive, is rarely given internally: its principal use is in some external applications, among the farriers, and for the distillation of the oil.

The oil is a most potent stimulating detergent diuretic. It is sometimes given, in doses of a few drops, in rheumatisms and fixed pains of the joints; and some have ventured on much larger quantities. Cheyne recommends, as a perfect cure for sciaticas, though of many years standing, from one to four drams of the ethereal oil, to be taken with thrice its quantity of honey, in a morning fasting, with large draughts of sack-whey after it, and an opiate at bed-time: this medicine is to be repeated, with the intermission of a day now and then, if daily repetitions cannot be borne, for four or five days, or eight at furthest. It appears, however, highly imprudent, to venture on such large doses at once of a medicine so very hot and stimulating. Boerhaave after recounting, not without some exaggeration, its styptic, anodyne, healing, antiseptic, and discutient virtues when applied hot externally, and its aperient, warming, sudorific and diuretic qualities when taken internally, adds, that it must be used with great caution; that when taken too freely, it affects the head, excites heat and pain therein, and, violently urging a diabetes, brings on a flux of the semen and of the liquor of the prostates; and that in venereal runnings, in which it has by some been commended, it tends to inflame the parts and increase the disorder.

The balsam and the inspissated resins are used chiefly externally: the balsam is less pungent than the oil, and the resins much less so than the turpentine in substance. The common yellow resin, in taste considerably bitter, is sometimes given as an internal corroborant, in preference to the turpentine themselves, as being divested of the stimulating oil.

TURRITIS, tower mustard, in botany, a genus of plants; the empalement of the flower is composed of four oblong oval leaves, which close together. The flower has four oblong, oval, entire petals, placed in form of a cross, and six erect awl-shaped stamina the length of the tube, two of which are shorter than the other, terminated by single summits, and a taper germen a little compressed, having no style, but is crowned by an obtuse stigma. The germen afterwards becomes a long four cornered pod with two cells, which are divided by an intermediate partition, opening with two valves, and filled with small, roundish, indented seed.

Mr. Miller has enumerated three species of this plant: the first sort grows naturally in several parts of England upon walls and dry banks; this hath its lower leaves much jagged on their edges, and rough. The stalks rise two feet high, garnished with smooth greyish leaves, ending in points, which embrace the stalks with their base. The upper part of the stalk has slender branches, proceeding from the wings of the leaves, which sustain spikes of small white flowers, having four petals, placed in form of a cross. These are succeeded by long, slender, compressed, four cornered pods, which grow erect close to the stalk, filled with small seeds.

The second sort grows naturally upon old walls and buildings in the northern counties of England; the

lower leaves are shaped like those of the daisy, but rough. The stalks rise eight or ten inches high, garnished with oval leaves, whose bases embrace the stalks; they are as rough as the lower leaves. The upper part of the stalks branch into slender stalks, which sustain short spikes of white flowers, like those of the former sort, which are succeeded by slender pods, having four corners shorter than those of the first sort.

The third sort grows naturally in rough stony ground about Montpellier. This is much smaller than either of the former; the leaves are smooth, and all of them entire; the stalks are erect, and seldom branch; the leaves embrace them with their base. The flowers and pods are like the former, but are smaller.

These plants are kept in botanic gardens for variety; but if their seeds are scattered upon an old wall or building in autumn, soon after they are ripe, the plants will come up, and thrive without farther care, and their seeds will scatter on the walls and spread, so there will be no danger of the plants maintaining their situation, if they are not purposely destroyed.

TURUNDA, in medicine and surgery, denotes a tent, pallet, or pencil; or a piece of lint thrust into a wound, ulcer, &c.

TURTLE, in ichthyology, a name given to some species of the testudo, as the hawk's bill turtle is the testudo with acuminate unguis, four on the hinder as well as the fore feet; the green turtle, or the testudo with two unguis on the fore feet, and one on the hinder; and the long headed turtle, or the great oval headed testudo. See **TESTUDO**.

TURTLE-DOVE, in zoology, a very beautiful little bird of the pigeon kind. The head, neck, and back, are of the bluish grey colour of the common pigeon, with some mixture of a reddish brown near the rump, and at the bottom of the neck. Its breast and belly are white; but its throat of a fine bright purple; and the sides of the neck are variegated with a sort of ringlet of beautiful white feathers, with black bases.—It feeds on hempseed, and other vegetable matters.

TURTLE-SHELL, in natural history, the name given by the collectors of shells to a very beautiful species of murex, common in the cabinets, but not found any where on the shores. This is owing to its having greatly altered its appearance in the polishing; for it is no other than the white and brown mouthed murex, which is common in its rough state, with its outer coat taken off.

TUSCAN ORDER, in architecture, the first, simplest, and most massive of the five orders. See plate XLIII. *fig. 1.*

The Tuscan order takes its name from an ancient people of Lydia, who coming out of Asia to people Tuscany, first executed it in some temples, which they built in their new plantations.

The Tuscan is called the Rustic order by Vitruvius, and M. de Cambray agrees with him, who in his *Parallel*, says, it never ought to be used but in country-houses and palaces. M. Le Clerc adds, that in the manner Vitruvius, Palladio, and some others, have ordered it, it does not deserve to be used at all. But in Vignola's manner of composition, he allows it beauty, even in its simplicity, and such as makes it proper, not only for private houses, but even for public buildings, as in the piazzas of squares and markets, in the magazines and granaries of cities, and even in the offices and lower apartments of palaces.

The Tuscan has its character and proportions as well as the other orders; but we have no antient monuments to give us any regular Tuscan pillar for a standard. M. Perrault observes, that the characters of the Tuscan are nearly the same with those of the Doric, and adds, that the Tuscan is in effect no more than the Doric made somewhat stronger, by shortening the shaft of the column; and simpler, by the small number, and largeness of the mouldings. See **DORIC**.

Vitruvius makes the whole height of the order fourteen modules, in which he is followed by Vignola, M. Le Clerc, &c. Serlio makes it but twelve. Palladio gives us but one Tuscan profile, much the same as that of Vitruvius, and another too rich, on which side Scamozzi

mozzi is likewise too faulty. Hence, it is, that that of Vignola, who has made the order very regular, is most followed by the modern architects.

Of all the orders, the Tuscan is the most easily executed, as having neither triglyphs nor dentils, nor modillions to cramp its intercolumns. On this account, the columns of this order may be ranged in any of the five manners of Vitruvius, viz. the pycnostyle, systyle, eustyle, diastyle, and aræostyle.

TUSCAN Order by Proportions of equal Parts. The height of the pedestal, being two diameters, is divided into 4, giving 1 to the base, whose plinth is $\frac{2}{3}$ thereof; the other part is divided into three, giving one to the fillet, and two to the hollow. The breadth of the die or naked is one diameter and $\frac{1}{2}$, and the projection of the base is equal to its height, the fillet hath three-fourths thereof. The height of the cornice is half the base, being $\frac{1}{2}$ of the whole height, and is divided into 8, giving 2 to the hollow, 1 to the fillet, and 5 to the band; the projection is equal to the base, and the fillet hath three of these parts. Base of the column: the height is one half a diameter; and is divided into six parts, giving three to the plinth, 2 and $\frac{1}{2}$ to the torus, and $\frac{1}{2}$ a part to the fillet; the whole projection is $\frac{1}{4}$ of its height. The hollow, or cincture, is one fourth of a circle, in all the orders, and belongs to the shaft of the column.

The diminishing of this column is $\frac{1}{4}$ of the diameter, and is divided into 9, giving 2 $\frac{1}{2}$ to the frieze of the capital, $\frac{1}{2}$ a part to the fillet, 3 to the ovolo, and 3 to the abacus. The whole projection is $\frac{1}{8}$ of the diameter, being perpendicular to the body of the column below, and the fillet projects equal to its height. The collerino, or necking of all the orders in general, is one of those nine parts in the capital, and the fillet half a part, the projection is 1 and $\frac{1}{4}$ of these parts, and the fillet equal to its height. The height of the entablature being one diameter and $\frac{1}{4}$, is divided into 6, giving 2 to the architrave, 1 $\frac{1}{2}$ to the frieze, and 2 $\frac{1}{2}$ to the cornice.

For the members of the architrave, divide the height into seven parts, giving 2 $\frac{1}{2}$ to the first face, 3 $\frac{1}{2}$ to the second, and 1 to the band at top. The projection is equal to the band, and the second face a third thereof. The first face of all the architraves is perpendicular to the naked of the column at the top. For the cornice, divide the height into 9, giving 1 $\frac{1}{2}$ to the hollow, $\frac{1}{2}$ to the fillet, 1 $\frac{1}{2}$ to the ovolo, 2 to the corona, $\frac{1}{2}$ a part to the fillet, 2 to the scima recta, and 1 to the fillet. For the projections, the hollow hath 2 of these parts, the ovolo 3 $\frac{1}{2}$, the corona 6, the fillet 6 $\frac{1}{2}$, and the whole 9 being equal to the height. See the figure.

TUSCAN EARTH, a yellowish, white, pure bole, considerably heavy, of a very smooth surface, not easily breaking between the fingers, but adhering slightly to the tongue, and melting very readily in the mouth. It is dug in many parts of Italy, particularly about Florence, where there is a stratum of it eight or ten feet thick, at the depth of five or six from the surface. It is given as a sudorific, and esteemed a great medicine in fevers, attended with diarrhoeas. See the article **BOLES**.

TUSCULAN, in matters of literature, a term which frequently occurs in the phrase *Tusculan questions*. Cicero's Tusculan Questions are disputations on several topics in moral philosophy, which that great author took occasion to denominate from Tusculanum, the name of a country-seat or villa, where they were composed, and where he lays the scene of the dispute. They are comprised in five books; the first on the contempt of death, the second of enduring pain; the third on assuaging grief; the fourth on the other perturbations of the mind; and the last, to shew that virtue is sufficient to a happy life.

TUSSILAGO, colt's-foot, in botany, a genus of plants, the flower of which has one common cylindrical empalement, whose scales are linear, spear-shaped, and equal. The flower is made up of hermaphrodite florets, which compose the disk, and female half-florets, which form the rays or border. The hermaphrodite florets are funnel-shaped, cut at the brim into five segments; these

have five short hair-like stamina, terminated by cylindrical summits, and a short crowned germen, supporting a slender style, crowned by a thick stigma. The germen afterwards becomes an oblong compressed seed, crowned with a hairy down. The female half florets are stretched out on one side with a narrow tongue-shaped segment; these have no stamina, but have a short crowned germen, which turns to a seed like those of the hermaphrodite florets, which ripen in the empalement.

There are three species of colt's-foot, the first of which is very common in watery places in almost every part of England, and is rarely kept in gardens; for the roots creep under ground, and increase so fast, that in a short time they will spread over a large spot of ground.

The second sort grows naturally in Siberia; this is a very low plant, whose leaves grow close to the ground, of an oval form, indented on the sides like a lute. The flowers stand upon short foot-stalks, which rise between the leaves, each sustaining one flower at the top, of a dirty purplish colour. These are succeeded by downy seeds.

The third sort grows naturally on the Alps; this is a low perennial plant, whose leaves are round, indented at the foot-stalk in form of a heart; their edges are crenated; their upper surface is smooth, of a bright green colour; their under sides are a little downy and whitish. The foot-stalks of the flowers, which arise from the root, sustain one purplish flower at the top, which is made up of hermaphrodite and female florets, like those of the other sorts.

The two last are frequently kept in gardens for the sake of variety; they are easily propagated by parting their roots in autumn, and must be planted in a moist shady border, where they will thrive, and require no farther care but to keep them clean from weeds.

The leaves and flowers of colt's-foot, in taste somewhat mucilaginous, bitterish, and roughish, and of no remarkable smell, are ranked among the principal pectoral herbs. Infusions of them, with a little liquorice, or with the other herbs of similar intention, are drank as tea, and sometimes with considerable benefit, in catarrhus disorders and coughs threatening consumptions.

TUTELARY, *Tutelaris*, one who has taken something into his patronage and protection.

It is an ancient opinion, that there are tutelary angels of kingdoms and cities, and even of particular persons, called Guardian angels.

The ancient Romans, it is certain, had their tutelary gods, whom they called *Penates*. — And the Romish church to this day, hold an opinion not much unlike it: they believe that every person, at least every one of the faithful, has, from the time of his birth, one of those tutelary angels attached to his person, to defend him from all temptations; and it is on this, principally, that their practice of invoking angels is founded.

F. Anthony Macedo, a Portuguese Jesuit of Coimbra, has published a large work in folio, on the tutelary saints of all the kingdoms, provinces, and great cities of the Christian world, *divi tutelares orbis christiani*, at Lisbon, 1678.

TUTOR, in the civil law, is one chosen to look to the person and estate of children left by their fathers and mothers in their minority. A person nominated tutor either by testament, or by the relations of the minor, is to decline that office if he have five children alive, if he have any other considerable tutorage, if he be under twenty-five years of age, if he be a priest, or a regent in an university, or if he have any law-suit with the minors, &c. The marriage of a pupil, without the consent of his tutor, is invalid. Tutors may do any thing for their pupils, but nothing against them; and the same laws which put them under a necessity of preserving the interest of the minors, put them under an incapacity of hurting them.

TUTOR, is also used in our universities for a member of some college or hall, who takes on him the instruction of some young students in the arts or faculties.

TUTORAGE, *Tutela*, in the civil law, a term equivalent to guardianship in the common law, signifying

an office imposed on any one to take care of the effects of one or more minors.

By the Roman law, there are three kinds of tutorage; testamentary, which is appointed by the father's testament; legal, which is given by the law to the nearest relation; and dative, which is appointed by the magistrate. But in all customary provinces, as France, &c. all tutorage is dative and elective, and though the father have by testament nominated the next relation to his pupil, yet is not that nomination of any force, unless the choice be confirmed by that of the magistrate, &c. By the Roman law, tutorage expires at fourteen years of age.

TUTTY, *Tutia*, an argillaceous ore of zinc, found in Persia; formed on cylindrical moulds into tubulous pieces like the bark of a tree, and baked to a moderate hardness; generally of a brownish colour, and full of small protuberances on the outside, smooth and yellowish within, sometimes whitish, and sometimes with a bluish cast. Like other argillaceous bodies, it becomes harder in a stronger fire; and after the zinc has been revived and dissipated by inflammable additions, or extracted by acids, the remaining earthy matter affords, with oil of vitriol, an aluminous salt.

Tutty, levigated into an impalpable powder, is, like the lapis calaminaris and calces of zinc, an useful ophthalmic, and frequently used as such in ointments and collyria. Ointments for this intention are prepared in the shops, by mixing the levigated tutty with so much vipers fat as is sufficient to deduce it to a due consistence, or by sprinkling half an ounce of the powder into two ounces of fresh butter and a dram of white wax liquefied together, to which is occasionally added a dram or two of camphor.

TWELFTH-DAY, or **TWELFTH-TIDE**, the festival of the Epiphany, or the manifestation of Christ to the Gentiles; so called, as being the twelfth day, exclusive, from the Nativity or Christmas-day.

TWELVE MEN, otherwise called jury, or inquest, is a number of twelve persons, or upwards as far as twenty-four; by whose oath, as to matters of fact, all trials pass, both in civil and criminal cases, through all courts of the common law in this realm. See **JURY** and **TRIAL**.

TWILIGHT, *Crepusculum*, that light, whether in the morning before sun-rise, or in the evening after sun-set, supposed to begin and end when the least stars that can be seen by the naked eye cease, or begin, to appear, represented in plate CXXXIV. fig. 2. by that obscure part comprehended between HO AB, which is neither dark nor light. This is the twilight, the line AB being 18° below the horizon HO; and during the time the sun passeth from HO to AB, in the parallel of any day, his rays are partly refracted by the atmosphere, and so we have some faint light till he gets below the limit AB, when we are left in total darkness. Or it is twilight, while the sun is passing from X to R, from Y to S, and from Z to M, on the days the sun describes the parallels TR, AE Q, and V W. By means of the atmosphere it happens, that though none of the sun's direct rays can come to us after it is set, yet we still enjoy its reflected light for some time, and night approaches by degrees. For after the sun is hid from our eyes, the upper part of our atmosphere remains for some time exposed to its rays, and from thence the whole is illuminated by reflection. But as the sun grows lower and lower, that portion of the atmosphere which is above our horizon, becomes enlightened till the sun has got eighteen degrees below it; after which it ceases to be illuminated thereby, till it has got within as many degrees of the eastern side of the horizon; at which time it begins to illuminate the atmosphere again, and in appearance to diffuse its light throughout the heavens, which continues to increase till the sun be up.

Hence it is, that during that part of the year in which the sun is never eighteen degrees below our horizon, there is a continued twilight from sun-setting to sun-rising. Now that part of the year in the latitude of London, is while the sun is passing from about the fifth degree of Gemini to the twelfth of Cancer; that is, from about the 26th of May to the 18th of July: for

when the sun describes the parallel TR, that is, the tropic of Cancer, there is no dark night at all; for the parallel of that day, TR, doth not touch AB, nor will it for about a month before and after. On the other hand, the shortest twilight in the year happens about the 14th of October and 4th of March, for then the sun describes the parallel whose distance *eo* is the least between HO and AB of any other whatsoever.

As the twilight depends on the quantity of matter in the atmosphere fit to reflect the sun's rays, and also on the height of it, for the higher the atmosphere is, the longer will it be, before the upper parts of it will cease to be illuminated, the duration of it will be various. For instance, in winter, when the air is condensed with cold, and the atmosphere upon that account lower, the twilight will be shorter; and in summer, when the limits of the atmosphere are extended by the rarefaction and dilatation of the air, of which it consists, the duration of the twilight will be greater. And for the like reason, the morning twilight, the air being at that time condensed and contracted by the cold of the preceding night, will be shorter than the evening one, when the air is more dilated and expanded.

TWINS, two young ones delivered at a birth, by an animal which ordinarily brings forth but one.

TWINS, in astronomy, the same with Gemini. See the article **GEMINI**.

TWIST of a rope, cord, &c. See **ROPE**, &c.

TWIST is also used for the inside or flat part of a man's thigh, upon which a true horseman rests when on horseback.

To **TWIST** an horse, is violently to wring or twist his testicles twice about, which causes them to dry up, and deprives them of nourishment, and reduces the horse to the same state of impotency with a gelding.

TYCHONIC SYSTEM, or **HYPOTHESIS**, an order or arrangement of the heavenly bodies, of an intermediate nature between the Copernican and Ptolemaic, or participating alike of them both.

This system had its name and original from Tycho Brahe, a nobleman of Denmark, who lived in the latter part of the last century. This philosopher, though he approved of the Copernican system, yet could not reconcile himself to the motion of the earth; and being on the other hand convinced the Ptolemaic scheme could not be true, he contrived one different from either, as represented plate CXXV. fig. 2. In this the earth has no motion allowed it, but the annual and diurnal phenomena are solved by the motion of the sun about the earth, as in the Ptolemaic scheme; and those of Mercury and Venus are solved by this contrivance, though not in the same manner, nor so simply and naturally as in the Copernican system. The Tychonic system then supposed the earth in the center of the world, that is, of the firmament of stars, and also of the orbits of the sun and moon; but at the same time it made the sun the center of the planetary motions, viz. of the orbits of Mercury, Venus, Mars, Jupiter, and Saturn. Thus the sun, with all its planets, was made to revolve about the earth once a year, to solve the phenomena arising from the annual motion, and every twenty-four hours, to account for those of the diurnal motion. But this hypothesis is so monstrously absurd, and contrary to the great simplicity of nature, and, in some respects, even contradictory to appearances, that it obtained but little credit, and soon gave way to the Copernican system.

After this scheme had been proposed for some time, it received a correction by allowing the earth a motion about its axis to account for the diurnal phenomena of the heavens; and so this came to be called the Semi-tychonic system. But this was still void of the truth, and encumbered with such hypothesis, as the true mathematician and the genuine philosopher could never relish.

TYGER, or **TIGER**, in zoology. See the article **TIGER**.

TYLE, or **TILE**, in building, a sort of thin, fictitious, laminated brick, used on the roofs of houses; or more properly a kind of fat clayey earth, kneaded and moulded, of a just thickness, dried and burnt in a kiln like a brick, and used in the covering and paving of houses. See **BRICK**.

TYL

Tyles are made, says Mr. Leybourn, of better earth than brick-earth, and something nearer akin to the potter's earth. According to 17 Edward IV. the earth for tyles should be cast up before the first of November, stirred and turned before the first of February, and not made into tyles before the first of March; and should likewise be tried and severed from stones, marle, and chalk. For the method of burning them, see the article BRICK.

As to the method of applying tyles, some lay them dry as they come from the kiln, without mortar or any thing else; others lay them in a kind of mortar made of loam and horfedung. In some parts, as in Kent, they lay them in moss.

There are various kinds of tyles, for the various occasions of building; as plain, thack, ridge, roof, crease, gutter, pan, crooked, Flemish, corner, hip, dormar, scallop, astragal, traverse, paving, and Dutch tyles.

Plain or thack tyles, are those in ordinary use for covering of houses. They are squeezed flat, while yet soft, in a mould. They are of an oblong figure, and by 17 Ed. IV. c. 4. are to be $10\frac{1}{2}$ inches long, and $6\frac{1}{4}$ broad, and half an inch and half a quarter thick. But these dimensions are not over strictly kept to. Ridge, roof, or crease tyles, are those used to cover the ridges of houses, being made circular breadth-wise, like an half cylinder: they are, by the aforesaid statute, to be 13 inches long, and of the same thickness with the plain tyles. Hip or corner tyles, are those which lie on the hips or corners of roofs. As to form, they are first made flat like plain tyles, but of a quadrangular figure, whose two sides are right lines and two ends arches of circles, one end being a little concave and the other convex. The convex end is to be about seven times as broad as the concave end, so that they would be triangular but that one corner is taken off; then, before they are burnt, they are bent on a mould breadth-wise, like ridge tyles. They have an hole at their narrow end to nail them on by, and are laid with their narrow end upwards; by statute they are to be $10\frac{1}{2}$ inches long, and of a convenient breadth and thickness. Gutter-tyles, are those which lie in gutters or valleys in cross buildings. They are made like corner tyles, only the corners of the broad end are turned back again with two wings. They have no holes in them, but are laid with the broad end upwards, without any nailing. They are made in the same mould as the corner tyles, and have the same dimensions on the convex side. Their wings are each four inches broad, and eight long. Pan, crooked, or Flemish tyles, are used in covering of sheds, lean to's, and all kinds of flat roof buildings. They are in form of an oblong parallelogram, as plain tyles, but are bent breadth-wise forwards and backwards in form of an S, only one of the arches is at least three times as big as the other; which biggest arch is always laid uppermost, and the less arch of another tyle lies over the edge of the great arch of the former. They have no holes for pins, but hang on the laths by a knot of their own earth. They are usually $14\frac{1}{2}$ inches long, and $10\frac{1}{2}$ broad. By 12 Geo. I. c. 25. they are to be, when burnt, not less than $13\frac{1}{2}$ inches long, and $9\frac{1}{2}$ inches wide, and half an inch thick. Dormar or tympan tyles consist of a plain tyle and a triangular piece of a plain one standing up at right angles to one side of the plain tyle, and swept with an arch of a circle from the other end, which end terminates in a point. Of these tyles there are two kinds, the triangular piece in some standing on the right, in others on the left side of the plain tyle. And of these again there are two kinds, some having a plain whole tyle, others but half a plain tyle. But in them all the plain tyle has two holes for the pins at that end where the broad end of the triangular piece stands. Their use is to be laid in the gutters betwixt the roof and the cheeks or sides of the dormars, the plain part lying on the roof, and the triangular part standing perpendicularly by the cheek of the dormar; they are excellent to keep out the wet in those places, and yet they are hardly known any where but in

TYM

Suffex. The dimensions of the plain tyle part, are the same as those of a plain tile, and the triangular part is of the same length, and its breadth at one end seven inches, and at the other nothing. Scallop or astragal tyles are in all respects like plain tyles, only their lower ends are in form of an astragal, viz. a semi-circle with a square on each side. They are used in some places for weather tyling. Transverse tyles, are a kind of irregular plain tyles, having the pin holes broken out, or one of the lower corners broken off. These are laid with the broken end upwards, upon rafters where pinned tyles cannot hang. Flemish or Dutch tyles are of two kinds, ancient and modern. The antient were used for chimney foot-paces; they were painted with antique figures, and frequently with postures of soldiers, some with compartments, and sometimes with moresque devices; but they come much short of the design and colours of the modern ones. The modern Flemish tyles are commonly used plastered up in the jaumbs of chimneys instead of chimney-corner stones. These are better glazed, and such as are painted, for some are only white, are done with more curious figures and more lively colours than the ancient ones. But both kinds seem to be made of the same whitish clay as our white glazed earthen ware; the modern ones are commonly painted with birds, flowers, &c. The ancient ones are only five inches and a quarter square, and about three quarters of an inch thick; the modern ones six inches and a half square, and three quarters of an inch thick.

TYLE, in assaying, a small flat piece of dried earth used to cover the vessels in which metals are in fusion. Cramer directs, that these be made of a mixture of clay and sand, or powder of flints, or broken crucibles, formed into a paste, and spread thin with a rolling pin on a table, or flat stone. From these cakes or plates, pieces are to be cut with a knife, to the shape and size of the mouth of the vessels to be closed. It is best then to pare away the borders of the under surface of the piece thus cut off, that this surface may immediately touch all the way the edge of the mouth of the vessel, leaving a prominent rim, by which means the tyle fits close upon the vessel, and is not so easily displaced by accidents, as a touch of the poker, or of the coals put on to mend the fire, as it otherwise would be. Finally, put on the middle of the outer surface a small bit of the same matter, which serves as a kind of handle, by means of which it may be conveniently managed by the tongs, and easily taken off and put on again at pleasure.

TYLER, one that covers, or paves with tyles.

TYLWITH, in matters of heraldry and descent, is sometimes used for a tribe or family branching out of another, which the modern heralds more usually call the second or third house.

TYMPAN, or TYMPANUM, in architecture, the area of a pediment, being that part which is in a level with the naked of the frieze. Or it is the space included between the three corniches of a triangular pediment, or the two corniches of a circular one.

Sometimes the tympan is cut out, and that part filled with an iron lattice to give light, and sometimes it is enriched with sculpture in bass-relievo.

TYMPAN, among joiners, is also applied to the panels of the doors.

TYMPAN of an Arch, is a triangular space or table in the corners or sides of an arch, usually hollowed, and enriched sometimes with branches of laurel, olive-tree, or oak, or with trophies, &c. sometimes with flying figures, as Fame, &c. or sitting figures, as the cardinal virtues.

TYMPAN, among printers, a double frame belonging to the press, covered with parchment, on which the blank sheets are laid in order to be printed off. See the article PRINTING.

TYMPANUM, or TYMPAN, in mechanics, a kind of wheel placed round an axis or cylindrical beam; on the top of which are two levers or fixed staves, for the more easy turning the axis, in order to raise a weight required.

quired. The tympanum is much the same with the peritrochium, but that the cylinder of the axis of the peritrochium is much shorter, and less than the cylinder of the tympanum.

TYMPANUM of a Machine, is also used for an hollow wheel, wherein one or more people, or other animals, walk to turn it; such as that of some cranes, calendars, &c.

TYMPANUM, a drum. See **DRUM**.

TYMPANUM, in anatomy, the middle part of the ear. See **EAR**.

TYMPANY, *Tympanites*, in medicine, a flatulent tumour or swelling of the abdomen or belly, very hard, equable and permanent, whereby the skin is stretched so tight, that when struck it gives a sound like that of a drum. Hoffman observes that this disease has been generally accounted, both by the antients and moderns, a species of dropsy, but very improperly; for though it is often productive of, or complicated with an ascites, yet it is in itself a perfectly distinct disease, and accompanied with no extravasation of water in the abdomen; persons who have died of it having been found, on opening the body, with the abdomen as dry as in a state of health; but the stomach has been found, in some, greatly distended with flatulencies, and containing a viscid humour, though in no great quantity. The intestines are also usually found distended, and, as it were, pellucid, and, on being pricked, they collapse, without the appearance of any water. And, in some cases, on opening the abdomen, the whole swelling has subsided, on the exclusion of a gross flatulence which had distended it. The intestines have, in some subjects, been found distended to the bigness of a man's thigh, in some parts; and in others, lower down, so contorted and twisted together, that there could be no passage either for the wind or the excrements. It is not uncommon also, on dissection, to find great numbers of worms, of the common long kind, in the intestines.

A tympany, without a dropsy, is most incident to women after labour, when the lochia have been suppressed by colds or otherwise, or discharged in too small quantities; a bad regimen during the lying in, and the omitting to swathe the belly properly down, has also often a bad effect this way. In cases of this kind, women find soon afterwards the abdomen inflated, with a considerable uneasiness, a difficulty of breathing, costiveness, and an unaccountable anxiety. These are the breeding symptoms of the approaching tympany; and the same often happens after unskillful treatment in abortions, and after the leaving a part of the lochia behind, or the injuring the uterus in delivery.

Children are also subject to tympanies, when violently afflicted with worms, and sometimes after the measles and small-pox; and if due care is not taken of these cases, at their beginning, the superior parts soon become extenuated, and the patients die. Extreme voracity of children also, and their eating great quantities of food, at a time when the stomach is weak, sometimes brings on this disorder.

The tympany is justly accounted one of the more dangerous kinds of diseases, since the persons afflicted with it much oftener die than recover. When it is accompanied with a dropsy, it is scarce ever cured; and a simple tympany in women and children, if neglected at first, degenerates into a chronic disorder, and hardly admits of a cure. Some, indeed, have gone so far as to say, they never knew a patient, afflicted with a tympany, recover; but this seems too rash a judgment. That distension of the abdomen, which is properly called a flatulent colic, is by some accounted a species of tympany; but this is not naturally dangerous, and is easily cured, except when it is attended with spasms of the viscera; in which case the medicines given to restore the due tone of the intestines, are, by no means proper in regard to the spasms.

In curing flatulences of the stomach and intestines, the physician's principal intention is to promote a discharge of the vapours by the anus, and to attenuate and gently carry off, by stool, the tough and viscid matter, which contributes to the generation of the flatulences. For this

purpose, first derivative, discutient, and evacuating clysters are to be used, such as those prepared of hyssop, clary, flowers of common and roman chamomile, tops of yarrow, juniper-berries, and the larger carminative seeds, with veal broth, adding a sufficient quantity of sal gemmæ, sal ammoniac, or Epsom salt, and the oil of chamomile. But it is to be observed, that one or two clysters are not sufficient for removing the disorder, but they are to be frequently repeated. With these are to be interposed laxatives, possessed of a carminative, and, at the same time, somewhat of an anodyne quality. Or, if the patient is strong, and the inflation a real tympanites, two parts of the extractum panchymagogum Crollii, with one part of the pilulæ Wildegansii, or of the pilulæ Starckii, or pilulæ de styrace, in some very spirituous carminative water, is to be exhibited.

After these are to be used medicines possessed of a moderate balsamic principle, and a volatile, oleous, and aromatic salt, commonly called carminatives; but the operation of these medicines is not to be so explained, as if by their subtile volatile salt they attenuate the matter of the flatulences and rendered it thinner; but rather, because, by invigorating the tone and systole of the intestinal coats, they hinder the stagnation of the flatulences, move them from their seat, and render them more capable of being easily eliminated, or prevent the generation of new flatulences; for, as the destroyed peristaltic motion of the stomach and intestines is the principal cause of flatulences, so all the medicines which have a remarkable virtue in strengthening these parts, are most proper for the removal of this disorder. The best and most approved of this kind, are powders prepared of the roots of wake-robin, zedoary, and white burnet; the digestive salt of sylvius, or vitriolated tartar; cumin seeds, the tops of the lesser centaury, and dried orange peel, each a dram, and six drops of the genuine oil of chamomile; or of the oil of cedar, or of the oil of orange peel; to which if there is a suspicion of an acid lodged in the primæ viæ, we may commodiously add crabs eyes.

To this class of medicines may be referred the following liquid form: take of the carminative water of Dorncrellius, of the waters of common chamomile and zedoary prepared with wine, each one ounce; of the spiritus nitri dulcis, of the pure oil of carraway, eight drops mixed with two drams of sugar.

Nor are external remedies, such as linimenta applied by way of ointment to the whole epigastric region, to be neglected. The principal ingredients of these liniments ought to be boiled with oils of chamomile and rue, oil of nutmeg and Peruvian balsam, with which may be mixed the oils of juniper, carraway, anise, or cumins. But preferable to all others, the liquid balsam of life may be used, which when mixed with three parts of Hungary water, and applied by way of ointment to the abdomen, or laid on with a warm linen cloth, is found of great efficacy.

TYPE, *Typus*, a copy, image, or resemblance of some model.

The word is formed from the Greek, *τυπος*, form, figure.

The term type is less in use than its compounds prototype and archetype, which are the originals that are made without models.

TYPE, is also a scholastic term much used among divines, signifying a symbol, sign, or figure of something to come.

In this sense, the word is commonly used with relation to antitype, *αντιτυπος*, which is the thing itself, of which the other is a type or figure.

Thus, Abraham's sacrifice, the paschal lamb, &c. were types or figures of our redemption: and the brazen serpent was a type of the cross, &c.

Types are not mere conformities, or analogies, which the nature of things holds forth between them; nor arbitrary images arising merely from the casual resemblance of things; but there is further required a particular institution of God to make a type; and a particular declaration of his that it is so.

Gale divides types into historical and prophetic. The first are those used by the ancient prophets in their agitations and visions: the second those wherein things done, or ceremonies instituted in the Old Testament, prefigure Christ, or things relating to him in the New Testament.

The ancient fathers, as well as the modern critics, have been greatly divided about the nature and use of types, and typical representations, in the Old Testament; and it is this makes one of the great difficulties in understanding the ancient prophecies, and in reconciling the New and Old Testament together.

There is no denying but that there were some types which the Divine Wisdom instituted to be the shadows and figures of things to come: and yet people run into an excess that way; some looking for types in every thing; like Origen, who discovered mysteries in the very caldrons of the tabernacle. A prudent man should be contented with the more sensible and obvious ones; nor propose any without proving them as much as possible, and shewing that they were really intended for types, in order to justify the solidity of the reasoning of the apostles, who argued from them.

A late author maintains, that not the fathers only, but St. Paul himself, was of opinion, that, "Christianity was all contained in the Old Testament, and was implied in the Jewish history and law; both which are to be reputed types and shadows of Christianity." In order to which, he quotes Hebrews viii. 5. x. 1. and Colos. ii. 16, 17.—He adds, "That the ritual laws of Moses, being in their own nature no other than types and shadows of future good things, are to be considered as having the effect of prophecies."—This is likewise the sense of Mr. Whiston, and others; but the same author even quotes our Saviour speaking in behalf of this typical reasoning, in that passage Matth. xi. 13. where he affirms, that "The law prophecies; and that he came to fulfil the law as well as the gospel."

An ingenious divine takes this occasion to observe, that had the ancients, with the modern retainers to the typical way, expressly designed to have exposed Christianity, they could not have done it more effectually than by thus making every thing types and prophecies.—It is no wonder, he adds, that atheists and deists scoff at the credulity of Christians, and reject what is supported by such folly and absurdity.

Not that he denies the reality of such things as types. It is manifest, there were many under the Old Testament; such were Zachariah's slaves, beauty, and bands, ch. xi. 7, 10, 14. such was Hosea's adulterous wife ch. i. 2; and such were his children, ver. 4, 6.—The prophets designed by these to prefigure future events; but in these instances the reader is at once, by the declaration of the prophet, made to understand as much, and not left to his own conjectures about them, after the events are over.

In effect, all that is urged from scripture for the typical or allegorical interpretations of the Jewish law, history, ceremonies, &c. it is asserted, may be set aside without any violence to the sacred text, which may be explained on more natural and intelligible principles, and more consistently with grammar.

The word type we have observed, literally denotes no more than a copy or impression of any thing; and accordingly, in our translation, we find it sometimes rendered by print, sometimes by figure, sometimes by fashion, and sometimes by form.—Hence also the word is figuratively applied to denote a moral pattern; in which sense it signifies no more than example and similitude.

Again the word antitype, in scripture, signifies any thing formed according to a model or pattern; and thus in the Epistle to the Hebrews, the tabernacle, and holy of holies being made according to the pattern shewn to Moses, are said to be antitypes or figures of the true holy places.—In the like sense St. Peter speaking of the flood and the ark, whereby eight persons were saved, calls baptism an antitype thereto; by which he expresses no more than a similitude of circumstances. The other words used in scripture to imply a future event, prefigured by some foregoing act, are—*ὑποδείγμα*, rendered by imitation and example; and *σκια*, shadow.

This last word is frequently used by St. Paul, and applied to the Jewish law, ceremonies, priests, &c. which are represented as only shadows of things to come, or of heavenly things. It is from such general expressions, that people were led to mistake the apostle's design in these comparisons, and to assert, that all the Mosaic rites were types of, or designed to signify future events; and that the gospel is to be found in the pentateuch.—Whereas St. Paul's intent appears no other than to shew the great advantage of the gospel over the law in several particulars, wherein it has much preeminence as the substance has over the shadow.

If the shadow of things to come signify a prefiguration of future events, what are those events to which the Jewish new moons, Col. ii. 16. or the Jewish meats and drinks, have a respect? Or, how did the law of Moses, made of commands about persons, times, places, and sacrifices, prefigure a dispensation where regard to sacrifices, holy persons, times and places are so far from being enjoined, that they are declared useless. Can a particular holy place in the law be designed a prefiguration of a state where all places are equally holy?

Such being the import of all the terms used in the New Testament writers, seeming to imply any prefiguration of future events under the gospel, we may observe, 1. That to argue from types, is only to argue from examples or similitudes; and, consequently, that all inferences drawn from such reasonings, are no farther conclusive, than reasonings from similitudes are.—The intent of similitudes is only to help to convey some ideas more clearly or strongly; so that to deduce consequences from simile, or infer any thing from other parts of the simile than what are plainly similar, is absurd.

2. It cannot be proved that the ceremonies of the Mosaic law were even designed to prefigure any future events in the state of the Messiah's kingdom.—No such declared prefigurations are mentioned in the writings of the Old Testament, whatever notions prevailed among the writers who immediately followed. It is granted, that the apostles argued from the rites in the Mosaic institution; but this appears to have only been by way of illustration and analogy.

There is certainly a general likeness in all the dispensations of Providence; an analogy of things in the natural as well as the moral world, from which it is easy arguing by way of parity, and it is very just and usual so to do; but that one of these dispensations was therefore given to prefigure another that was future, can never be proved, unless it be expressly declared.—The Land of Promise, we know, was to be a place where the Jews were to enjoy rest from their labours; God likewise, did, himself, rest the seventh day from his works: yet, whoever imagined God's rest from the creation to be prefigurative of the Jews rest in Canaan? and it is not equally reasonable to say, that God's rest on the seventh day, prefigured the entrance of the Jews into Canaan, as to say, that the Jews rest in Canaan prefigured the rest mentioned by David in the Psalms.

This will equally imply, that all the following events in the uniform course of God's government, similar to any preceding ones, were designed to be prefigured by them; in which sense, it will readily be owned, that the rest of the Jews was typical of the rest of the Christians.

It is in the same manner we are to understand St. Paul, where he says, "That Christ our passover is sacrificed for us." And thus we are to understand John the Baptist, when he calls our Saviour the "Lamb of God."—There was this similitude of circumstance, that Christ was slain on the same day with the paschal lamb; that he died about the same time of the day when the priests began their lulle; that not a bone of the one or the other was broken. Add, that as the paschal lamb was without blemish, so was Christ without sin.—From these and other circumstances, the apostle applied the term passover to Christ.

Thus, also, we are to account for what St. Paul calls the baptism of the children of Israel in the cloud, and in the sea; and for the comparison betwixt the high priest entering the holy place every year, and Christ entering into heaven.

T Y P

TYPE of Constans, a formulary or model of faith, published by the emperor Constans, who being a favourer of the Monothelites, and exasperated at the little success which the ecsthesis of his uncle Heraclius had met with, published a new formulary in the manner of an edict in 648, forbidding all persons to make use of the expressions "one, or two wills in Jesus Christ."

Martin I. condemned the type in the Lateran council, anno 649, and the synod made a canon expressly against this heretical model; at which the emperor was so enraged, that he forced the pope into banishment.

TYPE, among letter-founders and printers, the same with letter. See the articles **LETTER**, and **LETTER-FOUNDER**.

TYPE is also used to denote the order observed in the intension and remission of fevers, pulses, &c.

TYPHA, in botany, a genus of plants, having no corolla: the male flowers are arranged into a cylindric amentum; the female flowers form also a cylindric amentum below the male ones; there is no pericarpium, the fruit growing together in great numbers, constitutes a cylinder, in each of which there is a single ovated seed, furnished with a style, and standing upon a seta, which seta stands on a capillary pappus.

TYPHODES, τυφοδης, or τυφος, in medicine, a kind of ardent or burning fever usually attending on erysipelas of any of the viscera. Of this disorder, according to Hippocrates, there are five species. The first is a legitimate continual fever, which impairs the strength, is accompanied with a pain of the belly, and a preternatural heat of the eyes, hinders the patient from looking steadily on any object whatsoever, and renders him unable, in consequence of the violent pain, to speak. The second species begins with a tertian or quartan fever. The patient discharges a great quantity of saliva and worms at his mouth; his eyes are painful, his feet and sometimes his whole body, are seized with soft swellings. His breast and back are now and then painful; his belly rumbles, his eyes are fierce, he spits a great deal, and his saliva sticks to his throat. The third species is known by intense pains in the joints, and sometimes over all the body; the blood contaminated by the bile, becomes hot and stagnates in the limbs. The fourth species is known by a violent tension; elevation, and heat of the abdomen, succeeded by a diarrhæa, which sometimes ends in a dropsy. The fifth species is not unlike the first. See the article **FEVER**.

TYPHOMANIA, τυφομανια, in medicine, a disorder of the brain, wherein the patient not being able to sleep, though greatly inclined thereto, lies with his eyes shut, talks absurdly, and flings himself this way and that. The typhomania is a kind of combination of

T Y T

a frenzy with a lethargy, and is much the same with coma virgil.

TYPOGRAPHY, the art of printing. See **PRINTING**.

TYPHON, in church-history, a god of the ancient Egyptians. This people admitted two principles, the one good, the other bad. Isis, Osiris, and Orus were good gods, and Typhon the evil god. To this latter they imputed tempests, inundations, earthquakes, eclipses, and all misfortunes. The ass and the crocodile were his symbols; and he had divine honours paid him in that part of Egypt called Papremis.

Typhon, according to Diodorus Siculus, was brother to Osiris, who reigned in Egypt with great justice and equity, but Typhon was a violent and cruel man. He killed his brother, and cut his body into twenty-six parts.—But Isis, the wife of Osiris, and their son Orus, put Typhon to death, by drowning him in the river Orontes. The Typhæus of the Greeks is, probably, the same as the Egyptian Typhon.

M. Jurieu has drawn a kind of parallel between Moses and Typhon. The name of Typhon, he says, signifies, in the Hebrew and Phœnician language, inundation: and this name is applicable to Moses, who caused the Egyptians, and their king, to be drowned in the Red Sea. Typhon was the grand enemy of the Egyptian gods: this respects the declaration made by God to Moses, when he instituted the passover; "Against all the gods of Egypt I will exercise judgment." Typhon joined with 72 conspirators, to kill his brother: this is Moses, who led the children of Israel out of Egypt, and governed them in the wilderness with the help of 70 elders. Typhon was the brother of Osiris: Moses was reputed the son of Pharaoh's daughter, and consequently related to the king of Egypt. Typhon, having been defeated, fled away upon an ass for seven days; here we have the flight of Moses and the Israelites, and the institution of the seventh day, or the sabbath. These are the principal circumstances of the parallel; of which the reader is left to judge.

TYRANT, *Tyrannus*, among the ancients, denoted simply a king or monarch. But the ill use several persons invested with that sacred character made of it, has altered the import of the word, and tyrant now carries with it the idea of an unjust and cruel prince, who invades the people's liberty, and rules in a more despotic manner than the laws of nature or the country do allow of.

TYROCINIUM, a noviciate, or apprenticeship, in any art or science.

TYROSIS, a disorder of the stomach, proceeding from milk coagulated therein.

TYTHES, or **TITHES**. See the article **TITHES**.

V A C

U, the twentieth letter in the alphabet, and the fifth vowel. The letter U seems to owe its origin to the V consonant, though it is absolutely as different a letter from that, as E and F. It is formed in the voice by a round configuration of the lips, and a greater extrusion of the under one; the tongue is also more canulated than in forming the O; else other things are much the same.

V is also, a numeral letter, and signifies five; and with a dash at top, thus $\bar{V}$, it signified five thousand.

The letter V, we find, was in the most ancient Greek alphabet, by the Sigeian inscription. And, as it had the force of the Hebrew Vau, so it might, probably, be formed from thence; though the figure of the letter, in the most ancient Eastern alphabets, does not approach very near it; nor is the Phœnician ∇ so very remote, as not to slip easily into it, by carrying the right-hand stroke down to the bottom of the other, before it was made to join it. The power or sound of V and F is, by most grammarians, supposed to be nearly the same; but they are widely different, in all respects, even in the vocal formation; for V is founded in a much slower and more obtuse expression of the breath, and application of the upper teeth to the under lip, than is done in pronouncing F, where the voice is more clear and acute. Besides, how very different is the sound of vulgar and fulgar? which, with many instances of the like kind, prove V and F to be very different letters.

VACANCY, in philosophy. See the article **VACUUM**.

VACANCY, in law, a post, or benefice, wanting a regular officer or incumbent.

VACANT EFFECTS, *prædia vacata*, or *vacua*, are such as are abandoned for want of an heir, after the death or flight of their former owner. A Romish benefice is said to be vacant in curia Romana, when the incumbent dies in Rome, or within twenty leagues thereof, though it be only by accident that he was there. The pope nominates to all such benefices.

VACATION, in law, is the whole time betwixt the end of one term and the beginning of another.

This word is also applied to the time from the death of a bishop, or other spiritual person, till the bishopric, or dignity, is supplied with another.

VACCINUM, Billberry, Whortleberry, or Cranberry, in botany, a genus of plants, the flower of which has a small permanent empalement sitting upon the germen; it is bell-shaped, of one petal, slightly cut into four segments at the brim, which turn backward; it has eight stamina, terminated by horned summits, having two awns on their backside which spread asunder. The germen is situated below the flower, supporting a single style longer than the stamina, crowned by an obtuse stigma; it afterwards turns to an umbilicated globular berry with four cells, containing a few small seeds.

V A C

There are five species of this plant, the first of which grows very common upon large wild heaths, in many parts of England, but is never cultivated in gardens, it being with great difficulty transplanted; nor will it thrive long when moved thither; for from many trials which I have made, by taking up the plants at different seasons with balls of earth to their roots, and planting them in gardens, I could never succeed so as to preserve the plants above two years, and those never produced any fruit, so that it is not worth the trouble of cultivating.

The fruit of this sort is gathered by the poor inhabitants of those villages which are situated in the neighbourhood of their growth, and carried to the market towns. These are by some eaten with cream or milk; they are also put into tarts, and much esteemed by the people in the north, but they are seldom brought to London. The shrub on which these grow, rises about two feet high, having many stems which are garnished with oblong leaves, shaped like those of the box-tree, but somewhat longer, and are a little sawed on their edges. The flowers are shaped like those of the arbutus, or strawberry-tree, of a greenish white colour, changing to a dark red towards the top. The fruit are about the size of large juniper-berries, and of a deep purple colour, having a flue upon them when they are untouched, like the plums, which rub off with handling.

The second sort is of a much humbler growth, seldom rising above six or eight inches high. The leaves of this are so alike that of the dwarf box, as that, at a distance, the plants are often taken for it even by persons of skill. This is an ever-green, which grows upon moory ground in several parts of the north, but it is full as difficult to transplant into gardens, as the other sort, though I have been assured by persons of credit, that they have seen this sort planted to make edgings to the borders of the gardens in Norway and Sweden, where the plants may grow much better from the cold of those climates, than they will do in England, for this is a native of very cold countries. I have several times received plants of this sort from Greenland, by the whale ships. The berries of this sort are red, and have a more agreeable acid flavour than those of the first sort. The fruit is frequently used for tarts in several of the northern counties, where the plants grow wild upon the moors.

The third sort grows naturally in Virginia and other parts of North America; this has a low shrubby stalk like the second. The leaves are small, oval, pointed, and not unlike some sorts of myrtle; they continue green all the year. The flowers come out from the wings of the leaves at every joint; their foot stalks are pretty long, and nod downwards; they sustain but one flower; they are small, white, and are succeeded by small red berries which seldom ripen here.

The fourth sort grows naturally in marshy grounds in most parts of North America. The stalks of this are slender, imbricated, and trail upon the ground; the scales are bristly; the leaves are oval, entire, and their edges turn backwards; the flowers come out from the wings of the stalk, of an herbaceous white colour, and in their native soil are succeeded by large red berries, but in England the fruit comes to perfection.

The plants of this sort are difficult to preserve in England, for they require a moorish, boggy soil, which should be covered with moss, and constantly kept wet, otherwise they will not thrive.

The fifth sort produces long slender branches, not bigger than thread, which trail upon the mossy bogs, so are often hid by the moss. These branches are thinly garnished with small leaves, about the size and shape of those of thyme, having their upper surface of a shining green colour, but are white underneath. The flowers are generally produced towards the extremity of the shoots, which are in shape like those of the former sorts, but are smaller, and of a red colour; these grow upon long slender foot-stalks, and are succeeded by round, red, spotted berries, of a sharp acid flavour, which are much esteemed by the inhabitants of the places near the bogs where they grow. Some use them for tarts, and others eat them with milk or cream.

This sort is a native of bogs, therefore cannot by any art be propagated upon dry land; but where there are natural bogs the plants may be taken up carefully, preserving some of the soil to their roots, and transplanted into the bogs in the autumn; and if they are at once fixed in the place, they will spread and propagate in great plenty, and require no farther care.

The two sorts first mentioned also propagate very fast by their creeping roots, so that when they are fixed in a proper soil, they will soon overspread the ground, for the heaths, upon which they naturally grow, are generally covered with the plants. This first sort grows with the heath, their roots intermixing together, and frequently is found upon sandy heaths in divers parts of England; but the second sort grows only upon moorish land, where, by its creeping roots, the ground is soon covered with the plants.

There are several other species of this genus, some of which are natives of Spain and Portugal, others of Germany and Hungary, and several of the northern parts of America, from whence those large fruit are brought to England, which are used by the pastry-cooks of London, during the winter season for tarts; but as all these sorts naturally grow upon swamps and bogs, they are not easy to transplant into gardens in their native country, so as to thrive, or produce fruit, therefore there can be little hopes of cultivating them to advantage in England. *Miller's Gard. Diet.*

VACUUM, VACUITY, in physics, a space empty or devoid of all matter, or body.

Whether there be any such thing in nature as an absolute vacuum; or whether the universe be completely full, and there be an absolute plenum; is a thing that has been controverted by the philosophers of all ages.

The ancients, in their controversies, distinguished two kinds; a vacuum *coacervatum*, and a vacuum *interspersum*, or *disseminatum*.

VACUUM *Coacervatum*, is conceived as a place destitute of matter: such, e. gr. as there would be, should God annihilate all the air, and other bodies within the walls of a chamber.

The existence of such a vacuum is maintained by the Pythagoreans, Epicureans, and the Atomists or Corpuscularians; most of whom assert such a vacuum actually to exist without the limits of the sensible world. But the modern Corpuscularians, who hold a vacuum *coacervatum*, deny that application; as conceiving, that such a vacuum must be infinite, eternal, and uncreated.

According, then, to the later philosophers, there is no vacuum *coacervatum* without the bounds of the sensible world; nor would there be any other vacuum, provided God should annihilate divers contiguous bodies, than what amounts to a mere privation, or nothing; the

dimensions of such a space, which the ancients held to be real, being by these held to be mere negations; that is, in such a place, there is so much length, breadth, and depth wanting, as a body must have to fill it. To suppose, that when all the matter in a chamber is annihilated, there should yet be real dimensions, is to suppose corporeal dimensions without body; which is absurd.

The Cartesians, however, deny any vacuum *coacervatum* at all; and assert, that if God should immediately annihilate all the matter, v. gr. in this chamber, and prevent the ingress of any other matter, the consequence would be, that the walls would become contiguous, and include no space at all. They add, that if there be no matter in a chamber, the walls can be conceived no otherwise than as contiguous; those things being said to be contiguous, between which there is not any thing intermediate: but, if there be no body between, there is no extension between; extension and body being the same thing: and if there be no extension between, then the walls are contiguous; and where is the vacuum? But this reasoning is built on a mistake, viz. that body and extension are the same thing.

VACUUM *Disseminatum*, or *Interspersum*, is that supposed to be naturally interspersed in and among bodies, in the pores of the same body, and in the interstices between different bodies.

It is this kind of vacuum which is chiefly disputed among the modern philosophers: the Corpuscularians strenuously asserting it; and the Peripatetics, and Cartesians, as fitly impugning it.

The great argument the Peripatetics urge against a vacuum *interspersum*, is, that there are divers bodies frequently seen to move contrary to their own nature, and inclination; and that for no other apparent reason, but to avoid a vacuum; whence they conclude, that nature abhors a vacuum; and give us a new class of motions ascribed to the gravity, and pressure of the atmosphere.

The Cartesians deny not only the actual existence, but even the possibility of a vacuum: and that on this principal, that extension being the essence of matter, or body, wherever extension is, there is matter: but mere space, or vacuity, is supposed to be extended; therefore it is material. Whoever asserts an empty space, they say, conceives dimensions in that space; that is, he conceives an extended substance in it; and therefore he denies a vacuum, at the same time that he admits it. On the other hand, the Corpuscular authors prove, not only the possibility, but the actual existence of a vacuum, from divers considerations; particularly, from the consideration of motion in general; and that of the planets, comets, &c. in particular; from the fall of bodies; from the vibration of pendulums; from rarefaction and condensation; from the different specific gravities of bodies; and from the divisibility of matter into parts.

1. It is argued, that motion could not be affected without a vacuum. — This is what Lucretius urged long ago, — *Principium quoniam cedendi nulla daret res — undique materies quoniam stipata fuisset.*

The force of this argument will be increased from the two following considerations, viz. first, that all motion is either in a straight line, or in a curve which returns into itself, as the circle, and ellipsis; or in a curve that does not return into itself, as the parabola, &c. And, secondly, that the moving force must always be greater than the resistance.

For, hence it follows, that no force, even though infinite, can produce motion where the resistance is infinite; consequently, there can be no motion either in a straight line, or a non-returning curve; because, in either of those cases, the protrusion, and consequently the resistance, would be infinite. — There remains, therefore, only the motion in a revolving curve practicable; this must either be a revolution upon an axis, or an annular motion round a quiescent body; and consequently, all motion must be in circles geometrically true; and the revolving bodies must either be spheres, spheroids, cylinders, or portions of them, exactly geometrical; otherwise, the revolutions in a plenum would be

be impossible: but such motions, or such figured bodies, we do not know in nature. Therefore there is a vacuum.

2. The motions of the planets and comets, demonstrate a vacuum: thus Sir Isaac Newton says, —“ That there is no such fluid medium as æther, to fill up the porous parts of all sensible bodies, as the air and interstellar parts, and so make a plenum, seems probable; because the planets and comets proceed with so regular and lasting a motion, through the celestial spaces, both from and to all parts: for hence it appears, that those celestial spaces are void of all sensible resistance, and consequently of all sensible matter. For the resisting force of fluid mediums, arises partly from the attrition of the parts of the medium, and partly from the inactivity of matter. — Now, that part of the resistance of any medium, which arises from the tenacity, or attrition of its parts, may be lessened by dividing the matter into smaller parts, and by rendering those parts more smooth and slippery: but that part of the resistance which arises from the inactivity of matter, is always in proportion to the density of the matter; nor can it be diminished by dividing the matter, nor by any other means, except by diminishing the density thereof.”

Consequently, if the celestial regions were as dense as water, or as quicksilver; they would resist almost as much as water or quicksilver; but if they were perfectly dense, without any interspersed vacuity, though the matter were ever so fluid and subtle, they would resist more than quicksilver does; a perfectly solid globe, in such a medium, would lose above half its motion in moving three lengths of its diameter; and a globe not perfectly solid, such as the bodies of the planets and comets are, would be stopped still sooner. Therefore, that the motion of the planets and comets may be regular, and lasting, it is necessary the celestial spaces be void of all matter, except perhaps some few, and much rarified effluvia of the planets and comets, and the passing rays of light.”

3. The same great author deduces a vacuum also from the considerations of the weights of bodies; thus: “ All bodies about the earth gravitate towards the earth; and the weights of all bodies, equally distant from the earth's center, are as the quantities of matter in those bodies. If the æther, therefore, or any other subtle matter, were altogether destitute of gravity, or did gravitate less than in proportion to the quantity of its matter; because, as Aristotle, Des Cartes, and others argue, it differs from other bodies only in the form of the matter; the same body might, by the change of its form, gradually be converted into a body of the same constitution with those which gravitate most in proportion to the quantity of matter: and, on the other hand, the most heavy bodies might gradually lose their gravity, by gradually changing their form; and therefore the weights would depend upon the forms of bodies, and might be changed with them; which is contrary to all experiment.”

4. The descent of bodies proves that all space is not equally full; for the same author goes on, “ If all spaces were equally full, the specific gravity of that fluid, with which the region of the air would in that case be filled, would not be less than the specific gravity of quicksilver or gold, or any other the most dense body; and therefore neither gold, nor any other body, could descend therein. For bodies do not descend in a fluid, unless that fluid be specifically lighter than the body. — But by the air pump, we can exhaust a vessel, till even a feather shall fall with a velocity equal to that of gold in the open air: the medium, therefore, through which this feather falls, must be much rarer than that through which the gold falls in the other case.”

“ The quantity of matter, therefore, in a given space, may be diminished by rarefaction: and why may not it be diminished in infinitum? Add, that we conceive the solid particles of all bodies to be of the same density; and that they are only rarefiable by means of their pores: and hence a vacuum evident follows.”

5. “ That there is a vacuum, is evident from the vibrations of pendulums: for since those bodies in places out of which the air is exhausted, meet with no resistance to retard their motion, or shorten their vibrations;

it is evident there is no sensible matter in those spaces, or in the occult pores of those bodies.”

As to what Des Cartes urges of his *materia subtilis*, that its tenuity prevents its resistance from being sensible, and that a small body sticking against a greater, cannot in the least prove, or resist the motion of that other; but is reflected back again with all its momentum: it is contrary to all experience. For Sir Isaac proves, that the density of fluid mediums, is proportionable to their resistances, very nearly; and that they are exceedingly mistaken, who suppose the resistance of projectiles to be infinitely diminished, by dividing the parts of the fluid, even in infinitum. When, on the contrary, it is clear the resistance is but little diminished by the subdivision of the parts; and that the resisting forces of all fluids are nearly as their densities. — For why should not the same quantity of matter, whether divided into a greater number of subtle parts, or into a few larger ones, have the same resisting force? If then there were no vacuum, it would follow, that a projectile moving in the air, or even in a space whence the air is exhausted, should move with as much difficulty as it would in quicksilver; which is contrary to experience.

6. That there are interspersed vacuities, appears from matter's being actually divided into parts, and from the figures of those parts: for, on supposition of an absolute plenitude, we do not conceive how any part of matter could be actually divided from that next adjoining, any more than it is possible to divide actually the parts of absolute space from one another: for by the actual division of the parts of a continuum from one another, we conceive nothing else understood, but the placing those parts at a distance from one another, which, in the continuum, were at no distance from one another: but such divisions between the parts of matter, must imply vacuities between them.

7. As for the figures of the parts of bodies, upon the supposition of a plenum, they must either be all rectilinear, or all concavo-convex; otherwise, they would not adequately fill space; which we do not find to be true in fact.

8. The denying a vacuum, supposes what it is impossible for any one to prove to be true; viz. that the material world has no limits.

Since then the essence of matter does not consist in extension, but in solidity, or impenetrability, the universe may be said to consist of solid bodies moving in a vacuum: nor need we at all fear, lest the phenomena of nature, most of which are plausibly accounted for from a plenitude, should become inexplicable when the plenum is set aside. — The principal ones, such as the tides; the suspension of the mercury in the barometer; the motion of the heavenly bodies, and of light, &c. are more easily and satisfactorily accounted for from other principles.

VACUUM BOYLEANUM is sometimes, though improperly, used to express the approach to a real vacuum, by means of an air pump. See the last article, AIR, and PUMP.

VADARI, in the civil-law, denotes a person to pledge, undertake, or give security, in behalf of another, that he shall, on a certain day, appear in court to prosecute or answer.

VADE-MECUM, or VENI-MECUM, a Latin phrase, used, in English, to express a thing that is very handy and familiar, and which one usually carries about with them; chiefly applied to some favourite book.

VADIMONIUM, in the civil-law, a promise, or bond, given for appearance before the judge upon a day appointed.

VAGABOND, in law. See VAGRANTS.

VAGINA, properly signifies a sheath, or scabbard; and the term vagina is used, in architecture, for the part of a terminus, because resembling a sheath, out of which the statue seems to issue.

VAGINA, in anatomy, a large canal, formed of a robust and strong membrane, and reaching from the external orifice, or os pudendi, in women, to the uterus.

The vagina is usually about six or seven fingers breadth long; but is very distensible, and capable of great dilata-

tion;

tion; its orifice is narrower than any other part, and closed by a sphincter muscle: its substance is membranaceous, and rugose internally, and furnished with abundance of nervous papillæ; and to this is owing its quick sensation; externally it is muscular, where it is enabled to embrace the penis more closely in coitu. The rugæ are largest in maids, and especially in the anterior part of the vagina; in married women they are much fainter, and seem as if worn down; and in women who have born children, they are almost entirely obliterated. Their use is to encrease the pleasure in coitu, both to the man and to the woman; and to render the part capable of the necessary dilatation in parturition.

About the mouth of the vagina are found certain lacunæ, or small orifices, capable of admitting a bristle: they proceed from the glandulæ substratæ, and serve to secrete a liquor for lubricating the vagina, and for stimulating to venery.

The use of the vagina is to receive the penis in coition, to emit from the womb the menstrual discharges, the foetus, the secundines, and lochia.

VAGINALIS, or ELYTROIDES, in anatomy. See ELYTROIDES.

VAGRANTS, in law, are described to be persons pretending to be patent-gatherers, or collectors for prisons, and wander about for that end; among which are included all fencers, bear-wards, common players of interludes, minstrels, jugglers; all persons pretending to be gypsies, or wandering in the habits of such, or pretending skill in physiognomy, palmistry, or the like, or to tell fortunes; all such as use any subtle craft, unlawful games or plays; or, being able in body, run away, leaving their wives or children to the parish; all persons who cannot otherwise maintain themselves, that loiter about and refuse to work for the usual wages; and all other persons wandering abroad and begging, &c.

It is enacted, that where any such vagrants shall be found in a parish, the constable, or other officer, is immediately to apprehend them, and carry them before some justice of the peace, who shall examine the persons on oath, as to their condition, and places of abode; and thereupon order them to be sent by pass to the place of their last legal settlement; or if that cannot be known, to the place of their birth. The justice is to give the constable a certificate ascertaining how, and in what manner, they shall be conveyed, &c. And justices of the peace in their sessions, have power to appoint rates for passing of vagrants, at so much per mile. All constables are to make searches for these people before every quarter-sessions; and in case any persons permit vagrants to lodge in their houses, barns or out-houses, and do not carry them before the next justice, or give notice to some constable, or other parish-officer, so to do, they shall forfeit a sum not above 40s. or under 10s. Also, if any charge be brought upon any place by means thereof, the same may be levied by distress and sale of the offender's goods; for want of which he shall be committed to the house of correction, and there set to hard labour for three months.

VAGUM, or PAR VAGUM, in anatomy, the eighth pair of the nerves arising from the medulla oblongata.

VAIR, in heraldry, a kind of fur, consisting of divers little pieces, argent and azure, resembling a Dutch U, or a bell-glass.

Vairs have their point azure opposite their point argent, and the base argent to the base azure.

VAIRY, VAIRE, VERRY, or VARRY, in heraldry, expresses a coat, or the bearings of a coat, when charged or chequered with vairs: and hence, vairy-cuppy, or vairy-tally, is a bearing composed of pieces representing the tops of crutches.

VALENTINIANS, in church history, a sect of Christian heretics, who sprung up in the second century, and were so called from their leader Valentinus.

This sect was one of the most famous, and most numerous among the ancients. Valentinus, who was the author of it, was an Egyptian, and began their to teach the doctrine of the Gnostics. His merit made him aspire to the episcopacy; but, another having been preferred before him, Valentinus, enraged at this denial, and resolved to revenge himself of the affront given him,

departed from the doctrine of the Church, and revived old errors. He began to preach his doctrine in Egypt, and from thence coming to Rome, under the pontificate of pope Hyginus, he there spread his errors, and continued to dogmatize till the pontificate of Anicetus, that is, from the year 140 to 160.

Of all the Gnostics none formed a more regular system than Valentinus. His notions were drawn from the principles of the Platonists. The Æons were attributes of the Deity, or Platonic ideas, which he realized, or made persons of them, to compose thereof a complete Deity, which he called Pleroma, or Plenitude; under which was the Creator of the world, and the angels, to whom he committed the government of it. The most ancient heretics had already established those principles, and invented genealogies of the Æons: but Valentinus, refining upon what they had said, placed them in a new order, and there-to added many fictions. Their system was this: the first principle is Bythos, that is Depth: it remained for many ages unknown, having with it Ennoe, i. e. Thought, and Sige, i. e. Silence. From these sprung the Nous, or Intelligence, which is the only son, equal to it alone, and capable of comprehending it; whose sister is Aletheia, that is, Truth. This is the first quaternity of Æons, which is the source and original of all the rest. For Nous and Aletheia produced the Word and the Life; and from these two proceeded Man and the Church. This is the second quaternity of the eight principal Æons. The Word and the Life, to glorify the Father, produced five couple of Æons: Man and the Church formed six. These thirty Æons bear the name of attributes and compose the Pleroma, or Plenitude of the Deity. Sophia, or Wisdom, the last of these Æons, being desirous to arrive at the knowledge of Bythos, gave herself a great deal of uneasiness, which created in her Anger and Fear, of which was born Matter. But the Horos, or Bounder, stopped her, preserved her in the Pleroma, and restored her to perfection. Then she produced the Christ, and the Holy Spirit, which brought the Æons to their last perfection, and made every one of them contribute their utmost to form the Saviour. Her Enthymese, or Thought, dwelling near the Pleroma, perfected by the Christ, produced every thing that is in the world, by its divers passions. The Christ sent into it the Saviour, accompanied with angels, who delivered it from its passions, without annihilating it; and from thence was formed corporeal matter, which was of two sorts; the one bad, arising from the passions; the other good, proceeding from conversion, but subject to the passions.

The disciples of Valentinus did not strictly confine themselves to his system. They took a great deal of liberty, in ranging the Æons according to their different ideas, without condemning one another upon that account. But what is most abominable is, that from these chimerical principles they drew detestible conclusions as to morality: for, because spiritual beings could not perish, being good by nature, hence they concluded, that they might freely, and without scruple, commit all manner of actions, and that it was not at all necessary for them to do good; but above all, they believed continence to be useless. We have, in Clemens Alexandrinus, an extract of a letter of Valentinus, in which he maintains, that God does not require the martyrdom of his children, and that, whether they deny or confess Christ before tyrants, they shall be saved. If they believed that good works were necessary, it was only for animal men. Some believed, that baptism by water was superfluous: others baptized in the name of the unknown Father, of the truth the mother of all, of him who descended in Jesus, of the light redemption, and community of powers. Many rejected all outward ceremonies.

In fine, the errors of the Valentinians were wholly incompatible with the Christian doctrine. If they did not destroy the unity of God, they made of him a monstrous composition of different beings. They attributed the creation to another principle: they set up good and bad substances by nature. Jesus Christ, according to them, was but a man in whom the celestial Christ descended. The Holy Ghost was but a simple divine virtue. There is no resurrection of the body. Spiritual men do not

merit eternal life; it is due to them by their nature; and do what they will, they can never miss of it; as material men cannot escape annihilation, although they live an unblameable life.

VALERIAN, in botany, a genus of plants, with channelled stalks; the leaves are in pairs, each leaf being composed of a number of long narrow sharp-pointed segments, indented about the edges, of a dull green colour, set along a middle rib, which is terminated by an odd one; producing, on the tops of the stalks, umbel-like clusters of small monopetalous flowers, each of which is divided into five segments, set in a very little cup, and followed by a single naked seed winged with down: the root consists of tough strings with numerous smaller threads, matted together, issuing from one head, of a dusky brownish colour approaching to olive. It is perennial, and grows wild in dry mountainous places.

Another species, or variety, or wild valerian, is met with in moist watery grounds, distinguishable by the leaves being broader and of a deep glossy green colour. Both sorts have been used indiscriminately: but the mountain sort is by far the most efficacious, and is therefore expressly ordered for the officinal species by the London college.

The mountain valerian root has a strong not agreeable smell, and an unpleasant warm bitterish sabacid taste: the strength of the smell and taste is the only mark to be depended on of its genuineness and goodness. It is a medicine of great esteem in the present practice against obstinate hemicranæ, hysterical, and the different kinds of nervous disorders, and is commonly looked upon as one of the principal antispasmodics. Calugna reports, that he was cured by it of an inveterate epilepsy after many other medicines had been used in vain: on more extensive trials it has been found, in some epileptic cases to effect a cure, in several to abate the violence or frequency of the fits, and in many to prove entirely ineffectual: oftentimes, it either purges, or operates by sweat or by urine, or brings away worms, before it prevents a fit. The dose of the root in powder is from a scruple to a dram or two, which may be repeated, if the stomach will bear it, two or three times a day.

The powdered root, infused in water or digested in rectified spirit, impregnates both menstrua strongly with its smell and taste, and tinges the former of a dark brown, the latter of a brownish red colour. Water distilled from it smells considerably of the root, but no essential oil separates though several pounds be submitted to the operation at once: the extract obtained by inspissating the watery infusion, has a pretty strong taste, disagreeably sweetish and somewhat bitterish: the spirituous extract is less disagreeable, and more perfectly resembles the root itself: the quantity of watery extract is about one fourth the weight of the root; of the spirituous, about one eighth. Tinctures of it are prepared in the shops, by digesting four ounces of the powdered valerian in a quart of proof spirit; in the same quantity of the volatile aromatic spirit; in three quarts of mountain wine, with the addition of an ounce of Virginian snakeroot, and half an ounce of rosemary tops. The root in substance, however, is generally found to be more effectual than any preparation of it. Among the materials I have made trial of for covering its flavour, mace seemed to answer the best. *Lewis's Materia Medica*.

VALET, a French term, used as a common name for all domestic men servants, employed in the more servile officers, as grooms, footmen, coachmen, &c. But with us, it is only used in the phrase *valet de chambre*, which is a servant whose office is to dress and undress his master, &c.

VALET, in the manage, a stick armed at one end with a blunted point of iron, to prick and aid a leaping horse.

VALETUDINARY, *Valetudinarius*, among medical writers, denotes a person of a weak and sickly constitution, and frequently out of order.

VALID, in law, an appellation given to acts, deeds, transactions, &c. which are clothed with all the formalities requisite to their being put into execution, and to their being admitted in a court of justice.

VALLAR CROWN, *valaris corona*, in Roman anti-

quity, the same with that otherwise called *castrensis*. See **CROWN**.

VALUE, *Valor*, in commerce, denotes the price or worth of any thing: hence the intrinsic value denotes the real and effective worth of a thing, and is used chiefly with regard to money, the popular value whereof may be raised and lowered, at the pleasure of the prince; but its real, or intrinsic value, depending wholly on its weight and fineness, is not at all affected by the stamp or impression thereon.

Value in bills of exchange, is used to signify the nature of the thing (as ready money, bills, debts, merchandizes, &c.) which is given, as it were, in exchange for the sum specified in the bill. From four different manners of expressing this value, some distinguish four kinds of bills of exchange. The first bears value received, simply and purely, which comprehends all kinds of value; the second value received in money or merchandize; the third value of myself; and the fourth understood. See the article **BILL**.

VALVE, *Valvula*, in hydraulics, pneumatics, &c. is a kind of lid, or cover of a tube or vessel, so contrived as to open one way; but which, the more forcibly it is pressed the other way, the closer it shuts the aperture; so that it either admits the entrance of a fluid into the tube or vessel, and prevents its return; or admits its escape, and prevents its re-entrance. See **PUMP**.

The word is formed from the Latin *valvæ*, folding doors.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of body to afford a passage to certain humours going one way, and prevent their reflux towards the place from whence they came. The veins and lymphatics are furnished with valves, which open towards the heart, but keep close towards the extremities of those vessels; that is, they let the blood and lymph pass towards the heart, but prevent their returning towards the extreme parts from whence they came.

The heart has also its valves, placed at the entrance of the vessels rising out of it. Those at the entrance of the vena cava, and pulmonary vein, let the blood pass on to the heart, and prevent its return: on the contrary those at the entrance of the aorta, and pulmonary artery, let the blood pass out of the heart, and prevent its flowing back again. See the articles **HEART** and **ARTERY**.

The upper and, as it were, the lid of the isthmus, between the testes and the first vermicular process of the cerebellum, is called the *valvula magna*, or the great valve of the brain. Its use is to prevent the lymph from falling on the nerves, at the base of the cranium. See **BRAIN**.

The colon has a thick valve to prevent the excrements from passing into the ilion, and several other valves to retard the descent of the excrements.

VAN, **VANT**, or **VAUNT**, a term derived from the French *avant*, or *avaunt*, signifying *before*, or *foremost* of any thing: thus we say, the van-guard of an army, &c.

VANELLUS, the **LAPWING**, in ornithology, the black-breasted tringa, with a hanging crest.

This species is about the size of the common pigeon; the head is small, but very beautiful, a little depressed on the crown, but not at all on the sides; the eyes are bright and piercing; the head is elegantly variegated, and is ornamented with a beautiful crest hanging over the hinder part of the neck.

VANES, on mathematical instruments, are sights made to move and slide upon cross-staves, fore-staves, quadrants, &c.

VANILLA, or **VANELLOE**, in commerce, implies the fruit of a climbing plant growing in many parts of the Spanish West-Indies. It is a long flattish pod, containing under a wrinkled brittle shell, a reddish brown pulp with small shining black seeds.

Vanelloes have an unctuous aromatic taste, and a fragrant smell like that of some of the balsams heightened with musk. They are used chiefly in perfumes; scarcely ever, among us at least, in any medicinal intention. They often make a part in the composition of chocolate, to give it an agreeable flavour.

VAPOR, or **VAPOUR**, in metreology, a thin viscidle of water, or other humid matter, which ascends to a certain

certain height in the atmosphere, where it is suspended till it returns in the form of rain, hail, snow, or the like.

An assemblage or number of particles, or vesicles of vapour, constitutes what we call a cloud.

The ingenious Dr. Hamilton, professor of philosophy in the university of Dublin, has explained the ascent of watry vapours, and other phænomena of the atmosphere, on a principle very different from any that has hitherto been used on this occasion; and removed the difficulties which before attended this difficult, and interesting enquiry. We shall therefore lay before our readers the Doctor's account, which appeared in the *Philosophical Transactions*, Vol. LIV.

"In all the accounts, says the doctor, I have met with, fire, or heat and rarefaction, by which watery vapours are supposed to become specifically lighter than air, are made to be the principal, if not the only causes of their ascent into the atmosphere. Doctor Niewentyt, and some others supposed, that the particles of fire, by adhering to those of water, make up molecular or small bodies specifically lighter than air. And Doctor Hally thought that by the action of heat the particles of water are formed into hollow spherules filled with a finer air, highly rarefied, so as to become specifically lighter than the external air. This last was the opinion most commonly received as Doctor Desaguliers tells us in his dissertation on this subject (published in the *Philosophical Transactions*, in the year 1729) in which he examines and refutes the two former opinions, and endeavours to establish his own. He ascribes the ascent of aqueous vapours to their being turned into an elastic steam, and always rarefied more than the air by the degrees of heat, to which bodies are usually subject in the different seasons of the year.

"This opinion, I find, has been as ill received by subsequent writers, as the former ones. Mr. Clare, in his *Treatise on the Motion of Fluids*, has brought many objections against it; as Mr. Rowning has also done in his *System of Natural Philosophy*, not long since published; who says, that the cause of the ascent of vapours has been much disputed, but not yet determined by philosophers, and owns that he cannot think of any true principle of philosophy upon which it may be accounted for.

"I shall not here repeat the objections made by those gentlemen, but must beg leave to add the two following, which, among many others that might still be urged, they have not taken notice of.

"First, If heat was the only cause of evaporation, water in a close room would evaporate faster than when exposed in a colder place where there is a constant current of air, which is contrary to experience.

"Secondly, The evaporation of water is so far from depending on its being rarefied by heat, that it is carried on even whilst water is condensed by the coldness of the air. For water is gradually condensed by cold, 'till the moment it freezes; and since it evaporates even when frozen into hard ice, it must evaporate in all the lesser degrees of cold. Mr. Boyle having counterpoised a piece of ice in a scale, hung it out in a frosty night, and found next morning that it lost considerably of its weight by evaporation, "Who would have thought, says he, that "so extremely hard and cold a body would evaporate "so fast in the clear air of a freezing night?" and since that time others have observed the same thing; which fact seems to be an unanswerable objection to all the accounts in which rarefaction by heat is made to be the chief, if not the only cause of evaporation; and therefore we must have recourse to some other principle to assist us in accounting for this phænomenon.

"As the author of nature does not employ in his works a greater variety of causes than is absolutely necessary, it is the business of natural philosophy to reduce as many phænomena as may be, to some general well-known cause; and this is to be done by comparing the phænomena together in their several circumstances, in which if they are found to agree, they are then to be considered as effects of the same kind, and ascribed to the same cause; by which means, the causes, whose ex-

istence is already proved, will be rendered more general, and our knowledge more extensive. Now, as the suspension of the particles of water in air, of salt in the waters of the ocean, and of other heavy bodies in the fluids that dissolve them, seem to be phænomena of the same kind, we might reasonably suppose, that they arise from the same cause, and that what we call evaporation is nothing more than a gradual solution of water in air. But that I may not propose this merely as an hypothesis, I shall endeavour to prove the truth of it, by considering the nature of solution in general and comparing its properties and effects with those of evaporation.

"By solution we understand, such an intimate union between the particles of a body and those of a fluid, that the whole shall appear an homogeneous mass, as transparent as the fluid was before such union, and shall so continue, till some external cause produces a change. The nature of solution has been explained by the writers on chymistry in this manner; when the particles of any body surrounded by a fluid are less strongly attracted by each other than by the fluid, they must separate from each other, and join themselves to those of the fluid, and remain suspended therein: thus various salts are dissolved in water, essential oils in spirits of wine, gold in aqua regia, mercury, silver and other metals in other acid spirits; and indeed it seems to be with great appearance of reason, that the attraction between the minute particles of different bodies (of which we have so many other instances) is assigned as the cause of that union between them, which we experience in solutions; the chief properties of which I shall now mention, so far as may be necessary for the purpose, to which I mean to apply them.

"In most cases a dissolving fluid, or menstruum as chymists call it, will dissolve or take up only a certain proportion of the body immersed, and if then any more of the same body be added, it will precipitate, or fall to the bottom, and then the fluid is said to be saturated with the body it has dissolved; yet a fluid which is saturated with one body may afterwards dissolve others of different kinds, and keep all their particles suspended together.

"When any menstruum has entirely dissolved a body, it will continue as transparent as it was before; the cause of which may be assigned from what Sir Isaac Newton discovered by experiments, viz. that the particles of bodies must be of a certain size or bigness to cause any reflection or refraction of the rays of light at their surfaces to which opacity is owing; whence he gives the reason, why some bodies are opaque and others transparent. He also observes, that the most opaque bodies (such as metals) being dissolved in an acid menstruum, and thereby reduced to their ultimate and smallest particles, do not take away the transparency of the menstruum.

"Hence we may always know how to distinguish a solution from a mixture. For, if a body be reduced to powder and thrown into a fluid that will dissolve it, and they are then shaken suddenly together, the fluid will continue somewhat opaque, till the solution be effected, or till what remains undissolved fall to the bottom; for in this case, the particles are not at first reduced to their smallest size, as they always are in a solution. I think therefore we may consider the transparency of an heterogeneous fluid (or one that contains in it particles of another body) as the criterion of a true solution; and where that is wanting, it is only a mixture; as when water and air appear together in froth, or in a cloud, or a thick mist, it is only a mixture of those bodies, and not a solution of one in the other.

"This much being premised concerning the nature of solutions in general, I proceed to the proof of what I proposed; and in order to this, I shall shew that there is a mutual attraction between water and air, the same that we observe between the particles of any two bodies, one of which dissolves the other. I shall then compare in several instances, the properties and effects of common solutions with those of evaporation; that from the exact resemblance between these two phænomena, it may appear that they are natural operations or effects of

a like kind, and therefore to be explained upon the same principle, or ascribed to the same cause. Thence I shall shew, how the ascent of vapours, and several other phenomena of the atmosphere may be accounted for. And lastly, I shall add something on the rising of steam from boiling liquors, and shew wherein it differs from common evaporation.

"I am first to prove that there is an attraction between the particles of air and water. It is well known, that all water contains a considerable quantity of air, that retains its elasticity by means of which it may be separated from the water by boiling and including it in an exhausted receiver. And it has been proved by experiments, that air extricated from water by boiling, and restored to its usual density, will occupy a space greater than that possessed by the water in which it was contained. Now since it is allowed that the particles of so heavy a body as gold are suspended in aqua regia by their attraction towards the particles of that fluid, it seems reasonable to suppose, that so light and elastic a body as air must be retained under water by a like force, without which it would always ascend to the surface and escape. But that there is really such an attractive force between air and water, has been fully proved by the following experiment.

"Let an oil-flask be filled almost full with water, deprived of its air, as much as may be; let the mouth of it be then stopped, until the neck being inverted is immersed in a vessel of water; a bubble of air will then ascend into the upper part of the flask. When things have stood in this way for some days, the water will be found to have absorbed the whole bubble of air (if it was not too large) and entirely filled the flask. But if the bubble was too large, part of it will be left; for the water, after some time, will absorb no more air, being then sufficiently saturated with it. It is observable that a part of the included air enters pretty quickly into the water at first, but what remains afterwards makes its way in but very slowly. This experiment shews that water, when deprived of its air, will again draw the air gradually into its pores; just in the same manner as a lump of dry sugar will draw up water into its pores, which will ascend pretty quickly at first, but very slowly after some time. We have reason therefore to conclude, that there is the same kind of attraction between air and water, that there is between water and any dry porous body that will imbibe it.

"As water contains a considerable quantity of air, so does air contain a good deal of water, even when we think it quite pure and dry; as appears from the moisture drawn from it by dry salt of tartar, in such quantity as to make the salt become entirely fluid. Now since the air is an heterogeneous fluid containing in it particles of another body, and yet retaining a perfect transparency, which is the criterion of a true solution in other cases; why should we not infer from analogy, that in this case also there is a true solution of water in air.

"But the truth of this will be confirmed by farther comparing the properties of common solutions with those of evaporation; which I shall now do in several instances.

"First; when a body is immersed in a fluid that dissolves it, for instance a lump of salt in water, we see the salt soon begin to dissolve, and impregnate with its particles the water that surrounds it, which will then appear thick and loaded, and if the water be at rest the solution will proceed very slowly; but if it be stirred about, the salt will soon be entirely dissolved. How exactly does this correspond with what Dr. Halley remarked in an experiment he made on the evaporation of water in a close room? (*Philos. Trans.* N^o. 192.) "The same observations says he, do likewise shew an odd quality in the vapours of water, which is, that "of adhering to the surface that exhales them, which "they clothe as it were with a fleece of vaporous "air, which once investing it, the vapour rises afterwards "in much less quantity." Here we see, that the air which lay at rest over the water appeared thick and loaded with the aqueous particles, and then the evaporation proceeded very slowly; just as the water that lies about the salt, appears thick and loaded, and while it conti-

nues at rest, the salt is dissolved but slowly. He also observes on the same occasion, that evaporation is vastly promoted by a current of fresh air passing over the exhaling surface: and this I have no doubt happens for the same reason that solution is greatly promoted by agitation, which continually brings fresh particles of the fluid into contact with the body it dissolves, in the place of those that have been already saturated.

"Secondly; into a glass of clear cold water throw a lump of any salt which is soluble in it, and when it has stood a little time, shake the glass or stir the water very gently, and the water which is saturated with the salt will rise up among the rest of the water in curled wreaths or long striæ, which will render the water somewhat opaque; causing it to refract in different directions the light of an object seen through it, and will make the object appear to have a tremulous motion; this will continue until all parts of the water are equally impregnated with the salt, and then its transparency will be restored. As the parts of the water which are impregnated with the salt are of different densities from the rest, while they are mixing together, they must occasion those refractions and this apparent tremulous motion, which will cease as soon as all the water becomes of the same density. The very same appearances will attend the mixing together of any two fluids of different densities, and which will thoroughly incorporate with each other.

"In like manner, when smoke or steam, issuing from the pipe of a boiling vessel, first rises into the air, it appears in curled wreaths and renders the air opaque; but as soon as it is entirely dispersed, the transparency is restored. Thus also in a calm, hot, sun-shine day, when we look along a moist piece of ground, the air and any object seen through it appear to have a tremulous motion, like that which we observe in an object, seen thro' two fluids which are mixing together. Now, as the vapours rise here in great abundance and the air has but little motion, those parts of it that are much impregnated with aqueous particles are mixed gradually with the air that is drier and of a different density; which will occasion refractions of the light, and that apparent tremulous motion, just now mentioned; and in this case, the solution of water in air (if I may yet venture to call it by that name) is carried on in a manner visible to the eye, as solutions are in other fluids. The same tremulous undulating motion is more observable, when we look in warm weather through a telescope, which magnifies the vapours floating in the air: and from this kind of refraction the twinkling of the stars seems to arise; with this difference only, that the watery refracting particles in the day-time are passing into a state of solution, whereas the vapours already dissolved are by the cold of the night beginning to precipitate, and return into particles large enough to cause refractions in the light of the stars.

"Thirdly; heat promotes, and cold in some measure stops or checks both solution and evaporation. Very hot water will dissolve salt sooner and in a greater quantity than cold water; and if a strong solution of salt be made in hot water, the water when cold will let go some of the salt before dissolved, which will fall to the bottom in small particles or shoot into crystals. Just so will water evaporate faster in warm than in cold air; and the aqueous vapours suspended in the air during the heat of the day, fall down at night and form themselves into drops of dew, or if the night be very cold appear next morning crystalized in a hoar-frost. And thus if in a hot day a bottle be filled with any very cold liquor, and exposed to the warm air, which to us seems very dry, a dew will be soon formed on the outside of the bottle; for the air about it becoming cold will let go part of its moisture, which will be attracted to the surface of the glass; for the same reason a dew is formed on the inside of the windows of a warm room which on their outside are exposed to the cold air. Hence also we may observe, that as there cannot be so continual and copious an evaporation in cold weather, the air will then be generally clearer than it is in hot weather.

"Heat seems to promote solution, because it expands bodies, and thereby enlarges their pores, and lessens the cohesive attraction of their particles; so that a body,

when hot, will more easily admit a dissolving fluid into its pores, and its particles not cohering together so strongly, as when cold, will more readily quit each other, and unite themselves to the particles of the fluid by which they are attracted; and for the same reason heat will also promote the evaporation of fluids.

" But fourthly; The quantity of a body dissolved, and of a fluid evaporated, in a given time, depends (*ceteris paribus*) on its quantity of surface. Thus a body reduced to powder is sooner dissolved than when it is in a solid form; and thus smoke or steam (which is water reduced to very small particles by heat) is much sooner dispersed and incorporated with air, than water in its usual form.

" Fifthly; chymists observe, that when sea-salt sal ammoniac, or nitre, is dissolved in water, or essential oils in spirit of wine, some degree of cold is produced in the immediate act of solution; and the quicker the solution, the greater is the cold. By dissolving pounded ice, or rather snow (whose particles have a greater surface) in spirit of nitre, a degree of cold has been produced so great as to freeze quick-silver. Cold is likewise produced in the act of evaporation. For if spirit of wine, or æther, having the same temperature with the air, be rubbed lightly with a feather over the ball of a thermometer, it will sink as the spirit evaporate; and the quicker they evaporate, the faster will the thermometer sink; thus I have made water freeze in a thin glass merely by the evaporation of æther promoted by a current of air. Water will likewise produce cold, if it be used instead of spirits, provided its evaporation be promoted by a strong current of air. That cold is produced by the evaporation of water appears from the practice of sailors, who, in hot climates, cool their liquors by wrapping the vessels in wet cloths, and hanging them up where they are much exposed to the wind and sun, and wetting the cloths again when they become dry.

" This observation shews a very remarkable agreement between the natures of solution and evaporation: How the cold is produced in either case, I cannot pretend to say; but I must beg leave just to apply this fact, to account for a thing which I believe most people have taken notice of. If we rub Hungary-water, or any other volatile spirit over our hand, it will feel much colder than water, though they be both of the same temperature, and will both feel equally cold, if we dip our finger into each. The reason of which is, that the spirit evaporating much quicker than the water, produces thereby a greater degree of cold. And so æther, if it be applied in the same way, will feel colder than any other spirit, on account of its more sudden evaporation.

" Sixthly; it is known, that rectified spirit of wine, when purged of air, will imbibe a large bubble of air in a much shorter time than water will do, and I have myself experienced the truth of this, which shews that there is a stronger attraction, or affinity (as the chymists call it) between spirit of wine and air, than between water and air, and since the spirit evaporates much faster than the water, I think we may conclude from hence, that the evaporation of fluids arises from an attractive force between their particles and those of air. But here it must be observed that the spirit is not only more strongly attracted by the air than water is, but, being also more easily rarefied by heat, its particles seem to cohere together more slightly than those of water, and therefore may be more easily separated by the attraction of the air.

" Seventhly; if into any menstruum we throw a body, which it dissolves, and afterwards add another, to which the menstruum has a greater affinity than it has to the first, it will dissolve the second body, and let go the first, which will be precipitated and fall to the bottom. In the very same manner will a fluid let go the air it contains, upon the addition of another body to which it has a greater affinity than it has to the air. Thus if to well rectified spirit of wine we add an equal quantity of clear water, these fluids (which so readily incorporate) having a greater affinity to each other than to the air they contain, will let go a great part of that

air, which will rise to the top, or adhere in small bubbles to the sides of the vessel. This, I think, shews that air is contained in these fluids, in the same manner that the particles of a body are contained in a menstruum that dissolves it; and hence I conclude that the air which is imbibed by any fluid is, properly speaking, dissolved in that fluid; and consequently that any fluid which evaporates, or is imbibed by the air, is also, properly speaking, dissolved in air. Upon this principle we may say, that water is drawn out of the air by dry salt of tartar, from its having a greater affinity to that salt than to the air.

" I should not have been so tedious in comparing together the natures of solution and evaporation in so many instances, but that it gave me an opportunity at the same time of explaining some of the phenomena that I at first intended to consider; which explanations I believe will be admitted, if I am right in the main point I have endeavoured to prove. And really when we consider how exactly solution and evaporation agree, in their several appearances, properties and effects, I think we must be convinced that they are natural operations of the same kind, and that what we call evaporation, is nothing more than a gradual solution of water in air, produced and promoted by the same means (to wit) attraction, heat, and motion, by which other solutions are effected.

" I shall now endeavour to account for several phenomena of the atmosphere upon this principle, which will be still further confirmed, if it be found to answer the purpose to which it is applied.

" The lowest part of the air being pressed by the weight of the atmosphere against the surface of the water, and continually rubbing upon it by its motion, has thereby an opportunity of attracting and dissolving those particles with which it is in contact, and separating them from the rest of the water. And since the cause of solution in this case is the stronger attraction of the particles of water towards the air, than towards each other, those that are already dissolved and taken up, will be still further raised by the attraction of the dry air which lies over them, and thus will diffuse themselves, rising gradually higher and higher, and thereby leave the lowest air not so much saturated, but that it will be still able to dissolve and take up fresh particles of water. And thus ice or snow will evaporate as well as water, its particles being attracted and dissolved by the air, which is strongly pressed against its surface; for though heat promotes both solution and evaporation, yet we do not find that in either case any sensible degree of it absolutely necessary.

" In this manner will aqueous vapours ascend slowly into the atmosphere, even when we suppose the air almost at rest, for I believe it is never perfectly so. But the solution of water in air, and the ascent of vapours, is greatly promoted by the motion of the winds, which bring fresh and drier air into the place of that, which may be already saturated and loaded with moisture, carrying it, together with its moisture, into the higher parts of the atmosphere and dispersing it into all quarters.

" If we should now suppose the atmosphere to remain always of the same temperature as to heat and cold, and to have always the same density; when it was once saturated with water, all evaporation would cease, and the vapours already raised would always remain suspended; for a fluid, while it remains of the same temperature and density, will never let go the particles of a body that it has dissolved. We must therefore consider what are the causes which occasion the air sometimes to part with the water it has dissolved, and which thereby keep up a continual circulation of vapours; and these I shall shew to be the frequent vicissitudes of heat and cold, condensation and rarefaction, to which the atmosphere is subject.

" As to the effects of heat and cold, I have already shewn that the former promotes, and the latter checks or in some measure hinders evaporation as well as other solution; of which I gave an instance in the vapours that are suspended in the heat of the day, and by the cold of the night are precipitated and suffered to coalesce into drops of dew. From the snow that lies so long on the

the tops of mountains, and from the experience of those who have passed over them, we find that the higher parts of the atmosphere are much colder than the lower. Now though vapours are first raised, and abound most in the lower parts of the atmosphere, yet they cannot there form themselves into clouds, because the heat that helped to dissolve them, helps also to keep them dissolved. But when they are carried by the winds into the higher parts, where the same heat is wanting, the cold air will not be able to keep dissolved all that are carried up, but must suffer some of them to coalesce into small particles, which slightly attracting each other and being intermixed with air will form clouds, having the very same appearance with steam or smoke, which also consists of small particles of water mixed with air and not yet dissolved in it. These clouds when first formed will remain suspended, though they consist of water, as well as air; because the weight of their particles will not be able to overcome the resistance they must meet with in descending through the air. For when bodies are diminished, their quantities of matter, to which their weights are proportional, decrease faster, or in a greater ratio, than their surfaces to which the resistance they meet with is proportional, and therefore in very small particles, this resistance may become greater than their weight. The different heights at which clouds are formed, depends on the quantity of vapours carried up, and the degrees of heat in the upper parts of the atmosphere; for the vapours may always ascend 'till they meet with air so cold or so thin that it is not able to keep dissolved all that are carried up; hence clouds are generally higher in summer than in winter. When clouds are much increased by a continual addition of vapours, and their particles are driven close together by the force of the winds, they will run into drops heavy enough to fall down in rain. Sometimes the clouds are frozen before their particles are gathered into drops, and then small pieces of them, being condensed and made heavier by the cold, fall down in thin flakes of snow, which appear to be fragments of a frozen cloud; but if the particles be formed into drops, before they are frozen they become hail-stones.

“When the air is replete with vapours; and a cold breeze springs up, which it often does from the sea, the solution of these vapours is checked, and clouds are formed in the lower parts of the atmosphere, and compose what we call a mist or fog. This generally happens in a cold morning, but when the sun has been up for some time, the warm air again dissolves those watery particles, and it frequently clears up. In a hot summer's day the air lying over wet marshy ground is copiously filled with aqueous vapours, but the air growing cooler after sun-set, will not be able to keep all those vapours dissolved, but must let some part of them unite quickly into very small visible particles, and form those mists which appear to rise from marshy grounds in a summer's evening. The vapours near the ground being more dense and copious, will be first affected by the cold, and afterwards those that are thinner and higher up, so that the mist will be low at first, but will increase in height afterwards. But besides, these grounds and the water they contain will acquire such a heat from the sun that they may retain it for some time, and communicate it to the contiguous air, so that the vapours may continue to rise for sometime after sun-set, and will become visible when they get up a little way into the cooler air. After a warm and unclouded day in summer there falls abundance of dew, and the air scarce recovers its clearness 'till towards morning, when it is pretty much cooled; but on the first return of heat, at sun rise or a little before it, the water, which is then plentifully spread over the ground and the leaves of trees and plants in very small drops, begins again to dissolve, and while it is dissolving occasion that haziness so observable in a hot summer's morning about sun-rise and for some time after. Here it may be proper to observe, that when the particles of water are of a certain size, they will render the air equally opaque, whether they are passing into a state of solution, or returning from it.

“Those cold thick morning fogs I mentioned just now are often attended with a very light small rain; for

the vapours are then returning fast from a state of solution, and we see the drops at their first formation, and they are such as we generally meet with in passing over high mountains. So that it seems the drops of rain are very small when first formed in the clouds; but being driven about by the motion of the air in their descent, some of them will probably touch each other and run into a drop of a larger size, and the farther they have to fall, the more will their size be increased before they come to the ground. And for this reason, the drops which fall from the higher clouds in summer are found to be generally larger than they are in winter, when the clouds are low. It has been likewise observed that the drops of rain are remarkably large that fall in sudden thunder-showers; of which the reason may be, that the lightning bursting from a cloud and expanding itself greatly, will suddenly remove the air from its place, which air must therefore return to its place with great violence, and thereby the watery particles in the clouds will be strongly agitated and driven against each other, by which means they will form themselves into larger drops than at other times. Or perhaps it may be said, that when a cloud is filled with lightning, which is the same as the electric matter, the watery particles like other electrified bodies, will repel each other, but being suddenly deprived of this repelling matter, will by their mutual attraction come together again with some velocity, and therefore will run into drops larger than usual.

“When the wind blows from the south, it is generally warm and comes replete with aqueous vapours which it has dissolved, but coming into a colder climate it cannot there keep the same quantity of vapours dissolved that it did before, and consequently must part with some of them and let them precipitate; and therefore southerly winds generally bring us rain. On the other hand, when the wind blows from the north, or any point near it, as it is very cold it cannot have dissolved a great deal of aqueous vapours where it came from, and therefore coming into a warmer climate it is ready to dissolve more. And on this account these winds, if they continue long, are found to be very dry and parching, and are generally attended with fair weather.

“These seem to be the effects of heat and cold, as far as the different temperatures of the air will occasion it to dissolve and take up, or let go and precipitate the aqueous vapours, in consequence of which we sometimes perceive changes of the weather, even when there is no change in the height of the barometer.

“But condensation and rarefaction will also have the like effects in promoting the solution of water in air, or in occasioning some part of what has been dissolved to return again into water and precipitate. It seems reasonable to suppose, that dense air in which the particles lie very near each other, will be better able to dissolve and keep suspended a quantity of water, than the same air when diffused through a greater space. And that this is really so, we have an experimental proof. For when a receiver is partly exhausted, we see the rarefied air begin to let go the water it contained, which gathering into small particles appears like steam or smoke falling to the bottom. In order to prove the same thing by other experiments, when a cup of water or rather of spirit of wine (which evaporates faster) had stood for sometime in a close receiver full of air, I rarefied this air suddenly, by letting it rush into another receiver that was exhausted, and immediately the vapour that was before suspended gathered into small particles and fell down in a very visible shower. I also took from the air-pump a large exhausted receiver 20 inches long, having at the bottom a brass plate, with a stop-cock in the middle of it, when the stop-cock was opened, the external air rushing in violently, and being much rarefied, let go the water it contained, and threw it against the other end of the receiver, where it struck on the glass, and covered it with a thin dew, which I found to increase until the receiver was almost full of air.

“These experiments prove, that air when rarefied, cannot keep as much water dissolved as it does in a more condensed state. And hence we must conclude, that when the atmosphere is saturated with water, and changes from

from a denser to a rarer state, the higher and colder parts of it especially will begin to let go some of the water before dissolved; which will form new clouds or add to the size or number of the particles before formed, and thereby render them more apt to fall down in rain. On the contrary, when the atmosphere changes from a rarer to a denser state, it will then be able to stop the precipitation of the water and again dissolve in the whole, or in part, some of those clouds that were formed before, and consequently will render their particles less apt to run into drops and fall down in rain. And thus we generally find by experience, that the rarefied and condensed states of the atmosphere are respectively attended with rain or fair weather. Though this does not happen at all times, for the air, though rarefied, may not then abound much with aqueous vapours, having already parted with a good deal of them. So likewise when the air is dense and heavy it may then be much loaded with aqueous vapours, which will encrease its weight, (and indeed it must be so after a long continuance of fair weather) and we may then have rain even before we can perceive by the barometer, that the atmosphere changes to a rarer state.

“ Upon this principle, I think we may account for the changes of the weather, which usually, attend the rising and falling of the mercury in the barometer, better than by saying, that when the air grows rarer and lighter, it cannot by the laws of hydrostatics so well support the clouds and vapours, and therefore must permit them to fall down in drops of rain. For when the air grows rarer, although the clouds will descend into a lower and denser part of it, yet they will be there supported, and I do not see why their particles should be more apt to run into drops there, than when they were higher up, unless they receive some addition from the water deposited among them by the rarefied air, in the manner I have just now mentioned. For since the air is rarefied gradually, the clouds can descend but very slowly, and therefore their particles will not be so much pressed together by the resistance they meet with in their descent, as they generally are by the winds which blow upon them.

“ When the atmosphere is saturated with water, and grows colder and rarer than it was before, we shall then perceive the lower air begin to part with some of the water it contains, which will fall insensibly to the ground, or adhere to the walls of houses, or other bodies exposed to it, and make them become damp or wet. And if the moisture settles on the smooth surfaces of cold bodies, such as marble or other stones, whose pores cannot imbibe it, it will cover them with a kind of dew, and then those bodies are vulgarly said to sweat. At this time the hygrometer being affected by the moisture will point to wet, and as we perceive from thence, that the air is disposed to part with the water it contains, we may generally expect rain. But when the air again grows warm or dense, it will be able again to dissolve and take up the water it before deposited, and the moisture on the bodies exposed to it will disappear, the hygrometer will point to dry, and we may then promise ourselves fair weather.

“ I observed before that if a bottle be filled with a very cold liquor, and exposed to warm air, a dew will soon be formed on its surface, by the moisture which the cooled air deposits. Now if we suppose this body still to retain the same degree of cold whilst the air passes over it, the dew on its surface will continually encrease and run down its sides in small streams of water. This seems to be exactly the case of mountains whose tops reach into the colder parts of the atmosphere, and which therefore are themselves colder than the air in general. For when the wind blows the lower parts of the atmosphere, which are the warmest and most replete with vapours, against the sides of the mountains, it being there stopped in its course, must necessarily ascend and pass over their tops; this air will therefore be considerably cooled in its progress up the sides and over the tops of the mountains, and consequently must let go a great part of the watery vapours it contains; which will be precipitated in dew and moisture, upon the surface of the

mountains, where it will sink into the earthy parts, or insinuate itself into the chinks and crevices of rocks, and being there collected will afterwards break out in springs and fountains, and become the source of rivers, which are known to take their rise in mountainous countries. And on this account we might have small springs and rivers near mountains tho' there were neither clouds nor rain. But the moisture which the air usually deposits on the mountains must be considerably encreased by the clouds which are driven against them, and accumulated by the winds, for their particles being then pressed together will run into small drops of rain. Besides, it is well known that mountains gather and retain the clouds about them by their attraction, in consequence of which we often see some clouds continue at rest on the mountains, whilst the others are carried on gently by the wind. Hence it is that countries in the neighbourhood of high mountains are the most subject to frequent rains.

“ Thus I have shewn how the ascent of aqueous vapours and their constant circulation, by precipitating again in moisture and drops of rain, will arise from the dissolving power of the air, influenced by the vicissitudes of heat and cold, condensation and rarefaction; which causes, as they take place in different degrees, will occasion those various states of the atmosphere in respect to dryness or moisture which we experience in the several changes of the weather; to which the winds contribute very much by heating or cooling, condensing or rarefying the different parts of the atmosphere, and by promoting the solution of water in air, as they mix those fluids together, or, when the air is already saturated with aqueous vapours, by pressing together the particles in the clouds, and thereby causing them to run into drops.

“ If we may thus, from the known properties of solutions, account in a satisfactory manner for the ascent and circulation of aqueous vapours, and the several phenomena of the atmosphere arising from thence; it must be a greater confirmation of the arguments brought to prove that evaporation is only a particular species of solution; and therefore that they both proceed from the same cause, viz. the attraction that obtains between the minute particles of different bodies, which is the means of carrying on so many other operations of nature.

“ And indeed upon this principle, air seems better fitted to be a general solvent than any fluid we know of; because its particles, not attracting each other, are more at liberty to unite themselves to minute particles of such bodies as they do attract. And accordingly we find the atmosphere contains in it matter of all kinds. The odoriferous particles of bodies seem to be strongly attracted by the air, as they are so very readily dispersed through it; and camphor, which is a very light volatile body, may be entirely dissolved in air without leaving any remainder. The air abounds with vitriolic and other acids, as is plain from the rusting of iron exposed to it. It abounds also with sulphurous, nitrous, and other inflammable particles, as appears by the frequent meteors kindled in it. For we have many substances, such as strong acids and essential oils, which being thrown together will unite with such violence as suddenly to burst into a flame, and therefore when the particles of those bodies, floating promiscuously in the air, happen to come together in a sufficient quantity by their mutual attraction, which we know is very strong, they must kindle into a flame, and if many particles of the inflammable kind lie contiguous, the fire will run in a train and form, what we call, shooting stars, and other blazing meteors. In short, the atmosphere may be considered as a chaos containing particles of all sorts of bodies; and as the great instrument of nature for keeping up a general circulation of matter; and by which not only water is every where dispersed, but oftentimes the eggs of insects and the seeds of plants are conveyed from place to place, both which have been found in rain-water, on examining it carefully just after it had fallen; and indeed we sometimes find insects and plants in some places where their appearance cannot well be accounted

accounted for, otherwise than by supposing their eggs and seeds to be conveyed thither by the air.

"I shall now mention two other instances in which this dissolving power of the air produces effects of the utmost importance. Dr. Boerhaave, speaking of that power or quality of air, which makes it necessary for the preservation of animal life; calls it a certain hidden virtue, not to be accounted for from any of the properties of air then discovered. Perhaps we may be led to some knowledge of it, by considering on what account air may become unfit for respiration by passing two or three times through the lungs of an animal, for we find that an animal inclosed in such air will soon expire. I think we may be sure that one purpose, at least, for which air was designed is, the carrying off that moisture and other perspirable matter which constantly exhales from the lungs, for this we know it actually does. Now as air loses nothing of its elasticity by passing thro' the lungs, an animal might still continue to breathe the same air, and it would still continue fit for all such purposes in the animal oeconomy as may be answered by the alternate expansion and contraction of the lungs in respiration. But this air must in a short time become saturated with that moisture and other perspirable matter which it meets with in the lungs, and must then lose its power of dissolving and carrying off any more of that kind of matter; which nature intends should be constantly discharged, and which will therefore continually encrease, and thereby oppress the lungs, heat the blood, or produce such other noxious effects as are more immediately fatal than those arising from the stoppage of external perspiration. So that an animal inclosed in such air cannot live long, and will perhaps die somewhat in the same manner as if it had been drowned. Whether the air we breathe may deposite, in our lungs, any kind of matter necessary to the support of life, I cannot pretend to judge, nor is it my design to enquire; what has been said shews the necessity of fresh air in respiration, and by what property it is adapted to answer one very important purpose, and also how air may soon become unfit for that purpose. But here I will venture to ask, whether it is not probable, that, in the constant and quick evaporation of moisture from the lungs, some degree of cold may be produced, as in other evaporations, which, together with the fresh air taken in, may serve to cool the lungs, and the blood passing through them? We may see from hence that moist air must be very unwholesome by its not sufficiently promoting the necessary perspiration both internal and external.

"Air is not less necessary for the support of fire than of animal life; for fire will not long continue to burn without a circulation of air. Now I suppose this happens, not from its adding any thing to the pabulum of fire, for fire seems to be otherwise sufficiently provided with pabulum, but rather on this account; that the air immediately about a body on fire is heated and made specifically lighter than the air at some distance from it; this hot air must therefore ascend, and carry with it all those minute particles of different kinds which are thrown off from the burning body, and which would otherwise rest upon its surface, and thereby clog and stop the subtile vibrations of the burning matter, in which the nature of fire partly consists. If therefore fire be confined in a close place where there can be no circulation of fresh air, the air about it being soon saturated with the particles arising from the burning matter, will not be able to take up any more of them, and therefore the fire must go out, smothered as it were with such particles as are no longer combustible. And hence it is that fire burns faster when air is strongly blown upon it, for then the ashes are carried off as fast as they are formed on the surface of the burning body, and thereby the particles that have just taken fire are kept quite free from any thing that can impede and clog their vibratory motion. The air in this case will also spread the fire quickly through the fuel by blowing the particles that are already kindled among those that are not; and perhaps the motion of the air in this case may promote the subtile vibrations in the burning matter by which the fire is propagated through its parts.

"To this general observation, that air is necessary for the support of fire, we must admit one exception; for nitre will burn in a close vessel, or in vacuo. The cause of this singular phenomenon I shall endeavour to assign from what has been said. Nitre, when set on fire, burns with more rapidity and violence than any body we know of; its burning is a kind of explosion, and produces a very fierce and elastic flame; for which reason it is a necessary ingredient in gun powder, pulvis fulminans, and all other fulminating compounds. When therefore a piece of nitre takes fire, its elastic flame drives off the fumes and vapours, with which the air in the vessel may be then saturated, and defends the burning matter, so that they cannot settle upon it and extinguish it, as they do other bodies that burn slowly and without any explosion. And on this account nitre, and other inflammable matter mixed with it, will burn in close vessels or even in vacuo. This will further appear from considering the manner in which nitre first takes fire, and the reason of its exploding quality. Nitre will not burn by itself though melted and made red-hot; but when it comes in contact with any body actually on fire, and which therefore contains an inflammable matter, or, as it is called, the phlogiston, it bursts into a flame. Here the chymists say, that the acid spirit of the nitre unites so rapidly with the phlogiston, which is detached from the burning matter, that by the violence of their congress they both vanish together in a flame. And they prove this to be so, by throwing strong acid of nitre on any thick essential oil, which consists almost wholly of the phlogiston, for then the mixture will suddenly burst into a flame with a violent explosion. Therefore so long as nitre and the inflammable matter are thus in contact, no fumes or vapours floating about them can prevent that rapid union between their parts which must necessarily make them continue to burn. The air, which is produced from burning nitre, may possibly add to the elasticity of its flame. But I do not think it probable that this air can contribute much to keep a large quantity of nitre burning so long as it will do in a close vessel.

"Having thus shewn by what property air produces the evaporation of fluids and several other effects, I come now to treat of those vapours, that are raised merely by heat. Although the particles of fluids in common evaporation are raised into the atmosphere by the attracting and dissolving power of the air, yet in some particular cases vapours will rise into the air on another account. For in some places the earth often sends forth hot elastic vapours that rise into the air by means of their elasticity, and carry up with them mineral and fossil particles of different kinds. Fermentation generates elastic vapours, which expand themselves into the air. And the particles of water and other fluids, when sufficiently heated, acquire a repelling force which separates them from the surface, and throws them upwards into the air. But all these vapours soon lose that elasticity by which they were at first raised, and they must then be retained and kept suspended in the air by the same power that keeps up all the vapours that rise without any elasticity in common evaporation.

"That the particles of steam which rise from hot water are endued with a repelling force, appears plainly when water is boiled in a close vessel; for then the steam becomes so exceedingly elastic that, unless proper care be taken, it will burst the strongest vessel. In this case the boiling water, being strongly pressed by the force of the included steam, conceives a much greater heat than it will ever do in an open vessel; for even when water is boiled in the open air, it is somewhat hotter when the atmosphere is heavy, than when it is light, which shews that pressure upon boiling water encreases its heat; the reason of which we may perhaps see presently. But the most remarkable phenomenon that attends the boiling of water, is the large bubbles which continue to rise from the bottom so long as the water boils, and long after all the air is driven out of it, of the nature of which there have been various opinions. Doctor Boerhaave, in his Elements of Chymistry, proves by several arguments, that these bubbles do not arise from air, and with regard to their

their production, he seems to be of the same opinion with Stairs (to whose work he refers) that they arise from some active fires residing in the water. Mariotte, whom he also mentions on this occasion, calls these bubbles fulminations, and supposes that they may proceed from some kind of saline particles contained in the water, which, being heated, act in the same manner that the aurum fulminans does when melted. It has been also a received opinion that these bubbles are occasioned by some subtile elastic fluid transmitted from the fire thro' the bottom of the vessel. However, I conceive that a fluid so subtile as to pass thro' the bottom of the vessel, would pass also thro' the water so easily as not to disturb it; and therefore I have for some time suspected, that these bubbles are formed only by an elastic steam in the manner I shall now describe. The particles on the surface of the water, long before it boils, will, by means of the repelling force which the heat introduces among them, rise in steam, and will insinuate themselves into the air, which yields easily to them; but those particles that are pressed against the bottom, by the weight of the atmosphere, and of the incumbent water, will require a greater degree of heat to render them so elastic that they shall be able to overcome this pressure, and expand themselves into a greater space. Now since heat expands water, and makes its particles repel each other, according to its different degrees, we must suppose that these particles, from their being in contact with the bottom of the vessel, will at length acquire such a degree of heat as will give them a repelling force sufficient to overcome the pressure they sustain, and to expand them suddenly into those large bubbles that ascend through the water when it boils violently.

"I have lately made some observations and experiments which seem to confirm this opinion. These bubbles which ascend from the bottom, I observed, always grow less in their progress upwards; and those small bubbles, that adhere to the bottom for some time before they ascend, often disappear entirely before they reach the surface, which shews that when the matter they contain, or any part of it, loses the heat it had at first, it is again turned into water.

"When water that has just boiled, or is even considerably less hot than boiling water, is poured into a glass, and set under the receiver of an air-pump, and the air is almost drawn out, the water will boil more violently than it does on the fire, the bubbles breaking out from all parts of it. In this case, no subtile fluid can be supposed to rise through the bottom of the vessel, but the heat which the water retains will then give its particles an elastic force sufficient to overcome the pressure of what little air remains in the receiver, and will expand them into bubbles. And that these bubbles are composed of steam appears plainly from this experiment, for as soon as they begin to ascend, the receiver is filled with steam, which being condensed by the cold runs plentifully down its sides in water. From hence we may see the reason why water in vacuo boils with a very small degree of heat.

"After a vessel of water had boiled till all the air-bubbles were driven out of it, I turned upon its mouth a large glass that lay under the water; the bubbles, that ascended under the glass, remained in the upper part of it, and forced out the water it before contained, and then the elastic matter in the glass overturned it, and ascended to the top in one large bubble, upon which the steam on the surface was much increased. Now this shews that the matter contained in these bubbles, which at first is quite transparent, being a very rare and homogeneous fluid, appears afterwards like steam when it is mixed with the air. But I thought I should make a conclusive experiment, if I could observe the effects of a very hot steam conveyed under boiling water. Therefore when an æolipile had boiled till all the air was driven out of the water it contained, without taking it off the fire, I immersed its pipe into a vessel of water which had just been boiled, and immediately the steam, that issued from the pipe, rose up in very large bubbles thro' the water, and made it appear to boil violently. I then held a large glass of cold water, so that the pipe of the boiling æolipile was immersed in it; at first none of these

bubbles appeared, for the steam, being then condensed by the cold water, was mixed through it, making a very loud and uncommon noise: but as soon as the water in the glass grew very hot, this noise ceased, and the steam, being no longer condensed, rose in large bubbles, as before, and made the water appear to boil with great violence.

"These observations and experiments seem to discover fully to us the nature of those bubbles that ascend through boiling water; and lead me to make some further remarks on the degrees of heat that different liquors acquire in boiling.

"The parts of a fluid nearest the bottom of a vessel grow hot first, and being then expanded and made lighter, they ascend and change place with the colder and heavier parts, which occasions that intestine motion we perceive in liquors while they are growing hot. And thus the heat of the whole will continue to increase, until those particles, that are in contact with the bottom of the vessel, acquire such a degree of heat as will give them a repelling force sufficient to overcome the weight of the atmosphere, the weight of the incumbent fluid, and the tenacity of its particles; and then they will be suddenly expanded into bubbles of steam, and ascend quickly to the top, without communicating this heat to the surrounding fluid. For as these bubbles have a degree of heat but little superior to that of the fluid, and just sufficient to keep them expanded, if they were to lose any of it, by communicating it to the fluid in their ascent, they would all disappear before they got to the surface, as the very small ones do which ascend but slowly; or if the whole fluid was to grow at once as hot as the bubbles, it would, like them, be all turned into an elastic steam. And therefore the fluid itself cannot grow hotter than it was when these bubbles began to ascend; but must all boil away in the same degree of heat; provided it be such a fluid as will not grow denser, or more viscid and tenacious by boiling: of this kind are mercury, water, spirit of wine, and several others, for these fluids are found to boil respectively with 600, 212, and 175 degrees of heat, and afterwards they do not grow hotter. The reason of which is plain, for whilst the pressure upon a fluid, and its density and tenacity continue the same; the same degree of heat will always be sufficient to separate its particles, and expand them into steam; which is the greatest effect that fire can produce on any fluid without actually inflaming it. Hence it is obvious, that an additional pressure on boiling liquors, or an increase of their density or tenacity, will, by keeping their particles more strongly together, enable them to bear a greater degree of heat before they are expanded into steam and begin to boil. It is very observable that all oily liquors, which refract the rays of light more strongly than others do, acquire also a much greater heat in boiling. Thus oil of turpentine and other thin essential oils, that are procured by distillation, boil with about 560 degrees of heat, which however, as the boiling continues, is always increasing; the more volatile parts flying away, and leaving the residue thicker, more viscid, and susceptible of greater heat.

"Common vegetable and animal oils begin to boil with 600 degrees of heat, which is the same with that of boiling mercury, and therefore the greatest heat that can be measured by a mercurial thermometer. But it has been found, by the expansion of an iron rod, that oils grow continually hotter by boiling, and at length their heat increases so much that they burst into flame.

"There is indeed one observation, which, if true, would contradict what I have said as to the heat of boiling liquors being in some measure owing to their viscosity; for it is commonly said that tar, which is a viscid liquor, boils with so small a degree of heat, that the workmen skim the dross off it with their hands. But this I found to be only the appearance of boiling; for having placed a vessel of tar on the fire, as soon as the thermometer shewed it to be a little hotter than the human blood, a great quantity of air rose out of it in froth and bubbles, carrying up some dross with it, and then I could easily bear to hold my finger in it; but soon after, when the tar began really to boil, the thermometer rose as high as it does in boiling water, and was still

still rising. For tar, when one half of it is boiled away, becomes pitch; and it is well known that boiling pitch is hotter than boiling water; so that this experiment corresponds exactly with the theory I have laid down in regard to the heat of boiling liquors.

"Hitherto we have considered only the effects of such degrees of heat as are great enough to expand liquors into large bubbles and make them boil, or to raise a visible steam from their surface. But I find it necessary, for a reason I shall mention presently, to consider also the effects of the lesser degrees of heat, down to that which is just sufficient to keep liquors in a state of fluidity.

"It is generally allowed that heat keeps bodies fluid, by causing their particles in some measure to repel each other, and thereby preventing them from coming into such close contact as would render them hard. Now I shall shew from experiments that all degrees of heat above what is necessary to keep liquors fluid, will raise from their surface, provided they are not viscid, some kind of steam, which, for distinction's sake, I shall call an effluvium. Under a large glass set a cup of water, not hot enough to emit any visible steam, and let the glass be exposed to the cold air, a dew will soon appear on its inside. Here an effluvium is raised from the water, but it rises too slowly and in too small a quantity to become visible till it is condensed on the glass. As steam rises from hot liquors more abundantly when the pressure of the atmosphere is taken away, it may be supposed that this effluvium will also rise more copiously from colder liquors in the same case, as we shall see it really does by what follows. From a great number of experiments made with spirits of wine, of different degrees of strength, I found that, at a medium, the quantities lost in the same time in a close receiver full of air, in one only half full of air, in air rarefied two and forty times, and in the open air, were nearly in the proportion of 1, 14, 6, and 48. The same kind of spirit was used in each experiment, the time was 24 hours, and the spirits were contained in equal cups, so that their quantities and surfaces were as nearly equal as might be. That all the spirit used in each experiment might be in the same circumstances, before I put it into the cups I drew from it all the air I could by the air-pump, which could not rarefy the air in the receiver more than two and forty times: it was necessary to do this, because the spirit lost five or six grains in a few minutes while the air was drawing from it by the first exhaustion of the receiver, and a quantity less and less during the second and third exhaustions. A cup of water when in a warm room lost one grain on the first exhaustion, and when it had afterwards stood in the exhausted receiver for 24 hours it lost two grains and a half, while the same quantity of water lost 35 grains in the open air; but ice that was thawing, or water with ice in it, did not lose any thing in the exhausted receiver, or in a close receiver full of air. These experiments were made in a large room without a fire, and the fluids were of the same temperature, whose losses I compared together.

"The spirit of wine, which is so easily rarefied by heat, and which, as it never freezes, has always more heat than is sufficient to keep it fluid, lost in every experiment considerably more than water did in the same circumstances; and as water did not lose any of its weight, when it had not more heat than was necessary to keep it fluid, I think the rising of an effluvium from these liquors may justly be ascribed to the repelling force given to their particles by certain degrees of heat. The air in the receiver did not contribute to this effect, but on the contrary prevented it, in a great measure, by its pressure, for the more air was drawn from the receiver, the greater quantity of this effluvium arose. I observed, that when the air was rarefied two and forty times, the effluvium that rose from the spirit, which was sometimes near forty grains in twenty-four hours, not being supported by a sufficient quantity of air, and losing its first elasticity by being very much expanded, fell by its weight to the bottom, and covered it and the lower parts of the receiver with moisture. But none, or very little, of this moisture appeared when only one half of the air was drawn out of the receiver; for the effluvium which then

ascended, amounting generally to eight or nine grains, was supported by the remaining air; but when I rarefied this air suddenly, as in an experiment before mentioned, the effluvium was immediately gathered into a vast number of visible drops, and fell to the bottom. This plainly shews that the effluvia which are raised from liquors, by these very small degrees of heat, cannot continue suspended, unless they are supported by a sufficient quantity of air.

"I thought it necessary to make these experiments and observations, in order to obviate an objection which might be made to the principle I have endeavoured to establish. For as it is found that fluids lose of their weight both in an exhausted receiver, and in the open air, it might be said that this loss proceeded from the same cause in both cases, and therefore that common evaporation did not depend on the dissolving power of the air. But from these experiments, I think, we might give a sufficient answer to such an objection. For it appears first; that ice, or water, that has no more heat than is necessary to keep it fluid, lose nothing of their weight in an exhausted receiver, though they lose very considerably in the open air. Secondly, the quantity which the spirit of wine lost by evaporation in the open air was eight times greater than what it lost in the same time by an effluvium, when the air in the receiver was rarefied two and forty times; therefore the cause of evaporation must be a much more powerful one than that which raised the effluvium. And further, the quantity lost by evaporation was forty-eight times greater than what was lost, in the same time, by an effluvium, when the receiver was full of air; therefore, supposing the same effluvium to rise from it in the open air, we must allow that of the whole quantity which the spirit of wine lost in the open air, one part only in forty-eight could be owing to that effluvium which is occasioned merely by its heat, consequently forty-seven parts must have been carried off by some very powerful action of the air; which must also be the sole cause of the evaporation of ice or very cold water, which are found not to emit any effluvia in an exhausted receiver. And this action of the air I have shewn to be its dissolving power.

"Before we conclude, it may not be amiss to take a general view of the important purposes which air is contrived to answer, and of the means by which it is adapted to these several purposes. By its subtilty and elasticity it is capable of being easily taken into the lungs of animals; and by its attracting and dissolving power it carries on that perspiration, both internal and external, which we find is necessary to the preservation of life. By the same power it takes away the superfluous moisture from trees and plants, and thereby promotes vegetation. By the same power, it raises and sustains aqueous vapours, and its temperature and density being easily changed, it returns them again in rain and dew, and thus keeps up a continual circulation of moisture. By the same power it contributes to the support of fire, by carrying off from burning-bodies all such fumes and vapours as would otherwise extinguish them.

"By its weight and pressure on the surface of fluids it keeps their particles together, and enables them to bear, without being dispersed in steam, such degrees of heat as are necessary for all those uses to which boiling liquors are applied. By the same pressure it raises water in pumps and other hydraulic engines.

"And lastly; we may add to these, all the various purposes to which the winds are subservient; and which are too many to be enumerated, and too well known to require being particularly mentioned."

VAPORARIUM, a vapor-bath, in chemistry, implies a bath, or heat, wherein a body is placed so as to receive the fumes of boiling water.

VAPOUR. See the article **VAPOR**.

VAPOURS, in medicine, is the same with what is otherwise called the hypochondriacal disease. See the article **HYPOCHONDRIAC Passion**.

VARI, in medicine, are little hard and ruddy tumours, which frequently infest the faces of young persons of a hot temperament of body. The method of curing them is by giving cooling cathartics, and using a diluting

diluting diet. The cure however becomes more difficult in those which are of a lively red; for when the pustules are taken away the redness remains.

VARIABLE Quantities, in algebra and geometry, imply such quantities as are continually increasing or diminishing; in opposition to those which are constant, and remain always the same.

Thus the semi-ordinates, and abscisses of an ellipsis, &c. are variable quantities; because whenever the one increase, the other increases also. See the article **FLUXIONS**.

VARIABLE Winds. See the article **WIND**.

VARIANCE, in law, implies an alteration of something formerly laid in a plea: but where a plea is good in substance, it is held that a small variance will not injure it.

VARIANCE, also implies an alteration or change of condition in a person or thing; after some former concern, or transaction therewith.

VARIATION, in geography and navigation, is the deviation of the magnetical needle, from the true north-point of the horizon; or it is an arch of the horizon intercepted between the meridian of the place of observation, and the magnetic meridian. See the articles **COMPASS** and **MAGNET**.

The variation of the needle has within a century past undergone a remarkable alteration; for at London it was observed by Mr. Burrows, in the year 1580, to be $11^{\circ} 15'$ east; that is, if N. S. (plate CXXXIV. fig. 3.) represent the north and south points of the horizon, and E. W. the east and west points, the needle then had the situation A B, so that the arch $BN = 11^{\circ} 15'$. After that, in the year 1622, it was observed by Mr. Gunter to be but 6° east. In the year 1634, Mr. Gellibrand observed it to be $4^{\circ} 5'$ east. In 1657, it was observed by Mr. Bond to be nothing at all; that is, the needle placed itself in the situation S. N. and pointed directly to the north. After this, in the year 1672, Dr. Halley observed it to be $2^{\circ} 30'$ westward; and again, in the year 1692, he found it 6° west. Since then, in the year 1722, Mr. Graham, by most accurate experiments, found it to be $14^{\circ} 13'$; and at present it is between 15° and 16° ; and in some places it is found 18° westward.

The variation of the declination and inclination of the needle is variable, and subject to no regular computation. What the quantity of both sorts of variation is in the several parts of the world, is shewn in Dr. Halley's map of the world, improved from the observations of Mr. Pound.

If the sun's true amplitude or azimuth, found by calculation, agree with the magnetic amplitude or azimuth, found by observation, it is evident there is no variation; but if they disagree, and the true and observed amplitudes, at the rising or setting of the sun, be both of the same name; that is, either both north, or both south, their difference is the variation: whereas, if they be of different names, i. e. one north and the other south, their sum is the variation. Again, if the true and observed azimuths be both of the same name, i. e. both east or both west, their difference is the variation; but if they be of different names, their sum is the variation: and to know whether the variation be easterly or westerly, observe the following general rule; let the observer's face be turned towards the sun, then if the true amplitude or azimuth be to the right-hand, the variation is easterly; but if to the left, westerly. To illustrate this, let N E S W. (fig. 4.) represent a compass; and suppose the sun is really E b S at the time of observation, but the observer sees him off the east point of the compass, and so the true amplitude or azimuth of the sun is to the right of the magnetic, or observed: here it is evident, that the E b S point of the compass ought to lie where the east point is, and so the north where the N b W is; consequently the north point of the compass is too far east, i. e. the variation in this case is easterly. The same will hold when the amplitude or azimuth is taken on the west-side of the meridian.

Again, let the true amplitude or azimuth be to the left hand of the observed; thus suppose the sun is really E b N at the time of observation, but the observer sees

him off the east point of the compass, and so the true amplitude or azimuth to the left of the observed: here it is evident, that the E b N point of the compass ought to stand where the east point is, and so the north where the N b E point is; consequently, the north point of the compass lies a point too far westerly, so in this case the variation is west. The same will hold when the sun is observed on the west side of the meridian.

Suppose the sun's true amplitude at rising is found to be $E. 14^{\circ} 20' N.$ but by the compass it is found to be $E. 26^{\circ} 12' N.$ Required the variation, and which way it is.

Since they are both the same way, therefore,
from the magnetic amplitude — — — $E. 26^{\circ} 12' N.$
take the true amplitude — — — $E. 14^{\circ} 20' N.$

and there remains the variation — — — $11 52 E.$ which is easterly, because in this case the true amplitude is to the right of the observed.

VARIATION of the Moon, in astronomy, is the third inequality observed in that planet's motion. See the article **MOON**.

VARIATION of the Variation, is the change in the declination of the needle observed at different times in the same place.

VARIATION of Quantities, in algebra. See the article **COMBINATION**.

VARIATION of Curvature, in geometry, is used for that inequality or change which happens in the curvature of all curves, except the circle; and this variation or inequality constitutes the quality of the curvature of any line.

Sir Isaac Newton makes the index of the inequality or variation of curvature to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve; and Mr. Mac Laurin, to avoid the perplexity that different notions, connected with the same terms, occasion to learners, has adopted the same definition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it might have been proper to have measured the variation of curvature, rather by the ratio of the fluxion of curvature itself to the fluxion of the curve; so that the curvature being inversely as the radius of the curvature, and consequently its fluxion as the fluxion of the radius itself directly, and the square of the radius inversely, its variation would have been directly, as the measure of it, according to Sir Isaac's definition, and inversely as the square of the radius of curvature.

VARIATION, in music, is understood of the different manners of playing or singing a tune or song, whether by subdividing the notes into several others of lesser value, or by adding graces, &c. in such manner, however, as that one may still discern the ground of the tune through all the enrichments; which are called embroideries.

VARICIFORMES PARASTATÆ, in anatomy, a name which some authors give to two vessels near the bladder, by reason of their many turnings, serving to work and prepare the seed the better. See **DEFERENTIA VASA**.

VARIEGATION, among botanists and florists, the streaking and diversifying the leaves of plants, and the petals of flowers, with several colours.

Those leaves whose middles are variegated with yellow or white, in spots, are called bloached; as in several varieties of holly: but when the leaves are edged with either colour, they are called striped plants.

All the different sorts of variegation in plants were at first accidental, being no more than a distemper in the plant, which, being observed, has been cherished by impoverishing the soil in which they grow, by which method their stripes are rendered more lasting and beautiful; but whatever some persons have affirmed of stripping plants by art, there does not appear any foundation for such assertion, unless in woody shrubs and trees, which may be variegated by putting in a bud or graft taken from a variegated plant, where although the buds should not grow, yet if they keep fresh but a few days, they will often communicate their miasma to the sap of the tree into which they were budded; so that in a short time after, it has appeared very visible in the next adjoining

ing leaves, and has afterwards spread over the greatest part of the tree; but in such plants as are herbaceous, where this operation cannot be performed, there is no way yet ascertained whereby this striping can be effected by art.

That this striping proceeds from the weakness of the plant, is evident, since it is always observed, that whenever plants alter thus in the colour of their leaves, they do not grow so large as before, nor are they so capable of enduring cold; so that many sorts of plants, which are hardy enough to survive the cold of our climate in the open air, when in their natural verdure, require to be sheltered in the winter, after they are become variegated, and are seldom of so long continuance: which is a plain proof of its being a distemper in the plants, since, whenever they become vigorous, this striping is rendered less visible, or entirely disappears, especially if the plants are only bloached.

With some plants the venom of this morbid matter is such, that it not only tinges the leaves, but also the bark and fruit; as in the orange, pear, &c. whose bark and fruit are striped in the same manner as their leaves.

The different colours which appear in flowers proceed also from the same cause; for the various colours which we see in the same flowers, are occasioned by the separation of the nutritive juice of plants, or from the alteration in their parts, whereby the smaller corpuscles, which are carried to the surface of the flower-leaves, are of different forms, and consequently reflect different rays of light, whereby we obtain those various appearances of colour.

Among all the kinds of variegated flowers, none are more beautiful than the auricula, carnation, and tulip.

VARIOLÆ, the small-pox; See the article Pox.

VARIORUM, or *Cum Notis VARIORUM*, denotes an edition of a classic author, elucidated with the notes of various authors; and these editions are generally the most valued.

VARIX, in medicine, a dilation of a part of a vein so as to make it bulge out, and form a little, soft, knotty, but painless tumour.

Sometimes it is confined to one single branch of a vein; sometimes it extends to several; and sometimes it runs crooked, and bent in various knots and circumvolutions.

It most frequently happens to the crural and hæmorrhoidal veins; sometimes also to those of the testes, and often to those in the abdomen and breasts of pregnant women, and such as give suck. It is supposed to arise from the great abundance or thickness of the blood; or to the relaxation of the membranes of the veins; immoderate labour, sprains, cramps, to the great pressure or stricture by bandages. Stagnations of the blood from a plethora, &c. may also occasion varices.

Melancholy persons, and those who feed on coarse meats, are most subject to them: the generality of women with child have varices on their thighs and legs, occasioned by the foetus compressing the iliac veins; and by that means preventing the reflux of blood to the heart.

Varices happening spontaneously, and proving of a moderate size, are rarely dangerous; they are even allowed to be of service in the case of hæmorrhoids. When immoderate they sometimes occasion a cachexy, dropsy, or consumption.

The cure is to be attempted by evacuations, as phlebotomy, and cathartics: external applications, as discutient fomentations, cataplasms, embrocations, bandages, &c. and where the case becomes dangerous, by incision.

VARNISH, or VERNISH, a thick, viscid, shining liquor, used by painters, gilders, and various other artists, to give a gloss and lustre to their works; and at the same time to defend them from the weather, dust, &c.

There are several kinds of varnishes in use; as the drying varnish made of oil of turpentine, common turpentine and gum sandarach, melted together. White varnish made of oil of turpentine, fine turpentine, and mastic. Spirit varnish, the menstruum of which is spirit of wine,

in which are dissolved gum elemi, sandarach, mastic, white amber, &c.

1. To make the white varnish: take gum sandarach, of the clearest and whitish sort, eight ounces; gum mastic, of the clearest sort, half an ounce; of sarcocolla, the whitest, three quarters of an ounce; Venice turpentine, an ounce and a half; benzoin, the clearest, one quarter of an ounce; white rosin, one quarter of an ounce; gum animæ, three quarters of an ounce: let all these be dissolved, and mixed in the following manner.

Put the sarcocolla and rosin into a little more spirits than will cover them to dissolve; then add the benzoin, gum animæ, and Venice turpentine, into either a glass or glazed earthen vessel, and pour on as much spirits as will cover them an inch; then put the gum mastic into a glass or glazed vessel, and pour strong spirits upon it, covering it also about an inch thick, to dissolve it rightly; then put your gum elemi into a distinct vessel as before; and cover it with spirits to dissolve.

For this purpose, you need only break the rosin a little, and powder the gum animæ, sarcocolla, and benzoin.

Let all stand three or four days to dissolve, shaking the glasses, &c. two or three times a day, and afterwards put them all together into a glazed vessel, stirring them well, and strain the liquor and gums gently, beginning with the gums, through a linen cloth.

Then put it into a bottle, and let it stand a week before you use it, and pour off as much of the clear only, as you think sufficient for present use.

2. The white amber varnish is thus made according to Mr. Boyle: take white rosin, four drams, melt it over the fire in a clean glazed pipkin; then put into it two ounces of the whitest amber you can get, finely powdered.

This is to be put in by a little and a little, gradually, keeping it stirring all the while with a small stick, over a gentle fire, till it dissolves, pouring in now and then a little oil of turpentine, as you find it growing stiff; and continue so to do till all your amber is melted.

But great care must be taken not to set the house on fire, for the very vapours of the oil of turpentine will take fire by heat only; but if it should happen so to do, immediately put a flat board or wet blanket over the fiery pot, and by keeping the air from it, you will put it out, or suffocate it.

Therefore it will be best to melt the rosin in a glass of a cylindric figure, in a bed of hot sand, after the glass has been well annealed, or warmed by degrees in the sand, under which you must keep a gentle fire.

When the varnish has been thus made, pour it into a coarse linen bag, and press it between two hot boards of oak or flat plates of iron; after which it may be used with any colours in painting, and also for varnishing them over when painted.

But for covering gold, you must use the following varnish: mean time, it is to be observed, that when you have varnished with white varnish, you may put the things varnished into a declining oven, which will harden the varnish.

3. A hard varnish that will bear the muffle, may be thus made: take of colophony, an ounce; set it over the fire in a well-glazed earthen vessel, till it is melted; then by little and little, strew in two ounces of powder of amber, keeping it stirring all the while with a stick; and when you perceive it begin to harden or resist the stick, then put in a little turpentine oil, which will thin and soften it immediately; then put in two ounces of gum copal, finely powdered, sprinkling it in as you did the amber, now and then pouring in a little oil of turpentine; and when it is done, strain it as before directed.

This is proper to varnish over gold; and the things done with it must be set into a declining oven, three or four days successively, and then it will resist even the fire itself.

4. To make a varnish for brass, that will cause it to look like gold. Take two quarts of spirit of wine, and put it into a retort-glass; then add to it an ounce of gamboge, two ounces of lacca, and two ounces of mastic; set this in a sand-heat for six days, or else near a fire, or you may put the body of the bolt-head frequently into

warm water, and shake it two or three times a-day; then set it over a pan of warm saw-dust. But before this varnish is laid over the metal, let it be well cleaned.

This is a good varnish to mix with any colours that incline to red, and the amber-varnish for mixing with those that are pale.

5. To make a varnish for gold, or metals made in imitation of gold. Take colophony, and, having melted it, put in two ounces of amber finely powdered, and some spirit of turpentine, and, as the amber thickens, keep it well stirring; then put in an ounce of gum elemi, well pulverized, and more spirit of turpentine; constantly stirring the liquor till all is well mixed and incorporated: but take care, however, to use as little turpentine as you can, because, the thicker the varnish is made, the harder it will be. Let this be done over a sand-heat, in an open glass; then strain it, as is directed for the preceding varnish. This varnish is to be used alone, first warming the vessels made of paper-paste; and lay it on with a painting brush before the fire, but not too near, lest the fire raise it into blisters. After this has been done, harden it three several times in ovens; first with a slack heat, the next with a warmer, and the third with a very hot one; and the vessels will look like polished gold.

And as for such vessels, &c. as shall be made with saw-dust and gums, the varnish may be made of the same ingredients as above-mentioned, except the gum elemi; and this will dry in the sun, or in a gentle warmth.

6. To make a varnish for any thing covered with leaf silver. First paint the thing over with size, and ground chalk or whiting; let them stand till they are thoroughly dry, and then do them over with very good gold-size, of a bright colour (for there is much difference in the colour of it; some being yellow, and others almost white; the first is most proper for gold, and the last for silver.) When this size is so dry as that it will just stick a little to the touch, lay on the leaf-silver, and close it well to the size.

7. To make a varnish for silver. Melt, in a well glazed pipkin, some fine turpentine, and put in three ounces of white amber, finely powdered (more or less, according to the quantity your work will require) put it in by little and little, keeping it continually stirring, adding by degrees some spirit of turpentine, till all the amber is dissolved; and then add to it an ounce of sarcocolla well-beaten, and an ounce of gum elemi well levigated, adding now and then a little spirit of turpentine, till all is dissolved: do this over a gentle fire, and keep it constantly stirring.

This varnish will be as white and strong as the former; and is to be used warm, and hardened by degrees in an oven, as varnished gold, whereby it will look like polished silver.

Laying on of VARNISHES. 1. If you varnish wood, let your wood be very smooth, close-grained, free from grease, and rubbed with rushes.

2. Lay on your colours as smooth as possible; and, if the varnish has any blisters in it, take them off by a polish with rushes.

3. While you are varnishing keep your work warm, but not too hot.

4. In laying on your varnish begin in the middle, and stroke the brush to the outside; then to another extreme part, and so on till all be covered; for if you begin at the edges, the brush will leave blots there, and make the work unequal.

5. In fine works, use the finest tripoli in polishing: do not polish it at one time only, but, after the first time, let it dry for two or three days, and polish it again for the last time.

6. In the first polishing, you must use a good deal of tripoli, but in the next, a very little will serve: when you have done, wash off your tripoli with a sponge and water; dry the varnish with a dry linen rag; and clear the work, if a white ground, with oil and whiting; or, if black, with oil and lamp-black.

VARNISHING and preserving Pictures and Paintings. — The method of preserving paintings in oil is by coating them with some transparent and hard substance, as a var-

nish, to secure the colours from the injuries of the air or moisture; and to defend the surface from scratches or any damages the painting might receive from slight violences.

The substances, that have been, or may be used for this purpose, are gum arabic, glair or whites of eggs, isinglass size, and varnishes formed of gum resins dissolved in spirit of wine, or oil of turpentine; which last, where oil of turpentine is used, are called oil varnishes.

Gum arabic has been used, dissolved in water, as a varnish for pictures and paintings, on account of its being both more easily laid on, and taken off, than the varnishes formed of spirit of wine or oil of turpentine. It is more easily laid on, because it may be made exactly of that degree of viscosity with which it can be best worked with a brush or pencil; and because it is totally free from that accident called chilling, which attends all varnish made with spirit of wine. There is, however, along with these, another quality of so bad a kind, that its effects more than countervail these advantages in the use of gum arabic, as a varnish for paintings; which is, that as it dries, it is extremely apt to crack; and give such appearance of flaws and scratches, as obscure and deform the painting to an intolerable degree; and, therefore, this gum is at present much rejected with respect to this application; and the substance we shall next consider substituted in its place. The addition of sugar or sugar-candy will greatly prevent the cracking of gum arabic; but then it gives a viscosity or stickiness to the gum that makes the surface of the painting sully, and is in a manner equally detrimental with the cracking of the gum.

Glair of eggs, beat to an unctuous consistence, and spread with a proper brush over the paintings, answers much the same end as gum arabic: but has the like advantages with much less of the bad quality of cracking: for which reason it is generally preferred to that gum. It has, nevertheless, one great defect, which is its not lasting; for it requires to be renewed frequently, as either moisture or great dryness of the air injure it. It is usual to mix a little brandy or spirit of wine with the glair of the eggs, in order to make it work more freely with a brush; as also a lump of sugar to give it more body and prevent its cracking; from which, after all, it will not be intirely free, after it has some time laid on, if the picture be put into a very dry place.

Isinglass size may be used for a varnish in the same manner as the solution of gum arabic or the glair of eggs; and if a little honey or sugar, about a fourth or fifth of the weight of the isinglass, be added to it, it will cover more effectually than either of them, and yet be free from cracking. This is not, however, so lasting a varnish as the gum resins, especially if the painting or picture be brought into a damp situation; and indeed in all cases it is apt to turn very yellow with time: but where there is a prospect of having occasion to take off the varnish for altering the painting, this will be found a very good one; as it may be intirely removed by means of a sponge and hot water.

There have been many compositions invented for spirit and oil varnishes for paintings: but the multiplying a number of ingredients in such compositions is by no means attended with advantages that are equivalent to the trouble. We will, however, give one of the applauded recipes of each kind; and then subjoin to it another more simple, which we believe will better answer the purpose.

“Take of gum sandarac half a pound, of Venice turpentine one ounce and half, of the gums animi, and copal, each three quarters of an ounce, of mastic half an ounce, of benjamin, gum elemi, and white resin, each two drams, of rectified spirit of wine one pound. Powder the benjamin and gum animi; and put to them and the Venice turpentine, contained in a proper sized phial, eight ounces of the spirit of wine; to the copal and resin powdered, put, in like manner, in a phial, six ounces; and to the powdered gum elemi two ounces. Let them stand, shaking the phials frequently, till the gums, &c. be dissolved. Then strain all the solutions through a piece of fine linen into one bottle; and after

the mixture has stood some days, decant off as much as will separate clear; and keep it in a bottle well stopp'd for use.

Some omit the copal, which is in fact so much the same with the animi, that there is no certain mark of distinction known; and put in its place the same quantity of gum sarcocol: but it is not of any consequence, which is admitted; nor whether three parts in four of the ingredients be rejected: for the following will answer the end equally well.

“Take of the gums mastic and sandarac, powdered grossly, each six ounces, of Venice turpentine half an ounce, dissolve them in a quart of highly rectified spirit of wine, and strain off the solution as the above. If this be wanted harder, an equal weight of the gums animi or copal may be added, and the quantity of spirit of wine doubled.”

In the using this kind of varnish great care must be taken that the picture receive no damage from it: for the dissolving power of the spirit of wine will sometimes reach the oil of the painting, and consequently disturb the colours.

The varnish should, therefore, be spread with as little and as gentle work of the pencil as possible; and care should be taken, likewise, that the painting be thoroughly dry before the operation be attempted. There is also another nice circumstance to be attended to in the use of this kind of varnish, which is to avoid what is called the chilling of it; and will certainly happen, if the varnish be not laid on in a very warm place, or the picture itself warmed to a moderate degree: and this will be still more liable to happen, if the spirit of wine employed be not very highly rectified. If the varnish appear to be chilled, (that is, when the parts of the gums do not attract each other; but precipitate from the phlegm, left by the spirit on its evaporating away, in the form of a powder, which gives a misty turbid appearance to the surface, instead of a transparent shining one.) another coat should be laid over it, which will in general remedy the mischief; and indeed less than two or three coats of this kind of varnish is not sufficient to preserve the painting, and bring out the due effect of the colours; if they are in that state called sunk in, occasioned by the attraction of the cloth on the oils mixed with them.

The following is a recipe for an oil of turpentine varnish of the more compound kind.

“Take of the gums mastic and sandarac, each four ounces, of white resin two ounces, of the gums sarcocol, animi, copal, and olibanum, each one ounce. Powder them grossly; and put them into a phial with two pounds of oil of turpentine; stop the phial, but not too fast, lest it burst: and place it in any heat; the greater the better, under that which will make it boil. Let it stand there, till the gums be dissolved, or at least so much of them as will be dissolved, then strain off the solution for use.”

The ingredients, except the mastic and sandarac, may be omitted at discretion: and with respect to the gums animi and copal, under which names, a variety of gums brought from the East and West-Indies, as well as Africa, pass, there are a very few parcels which will be found to dissolve in oil of turpentine. Indeed we have never found any that would be so dissolved: but recipes like this have been given upon very good authority. The following, therefore, will be found a much cheaper, less troublesome, and equally good varnish with that made by this complex mixture.

“Take of gum sandarac two ounces, of mastic and olibanum each an ounce and half; or three ounces of mastic, and Venice turpentine half an ounce; powder them; and dissolve them in half a pound of oil of turpentine: proceeding as in the above.”

When this kind of varnish is used, it is particularly necessary that the painting should be thoroughly dry; and the pencil used as gently and sparingly in the laying it on as possible: for the oil of turpentine is extremely ready to dissolve the oil of the painting, if it be the least within its power: on which account the varnishes of this sort are much less used now than formerly. This

varnish, however, will spread much more easily than that with spirit of wine; and is not subject to chill, even though it be laid on without the aid of any warmth: but it is proper, nevertheless, to be very careful, that there be no damp or moisture on the surface of the painting; which would prevent the varnish from taking hold; and wholly frustrate the intention of it.

Varnishes have been used, likewise, formed of the gums sandarac, olibanum, and arabic, with white resin and turpentine, dissolved in linseed oil; but they are greatly out of use now, as such varnishes are slow in drying; and the linseed oil will turn yellow; besides the disadvantage arising from the impracticability of ever taking them off the painting again, whatever occasion there may be for it. But a very secure and good varnish may, nevertheless, be made, by dissolving two ounces of sandarac and olibanum, with half an ounce of Venice turpentine, in half a pound of old nut or poppy oil which is white; and if too fat for other use, the better.

All these varnishes must be carefully laid on with a pencil or brush, according to the circumstances before intimated to be proper for each kind: but with respect to those made of spirit of wine or oil of turpentine, particular care must be taken not to pass the pencil or brush more than once over the same place; for, otherwise, it will produce streaks and inequalities which spoil the effect.

Paintings in miniature are preserved by means of plates of glass, or the talc called isinglass, placed in the frame before them. There is no particular method to be observed in doing this: but to make the frame so compact, that the air may have no access; which, otherwise, will sometimes prey upon the colours.

Paintings in fresco, where they are of consequence enough to merit such care, may be rendered more durable, and preserved from foulness, by varnishing them with hot size boiled to a strong consistence, in which a fifteenth or twentieth part of honey has been dissolved.

Paintings in varnish require no means of preservation, but from violence; the varnish itself being a very sufficient defence of the colours against the air, moisture, or all other substances that might affect them.

VARNISH, also signifies a sort of shining coat, where, with potter's ware, Delft ware, China ware, &c. are covered, which gives them a smoothness and lustre. Melted lead is generally used for the first, and final for the second. See GLAZING.

VARNISH, among medallists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to counterfeit, enhances the value of them; that is, the colour which certain soils, in which they have a long time lain, tinges the metals withal: some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermilion colour; others with a certain shining polished brown, vastly finer than Brasil figures.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metals.

No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar, or lemon-juice.

Falsifiers of medals have a false or modern varnish, which they use on their counterfeits, to give them the appearance, or air, of being antique. But this may be discovered by its softness, it being softer than the natural varnish, which is as hard as the metal itself.

Some deposit their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal armoniac, and others burnt paper.

VAS, a vessel either for mechanical, chemical, culinary, or any other uses. In anatomy, all the parts which convey a fluid are called vessels, as the veins, arteries, and lymphatics.

VASA CONCORDIA, among hydraulic authors, are two vessels, so constructed as that one of them, though full of wine, will not run a drop; unless the other, be-

ing full of water, do run also. Their structure and apparatus may be seen in Wolfius Element. Mathes. t. I. Hydraul.

VASCULAR, VASCULARIS, in anatomy, is applied to any thing consisting of divers vessels, veins, arteries, &c. We say, the vascular and valvular texture of the lungs. All the flesh in an animal body, is found to be vascular, none of it parenchymous, as the ancients imagined.

VASCULAR, VASCULARIUS, in antiquity, was the denomination of a kind of artificers, among the ancient Romans; who made silver and gold vessels without relievo's or figures imbossed thereon.

Hence, according to Salmasius, it is, that Cicero, in his sixth oration against Verres, distinguished *vascularius* from *cælater*, engraver.

In the art called by the Greeks, *εμπαλίσκη*, which was the art of superadding ornaments of precious stones, or rich metals, to vases of other metals; the *vascularii* and *cælatores* were different; the first being the goldsmiths who made the vase, the second the sculptors who added the ornaments. But in the art called *τορευτική*, or the art of cutting bas reliefs, or stamping figures on metal; the *vascularii* were also *cælatores*, or engravers: that is, they who made the vase, made also the relieves or figures, wherewith it was enriched.

VASCULIFEROUS PLANTS, such whose seeds are contained in vessels, which are sometimes divided into cells.

VASE, a term frequently used for ancient vessels dug from under ground, or otherwise found, and preserved in the cabinets of the curious.

In architecture, the appellation vase is also given to those ornaments placed on corniches, soffles, or pedestals, representing the vessels of the ancients, particularly those used in sacrifice; as incense-pots, flower-pots, &c. They serve to crown or finish façades, or frontispieces; and hence called *acroteria*.

The term vase, however, is more particularly used in architecture, to signify the body of the Corinthian and Composite capital; otherwise called the tambour or drum, and sometimes the campana or bell. See **CORINTHIAN** and **COMPOSITE**.

Vase is sometimes also used, among florists, for what is more usually called the calyx, or cup.

VASSAL, in old law-books, a person who vowed fidelity and homage to a lord, on account of some land, &c. which he held of him, in fee.

VASTUS, in anatomy, the name of two of the extensor muscles of the legs; the one, called *vastus internus*, arises from the whole internal side of the femur; and the other, called *vastus externus*, takes its rise from the whole external side of the femur; and both together, with the *cruralis* and *rectus*, form a very robust and strong tendon just above the knee, to which the patella adheres behind, and which is inserted below the knee at a tubercle of the tibia.

VAT, or FAT, a vessel for holding wine, ale, beer, cyder, &c. in the time of their preparation.

VATICAN, a magnificent palace of the pope of Rome, which is said to consist of several thousand rooms: but the parts of it most admired are the grand stair-case, the pope's apartment, and especially the library, which is one of the richest in the world, both in printed books and manuscripts.

VAULT, Fornix, in architecture, an arched roof, so contrived that the stones which form it sustain each other.

Vaults are, on many occasions, to be preferred to soffits or flat ceilings, as they give a greater height and elevation, and are besides more firm and durable.

Salmasius observes, that the ancients had only three kinds of vaults. The first was the *fornix*, made cradle-wise; the second a *testudo*, i. e. tortoise-wise, which the French call *cul de four*, or oven-wise; and the third *concha*, or trumpet-wise.

But the moderns have subdivided these three sorts into many more, to which they have given different names, according to their figures and uses; some of them are circular, and others elliptical.

Again, the sweeps of some are larger, others less, portions of a sphere. All such as are above hemispheres,

are called high, or surmounted, vaults; and all that are less than hemispheres, are called low, or surbated, vaults, or testudines.

In some vaults the height is greater than the diameter; in others it is less: others, again, are quite flat, and only made with haunches; others like ovens, or in the form of a *cul de four*, &c. and others growing wider as they lengthen, like a trumpet.

There are also Gothic vaults, with ogives, &c. See **OGIVE**, &c.

Of vaults some again are single, others double, cross, diagonal, horizontal, ascending, descending, angular, oblique, pendent, &c.

Master VAULTS are those that cover the principal parts of buildings, in contradistinction to the upper or subordinate vaults, which only cover some little part, as a passage or gate, &c.

Double VAULT is one that is built over another, to make the outer decoration range with the inner; or, to make the beauty and decoration of the inside consistent with that of the outside, leaves a space between the concavity of the one and the convexity of the other. Instances of which we have in the dome of St. Peter's at Rome, St. Paul's at London, and in that of the Invalids at Paris.

VAULTS with Compartments, are such whose sweep, or inner face, is enriched with pannels of sculpture, separated by platbands. These compartments, which are of different figures, according to the vaults, and usually gilt on a white ground, are made with stone or brick-walls, as in the church of St. Peter at Rome, or with plaster on timber vaults.

Theory of VAULTS.—A semi-circular arch or vault, standing on two piers, or imposts, and all the stones that compose them, being cut, and placed in such manner, as that their joints or beds, being prolonged, do all meet in the center of the vault; it is evident, that all the stones must be in the form of wedges, i. e. must be wider and bigger at top, by virtue of which they sustain each other, and mutually oppose the effort of their weight, which determines them to fall.

The stone in the middle of the vaults, which stands perpendicular to the horizon, and is called the key of the vault, is sustained on each side by two contiguous stones, just as by two inclined planes; and, consequently, the effort it makes to fall is not equal to its weight.

But still that effort is the greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, i. e. if they were perpendicular to the horizon, as well as the key, it will tend to fall with its whole weight, and would actually fall, but for the mortar.

The second stone, which is on the right or left of the key-stone, is sustained by a third, which, by virtue of the figure of the vault, is necessarily more inclined to the second, than the second is to the first; and consequently the second, in the effort it makes to fall, employs a less part of its weight than the first. For the same reason, all the stones from the key-stone employ still a less and less part of their weight to the last; which resting on a horizontal plane, employs no part of its weight; or, which is the same thing, makes no effort at all, as being intirely supported by the impost.

Now, in vaults, a great point to be aimed at is, that all the voussoirs or stones make an equal effort towards falling. To effect this, it is visible, that as such (reckoning from the key to the impost) employ still a less and less part of its whole weight; the first, for instance, only employing one half, the second one third, the third one fourth, &c. there is no other way of making those different parts equal, but by a proportionable augmentation of the whole, i. e. the second stone must be heavier than the first, the third than the second, &c. to the last; which should be infinitely heavier.

M. de la Hire demonstrates what that proportion is, in which the weights of the stones of a semi-circular arch must be increased to be in æquilibrium, or to tend with equal forces to fall, which is the firmest disposition a vault can have.

The architects before him had no certain rule to conduct themselves by, but did all at random. Reckoning the

the degrees of the quadrant of a circle, from the key-stone to the impost, the extremity of each stone will take up so much the greater arch, as it is farther from the key.

M. de la Hire's rule is, to augment the weight of each stone above that of the key-stone, as much as the tangent of the arch of half the key. Now the tangent of the last stone of necessity becomes infinite, and of consequence its weight should be so too; but, as infinity has no place in practice, the rule amounts to this, that the last stones be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them; which is called the shoot or drift of the vault.

Mr. Parent has since determined the curve, or figure, which the extrados or outside of a vault, whose intrados, or inside, is spherical, must have, that all the stones may be in æquilibrium.

Key of a VAULT is a stone or brick in the middle of the vault, in form of a truncated cone, serving to bind or fasten all the rest.

Reins, or fillings up of a VAULT, are the sides which sustain it.

Pendentive of a VAULT, is the part suspended between the arches or ogives.

Impost of a VAULT is the stone whereon the first voussoir, or arch-stone of the vault, is laid.

UBIQUITARIANS, in church history, a sect of heretics, so called, because they maintained, that the body of Jesus Christ is *ubique*, every where, or in every place.

Brentius, one of the earliest reformers, is said to have first broached this error in Germany, about the year 1560. Melancthon immediately declared against it, as introducing a kind of confusion in the two natures of Jesus Christ. On the other hand, it was espoused by Flacius Illyricus, Osiander, and others. The universities of Leipzig and Wirtemberg in vain opposed this heresy, which gained ground daily. Six of their leaders, namely, Smidelin, Selnecker, Musculus, Chemnitius, Chytræus, and Cornerus, having a meeting, in 1577, in the monastery of Berg, composed a kind of creed, or formulary of faith, in which the ubiquity of Christ's body was the leading article. However, the Ubiquitarians were not quite agreed among themselves; some holding, that Jesus Christ, even during his mortal life, was every where; and others dating the ubiquity of his body from the time of his ascension only.

UBIQUITY, omnipresence, an attribute of the Deity, whereby he is always intimately present to all things; gives the esse to all things; knows, preserves, and does all in all things. See **GOD**.

For, since God cannot be said to exist in all places, as placed therein, because then he would need something to his existence, viz. place; and would have extension, parts, &c. he must be conceived to be every where, or in all things, as a first, universal, efficient cause, in all his effects.

He is present therefore to all his creatures, as a pure act or an exercise of an active virtue, which knows, preserves, governs, &c. every thing. Nor are even finite minds present, otherwise than by operation.

UDDER, *Uber*, in comparative anatomy, that part in brutes wherein the milk is prepared, answering to the mammæ, or breasts, in women.

VECTIS, the lever, one of the mechanical powers. See **LEVER**.

VECTOR, in astronomy, a line supposed to be drawn from any planet moving round a center, or the focus of an ellipsis, to that center or focus.

This, by some writers of the new astronomy, is called vector, or radius vector, because it is that line by which the planet seems to be carried round its center, and with which it describes areas proportional to the times.

VEDETTE, in the military art, a sentinel on horseback detached from the main body of the army, to discover and give notice of the enemy's designs.

VEER, a sea-term, variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run out of itself. It is not used for letting out any running rope except the sheet.

VEER is also used in reference to the wind; for, when it changes often, they say it veers about.

VEGETABLE, in physiology, a term applied to all plants, considered as capable of growth; that is, to all natural bodies which have parts organical formed for generation and accretion, but not sensation.

In vegetables, there is supposed to be a principle of life, commonly called the vegetative soul.

Boerhaave very scientifically defines a vegetable to be a body generated of the earth; to which it adheres, or is connected, by parts called roots, through which it receives the matter of its nourishment, and increase; and consisting of juices, and vessels, sensibly distinct from each other. Or, a vegetable is an organical body, composed of vessels and juices, every where distinguishable from each other; to which grow roots, or parts, whereby it adheres to some other body, from which it derives the matter of its life, and growth.

This definition furnishes a just and adequate idea of a vegetable: for by its consisting of vessels and juices, it is distinguished from a fossil; and by its adhering to another body, and deriving its nourishment therefrom, it is distinguished from an animal.

A vegetable is defined an organical body, because consisting of different parts, which jointly concur to the exercise of the same function.

Adhering by some of its parts to another body; for we know of no plant that is so absolutely vague and fluctuating, but has still a body it adheres to; though that body may be various, e. gr. earth, as in our common plants; stone, as in rock-plants; water, as in sea-plants; and air, as in some mucilages.

As to those few plants which appear to float with the water, their manner of growth is somewhat anomalous. M. Tournefort has affirmed that all plants do not arise strictly from solid seeds; but that some, instead of a solid semen, deposite, or let fall a little drop of juice, which sinking in the water, by its gravity reaches the bottom, or some rock, &c. in its way; to which it sticks, strikes root, and shoots into branches: such is the origin of coral.

Add, that the root of a plant may have any situation at pleasure, with respect to the body thereof; nor needs it either be lowest, or highest, &c.—Accordingly, in aloes, coral, mosses, fungus's, &c. the root is frequently uppermost, and the growth downwards.

The vascular structure of vegetables, is rendered very apparent, by an experiment of Mr. Willughby.—Cutting off some pretty big branches of birch, and making a sort of basin, or reservoir on the end thereof with soft wax; upon filling this with water, and holding the branch upright, the water, in a few minutes, sunk into the vessels of the wood, and running quite through the length, dropped out considerably fast at the other end; continuing so to do, as long as the water was poured on.—The same succeeds, in the sycamore, walnut-tree, &c. though the flux here is not so copious. *Philosophical Transactions*, N^o. 70.

There are secrets whereby the growth of vegetables is surprisingly promoted. Mr. Boyle mentions a virtuoso, who entertained his friends at the end of their meal with a sallad of lettuces, which he sowed in their presence, immediately before they sat down to table.

The chemists also furnish us with an extraordinary sort of what they call vegetables: as, the arbor Dianæ, arbor Martis, &c. In effect, gold, silver, iron, and copper, being prepared in aqua-fortis, there rises out of them a kind of tree, which vegetates, or grows, before the naked eye, and spreads into branches, leaves, &c. the whole height of the water; till all the matter is spent therein.

The water used by many in this process, the chemists call flint-water; the secret of which has been communicated by Rhodocanasses, a Greek chemist.

VEGETATION, the act whereby plants, and other living bodies, receive nourishment, and grow.

Plants, we learn from the microscope, consist of different parts, vessels, &c. analogous to those of animals: and each kind of vessel is supposed to be the vehicle of a different humour, or juice, secreted from the mass of

sap; which is considered as the blood, or common fund of them all.

Dr. Grew assigns the offices of the several vessels: those placed on the inner verge of the bark, he calls lymphæducts, and supposes them destined for the conveyance of the most aqueous, or watery liquor; these Mr. Bradley calls the new forming vessels, which are annually produced, and help to increase the bulk of the tree.

Those in the middle of the bark, Dr. Grew calls laciferous, or resiniferous vessels; their use, according to Bradley, is to return the superfluous sap; these vessels, Grew observes, are the principal viscera of plants; and adds, that as the viscera of animals are but such vessels conglomerated; so the vessels of a plant are viscera drawn out at length.

To the nutrition of plants, as well as that of animals, it seems necessary that there be a concurrence of two specifically distinct fluids; and a learned author maintains an intermixture of two such humours in every part of a tree, like that which we observe in linsey-woolsey: every part of sap being impregnated with other tinctures, and continually filtered from fibres of one kind to those of another. And from this mixture, many of the phenomena of the ripening, odours, colours, &c. are accounted for.

The process of nature, in the vegetation of plants, is very accurately delivered by the excellent Malpighi, to the effect following: the egg, or seed, of the plant being excluded out of the ovary, called pod, or husk, and requiring further fostering and brooding, is committed to the earth; which having received it into her fertile bosom, not only does the office of incubation, by her own warm vapours and exhalation, joined with the heat of the sun; but, by degrees, supplies what the seed requires for its further growth: as abounding every where with canals and sinuses, wherein the dew and rain water, impregnated with fertile salts, glide, like the chyle and blood in the arteries, &c. of animals. This moisture, meeting with a new deposited seed, is percolated, or strained through the pores or pipes of the outer rind, or husk, corresponding to the secundines of the fœtuses, on the inside whereof lies one or more, commonly two, thick seminal leaves, answering to the placenta in women, and the cotyledons in brutes.

These seed-leaves consist of a great number of little vesiculæ, or bladders, with a tube corresponding to the navel-string in animals. In these vesiculæ is received the moisture of the earth, strained through the rind of the seed; which makes a slight fermentation with the proper juice before contained therein. This fermented liquor is conveyed by the umbilical vessel to the trunk of the little plant; and to the gem, or bud, which is contiguous thereto: upon which a vegetation and increase of the parts succeed.

Such is the procedure in the vegetation of plants: which the illustrious author exemplifies in a grain of wheat, as follows: the first day the grain is sown it grows a little turgid; and the secundine, or husk, gapes a little in several places: and the body of the plant, being continued by the umbilical vessel to a conglobated leaf, which is called the pulp or flesh of the seed, and is what constitutes the flower, swells; by which means, not only the gem, or sprout, which is to be the future stem, opens, and waxes green: but the roots begin to bunch out; whence the placenta, or seed-leaf, becoming loose, gapes.

The second day the secundine, or husk, being broke through; the stem, or top of the future straw, appears on the outside thereof, and grows upwards by degrees: in the mean time, the seed-leaf guarding the roots, becomes turgid with its vesiculæ; and puts forth a white down. And the leaf being pulled away, you see the roots of the plant bare; the future buds, leaves, and rest of the stalk still lying hid. Between the roots and the ascending stem, the trunk of the plant is knit, by the navel-knot, to the flower-leaf; which is very moist, tho' it still retains its white colour, and its natural taste.

The third day, the pulp of the conglobated, or round leaf, becomes turgid with the juice which it has received from the earth, fermenting with its own.

Thus the plant increasing in bigness, and its bud or stem becoming taller, from whitish, it turns greenish: the lateral roots also break forth greenish, and pyramidal from the gaping sheath, which adheres closely to the plant; and the lower root grows longer, and hairy, with many fibres shooting out of the same.

Indeed there are hairy fibres hanging all along on all the roots, except on their tips; and these fibres are seen to wind about the saline particles of the soil, little lumps of earth, &c. like ivy; whence they grow curled. Above the lateral roots, there now also break out two other little ones.

The fourth day, the stem mounting upwards, makes a right angle with the seminal leaf: the last roots put forth more; and the other three, growing larger, are clothed with more hairs, which straightly embrace the lumps of earth; and where they meet with any vacuity, unite into a kind of net-work. The conglobate, or flower leaf, is now softer; and, when bruised, yields a white sweetish juice, like barley cream. By stripping it off, the root and stem of the plant are plainly seen, with the intermediate navel-knot, whose outer part is solid, like a bark, and the inner more soft, and medullary.

The fifth day, the stalk still rising, puts forth a permanent, or stable leaf, which is green, and folded; the roots grow longer, and there appears a new tumor of a future root: the outer, or sheath leaf is loosened; and the seed-leaf begins to fade.

The sixth day, the stable-leaf being loosened, the plant mounts upwards; the sheath-leaf still cleaving about it like a bark. The seed-leaf is now seen sinuous, or wrinkled, and faded: and this being cut or freed from the secundine, the flesh, or pericarpium, is found of a different texture; the outer part, whereby the outside of the seed or grain is heaved up, being more solid; but the inside vesicular, and filled with moisture, especially that part next the navel-knot. All the leaves being pulled off, the roots torn, and the flower-leaf removed, the trunk appears; wherein, not far from the roots, the navel-knot bunches out, and is solid, and hard to cut: above, there is the mark of the sheath-leaf, which was pulled off; and underneath, as in an angle, the gem is often hid. The hind part of the plant shews the breaking forth of the roots, and likewise the faded placenta, &c.

After the eleventh day, the seed-leaf, as yet sticking to the plant, crumpled, and almost corrupted; within it is hollow; and about the secundine, the mucous, and white substance of the seed, being continued to the navel-knot, forms a cavity. All the roots now becoming longer, put forth new branches out of their sides: the seed-leaf withers, and its vesicles are emptied: the internodes, or spaces between the knots, grow stronger; new gems appear, and the middle root grows several inches long.

After a month, the roots and stalk being grown much longer, new buds break out at the first knot, and little tumors bunch out, which, at length, break into roots.

The great attention of all who study botany, is at present placed on the discovery of new plants; but we are yet unacquainted with many peculiarities in the most common ones, which may prove not a less worthy employment for our thoughts.

The irregularities in the vegetation of the several parts of plants seems a subject well deserving our attention; and Mr. Marchand has laid before us an instance of this in one of our most vulgar plants, the common garden radish.

In the month of July, this gentleman observed a plant of this species, which had accidentally fixed itself in an open place, and was then full of flowers and pods. Towards the end of one of the branches, he observed a kind of tuberosity of an oblong shape, which looked somewhat like one of the pods of the plant, but that it was too long, and was very oddly twisted and contorted; this daily increased in size, and in a week was come to its full growth, which was, in the whole, about two inches and a half in length, and three quarters of an inch thick. It was of a very rough and knotty surface, and, like the rest of the stalk, had several pedicles of flowers growing on

on each side from it; it terminated in a smooth end, divided into three parts, which all turned upwards.

The longest of these points terminated in a green cartilaginous flower of the same substance with the protuberance which produced it; in this were all the regular parts of the flowers of the more perfect kind: there were four leaves which served for a cup; four more within these, which represented the petals; six other small bodies there stood in the middle of the flower, which represented the stamina; and among these another body which represented the pistil; so that here was, in this irregular vegetation, a representation at large of every part of the perfect flower of the radish, excepting only the apices; but these were all very different, in their nature and structure, from their similar parts in the natural flowers, being all of a hard, thick, and tough cartilaginous substance, and in colour of a greenish brown.

The shortest of the three points which terminated this tuberosity, had also at its end a resemblance of a flower composed of all the parts mentioned in the former, and of the same colour and substance with it, only differing in being a little smaller: and the third point had no regular resemblance of a flower, but was of the same cartilaginous substance, and of a semi-circular figure, and had its upper surface ornamented with several irregular protuberances. This irregular vegetation remained in vigour till October, when it gradually faded away, and there was no appearance of seeds in any part of it.

The radish, when its stalks are wounded by the pucerons, or other insects, will often throw out a protuberance of some irregular figure; but the resemblance of flowers in this, was a singularity never before observed.

To explain this, it will be necessary to observe, that every organised part of a plant contains in it a number of invisible seminal principles, capable of producing plants like that to which they have owed their origin; and this is a truth of which the succeeding instances will all bring very familiar and obvious proofs.

The graft of a tree, which, from only one single bud, produces a tree like that from which it was taken, certainly acts upon this principle; for the whole tree is quite different from the stock on which it is grafted, which serves for no other purpose but merely to convey to it a proper nutritive juice from the developing its parts.

We very well know, that there are many roots, which being cut into little slices of only a quarter of an inch thick, each of these will propagate its species, and send up new plants like that which the root belonged to; and, some roots being split longitudinally into four quarters, each of these will in the same manner grow and flourish, and shoot out roots from one part, and stalks from another, so as to furnish perfect plants the same year; and how can this be, but by their having been seminal points in all these pieces and sections of roots, which being dilated, and put in action by the humidity of the earth, have grown into perfect plants. Several of the bulbous-rooted plants produce off-sets from the several scales of their roots, and from the sides of their stalks; these in three years time produce perfect plants with their flowers; and what are these but so many seminal points ready upon occasion to be developed?

Nothing is so obvious, as that the slips or cuttings of trees, when planted in the ground, produce roots in one part, and buds for branches from another, and so finally become trees, like those from which they were cut; and this, though the piece that is planted, has no visible appearance of any bud in any part of it.

We also know, from daily experience, that many plants shoot out roots from their stalks as they grow, and that, though this usually happens in places where there is some solid substance for these new roots to fasten themselves to, yet it happens also in some plants where there is no such use for them; and what are these roots in a new part of a plant, but the effect of so many seminal points, ready to grow, both into roots and into branches, in all those places?

Among the thick and fleshy-leaved plants, as the opuntia, and other of the succulent plants of the Indies, there needs no more to produce a new plant, but to cut

off a part of a leaf, and stick it into the earth, where it will at once take root, and produce a new plant in a very short time. A thousand other instances of this kind might be given; but these may be sufficient to prove, that there are, in almost all parts of plants, certain seminal points, which, like the *plantula seminalis*, inclosed in the perfect seed of each, need only humidity, and a proper degree of warmth, to develop and unfold themselves into perfect plants.

We are not therefore to wonder at the imitation of perfection in any irregular productions of vegetables, since it appears that there are numbers of perfect plants contained in every part of a growing plant, of the same kind. *Mem. Acad. Par. 1709.*

As to the vegetable matter, or the food whereby plants grow, there is some doubt about it: the common opinion among naturalists, is, that water is the great vegetable food: which seems confirmed by an easy experiment.

A sprig of balm, mint, or the like plant, is set in a phial of pure water, without any mixture of earth; yet the sprig grows, and puts forth roots, leaves, and branches.

Agreeable to which, is another famed experiment of Van Helmont; who drying 200 pounds of earth, and planting a willow which weighed five pounds therein, watered it only with rain, or distilled water; and to secure it from any other earth, covered it with a perforated tin cover: at five years end, weighing the tree, with all the leaves it had borne in that time, he found it to weigh 169 pounds three ounces; yet the earth was only diminished two ounces.

To ascertain this point, Dr. Woodward has made some very good experiments; which, at the same time, give light to many other circumstances of vegetation. His experiments were most of them made with sprigs of mint, and some other plants, nicely weighed, and inclosed in equal glass phials, well covered up with parchment; leaving room for the stems to ascend through it; and filled with water: some with spring-water, others with rain water, others with Thames-water.

At the end of seventy-seven days he took them all out again; and weighed them, as also the water left; and computed the weight of water expended on them, and the proportion of the increase of the plant, to the expence of the water.

The next year, he made fresh experiments with the same phials, and the same sort of plants, weighed as before, only some were filled with another different water alone, others with the same water and a certain proportion of garden-earth dissolved in it; and others in the same water distilled.

At the end of fifty-six days, he weighed the plants, water, &c. and computed what each plant had gained, what quantity of water was expended on the plant, and the proportion of the increase of the plant, to the decrease of the water.

The result of all which experiments, he gives us in the following observations, and reflections. — 1. In plants of the same kind, the less they are in bulk, the smaller quantity of the fluid mass, in which they are set, is drawn off; the consumption, where the mass is of equal thickness, being pretty nearly proportional to the bulk of the plant.

In effect, the water seems to ascend up the vessels of plants, in much the same manner as up a filtre; and it is no great wonder, that the larger filtre should draw off more water than the smaller; or that a plant, that hath more and larger vessels should take up a greater share of the fluid, in which it is set, than one that has fewer: nor is this noted with regard to what follows.

2. Much the greater part of the fluid mass thus drawn off, and conveyed into the plants, does not settle or abide there; but passes through their pores, and exhales up into the atmosphere. — That the water, in these experiments, ascended only through the vessels of the plants, is certain; since some glasses, which had no plants in them, though disposed in like manner as the rest, remained at the end of the experiment as at first, without any diminution of water: and that the greatest part of it flies off from the plant, into the atmosphere, is as certain.

The last proportion of the water expended, was to the augment of the plant, as 46 or 50 to 1; and in some as 100, 200, nay, in one, as 700 to 1.

This so continual an emission of water, in so great plenty, from the parts of the plants, affords a manifest reason, why countries that abound with trees, and the larger vegetables especially, should be very obnoxious to damps, great humidity in the air, and more frequent rains, than others that are more open and free. The great moisture in the air, was a great inconvenience, and annoyance to those who first settled in America; which, at that time, was overgrown with woods and groves: but as these were burned and destroyed, to make way for habitations, and culture of the earth; the air mended, and changed into a temper much more serene and dry than before.

Nor does this humidity go off pure, and alone, but it usually carries with it many parts of the same nature, with those of which the plant, through which it passes, consists: the crasser, indeed, are not so easily borne up into the atmosphere, but are usually deposited on the surface of leaves, flowers, and other parts of the plants; whence our mannas, or honies, and other gummy exudations of vegetables: but the finer and lighter parts are with greater ease sent up into the atmosphere; thence they are conveyed to our organs of smell, by the air we draw in respiration; and are pleasant or offensive, beneficent or injurious to us, according to the nature of the plants from which they arise. And since these owe their rise to the water that ascends out of the earth, through the bodies of plants; we cannot be far to seek for the cause, why they are more numerous in the air in wet summers, and a greater quantity of odours is found exhaling from vegetables, in warm humid seasons, than in any others.

3. A great part of the terrestrial matter that is mixed with water, ascends up into the plant, as well as the water. There was much more terrestrial matter, at the end of the experiment, in the water of the glasses that had no plants in them, than in those which had plants. The garden mould dissolved in some of the glasses, was considerably diminished, and carried off; nay, the terrestrial and vegetable matter was borne up in the tubes filled with sand, cotton, &c. in that quantity, as to be evident, even to sense: and the bodies in the cavities of the other tubes, that had their lower ends immersed in water, wherein saffron, cochineal, &c. had been infused, were tinged with yellow, purple, &c. To look abroad a little towards our shores, and parts within the verge of the sea, these will present us with a large scene of plants, that, along with the vegetable, take up into them mermineral matter also, in great abundance; such is our sea-purslain, the several sorts of alga, of samphires, and other marine plants: these contain common sea-salt, which is the same as the fossil, in such plenty, as not only plainly to be distinguished on the palate, but it may be drawn out of them in considerable quantity; nay, some affirm, there are plants found that will yield nitre, and other mineral salts.

The vegetable matter being very fine and light, is surprisingly apt, and disposed to attend water in all its motions, and follow it into each of its recesses; as appears not only from the instances above alledged, but from many others; percolate it with all the care imaginable, filter it with never so many filtrations, yet some terrestrial matter will remain. Dr. Woodward has filtered water through several sheets of thick paper, and after that, through very close fine cloth, twelve times doubled; and this over and over, and yet a considerable quantity of this matter discovered itself in the water, after all. Now if it thus passes interstices, that are so very small and fine, along with the water, it is the less strange, that it should attend it in its passage through the ducts and vessels of plants: it is true, filtering and distilling the water, intercepts, and makes it quit some of the earthy matter it was before impregnated with; but then, that which continues with the water after this, is fine and light, and such, consequently, as is, in a peculiar manner, fit for the growth and nourishment of vegetables. And this is the case of rain water: the quantity of terrestrial matter it bears up into the atmo-

sphere, is not great; but what it does bear up, is chiefly of that light kind, or vegetable matter, and that too perfectly dissolved, and reduced to single corpuscles, all fit to enter the tubules, and vessels of plants: on which account it is, that this water is so very fertile and prolific.

The reason why all the terrestrial matter mixed with the water, does not ascend into the plant, is, that the mineral matter makes a great deal of it, which is not only gross and ponderous, but scabrous and inflexible; and so not disposed to enter the pores of the roots: besides, a great many of the simple vegetable particles, by degrees, unite, and form small clods, or molecules, which stick to the extremities of the roots of those plants; and others of them, entangled in a looser manner, form the nubeculae, or green bodies so commonly observed in stagnant water: these, when thus conjoined, are too big to enter the pores, or ascend up the vessels of plants; which singly they might have done.

Hence it is, that in agriculture, be the earth never so rich, good, and fit for the production of corn, or other vegetables; little will come of it, unless the parts of it be separated and loose: and it is on this account, such pains are bestowed in the digging, tilling, ploughing, fallowing, harrowing, and breaking the clodded lumps of earth: and it is the same way that sea-salt, nitre, and other salts, promote vegetation.

Some authors imagine nitre essential to plants; and that nothing in the vegetable kingdom is transacted without it: but Dr. Woodward assures us, that by all the trials he has been able to make, the thing seems to him quite otherwise: and that when contiguous to the plant, nitre rather destroys than nourishes it. But nitre, and other salts, certainly loosen the earth, and separate the concentered parts thereof; by that means fitting and disposing them to be assumed by the water, and carried up into the seed or plant, for its formation and increase. It is every person's observation, how apt all sorts of salts are to be wrought upon by moisture, how easily they run with it; and when these are drawn off, and have deserted the lumps wherewith they were incorporated, those must moulder immediately, and fall asunder of course: the hardest stone we meet with, if it happen, as it frequently doth, to have any sort of salt intermixed with the sand of which it consists, upon its being exposed to a humid air, in a short time dissolves and crumbles all to pieces; and much more will clodded earth, or clay, which is not of so compact and solid a constitution.

The same way is lime likewise serviceable in vegetation: the husbandmen say, it does not fatten, but only mellows the ground: by which they mean, it doth not contain any thing in itself, that is of the same nature with the vegetable mould, or afford any matter fit for the formation of plants, but merely softens, and relaxes the earth; by that means rendering it more capable of entering the seeds of vegetables set in it, in order to their nourishment, than otherwise it would have been. The properties of lime are well known, and how apt it is to be put in a ferment, and commotion by water; nor can such commotion ever happen, when lime is mixed with earth, however hard and clodded that may be, without opening and loosening.

4. The plant is more or less nourished, in proportion as the water in which it stands, contains a greater or smaller quantity of proper terrestrial matter in it. The truth of this proposition is discernible through the whole process of this author's experiments. The mint in one of his glasses, was of much the same bulk and weight with that of two or three others: but the water in which the first was, being river-water, which was apparently stored more copiously than the others with terrestrial matter, than the spring or rain-water, wherein the others stood, occasioned it to arrive at almost double the bulk that either of them had; and with a less expence of water too: so likewise the mint in another glass, in whose water was dissolved a small quantity of good garden-mould; though it had the disadvantage to be less, when first set, than either of the mints, in two other glasses, whose water was the very same with the first, only that it had none of the earth mixed with it; yet, in a short time, the plant not only overtook, but much out-stripped the others.

The

The reason why the proportion of the increase of the plant is limited to the quantity of proper terrestrial matter in the water, is, that all, even vegetable matter, is not proper for the nourishment of every plant: nor do there want good indications, that every kind of vegetable requires a peculiar and specific matter for its formation and nourishment; nay, each part of the same vegetable: and that there are very many and different ingredients to go to the composition of the same individual plant. If therefore, the soil wherein any vegetable or seed is planted, contains all, or most of these ingredients, and those in due quantity, it will grow and thrive there; otherwise it will not: if there be not as many sorts of corpuscles, as are requisite for the constitution of the main, and more essential parts of the plant, it will not prosper at all; if there are these, and not in sufficient plenty, it will never arrive to its natural stature; or if there be any the less necessary and essential corpuscles wanting, there will be some failure in the plant; and it will be defective in taste, smell, colour, or some other way.

Indeed, it is inconceivable how one uniform, homogeneous matter, having its principles, or original parts of the same substance, constitution, magnitude, figure, and gravity, should constitute bodies so unlike in all those respects, as vegetables of different kinds are; nay, even as the different parts of the same vegetable: that one should carry a resinous, another a milky, a third a yellow, a fourth a red juice in its veins; and one afford a fragrant, another an offensive smell; one be sweet to the taste, another acid, bitter, acerb, austere, &c. that one should be nourishing, another poisonous; one purging, another astringent. And this argument makes equally strong against those who suppose mere water the matter out of which all bodies are formed. A cataputia in one of the glasses received but little increase, only $3\frac{1}{2}$ grains all the while it stood, though 2501 grains of water were spent upon it: but this might possibly be owing, not to the water's wanting matter fit for the nourishment of that particular plant, but to the water's being an improper medium for it to grow in: too much of that liquor, in some plants, may probably hurry the terrestrial matter through the vessels too fast for them to lay hold of it.

But a farther proof of this doctrine is, that the soil once proper for the production of some sort of vegetable, does not always continue to be so; but, in a tract of time, loses its property; and this sooner in some lands, and later in others: if wheat, for example, be sown upon land proper for that grain, the first crop will succeed very well, and perhaps the second, and the third, as long as the ground is in heart, as the farmers call it; but in a few years it will produce no more, if sown with that corn; some other grain it may, as barley; and after this has been sown so often, that the land can bring forth no more of it, it may afterwards yield some good oats; and perhaps pease after them. At length it becomes barren; the vegetative matter that at first it abounded with, being reduced by the successive crops, and most of it borne off: each sort of grain takes forth that peculiar matter, that is proper for its own nourishment. It may be brought to bear another series of the same vegetables; but that not till it is supplied with a new fund of matter, of the like sort with what it first contained; either by the ground's lying fallow for some time, till the rain has poured a fresh stock upon it; or by the manuring it. That this supply is of the like sort, is evident from the several manures found best to promote the vegetation; which are, chiefly, either parts of vegetables, or of animals: of animals, we say, which either derive their own nourishment immediately from vegetable bodies, or from other animals that do so; in particular, the blood, urine, and excrements of animals; shavings of horn, and hoofs; hair, wool, feathers, calcined shells, lees of wine and beer, ashes of all sorts of vegetable bodies, leaves, straw, roots, and stubble, turned into earth by ploughing, or otherwise, to rot and dissolve there. These are our best manures; and being vegetable substances, when refunded back again into the earth, they serve for the formation of other like bodies.

The like is observable in gardens, where the trees, shrubs, and herbs, after their continuing in one station, till they have derived thence the greater part of the matter fit for their increase, will decay, and degenerate; unless either fresh earth, or some fit manure be applied to them: it is true they may maintain themselves there for some time, by sending forth roots farther and farther, to an extent all around, to fetch in more provision; but, at last, they must have a fresh supply brought to them, or they themselves must be removed or transplanted to some place better furnished with matter for their subsistence. And accordingly, gardeners observe, that plants that have stood a long while in a place, have longer roots than usual; part of which they cut off, when they transplant to a fresh soil, as not now of any farther use to them.

All these instances point forth a peculiar terrestrial matter, and not water, for the subject to which plants owe their increase: were it water only, there would be no need of manures, or transplanting; the rain falls in all places, in this field and that, indifferently; and on one side of an orchard or garden, as well as another: nor could there be any reason, why a tract of land should yield wheat one year, and not the next, since the rain showers down alike on each.

5. Vegetables then are not formed of water, but of a certain peculiar terrestrial matter. A little distillation shews, that there is a considerable quantity of this matter contained both in rain, spring, and river-water: and the experiments above-mentioned shew, that the much greatest part of the fluid mass that ascends up into plants, does not settle or abide there, but passes through the pores of them, and exhales into the atmosphere; and that a great part of the terrestrial matter, mixed with the water, passes up into the plant along with it; and that the plant is more or less augmented, in proportion as the water contains a greater or smaller quantity of that matter: from all which, we may reasonably infer, that earth, and not water, is the matter that constitutes vegetables.

One of the sprigs of mint drew up into it 2501 grains of the fluid mass, and yet had received but $3\frac{1}{2}$ grains of increase from it: a second, though it had at first the disadvantage to be much less than the third, yet, being set in water wherewith earth was plentifully mixed, and the other in water, without any such earth, it had vastly out-grown it; weighing, at least, 145 grains more than the former: a fourth plant, though at first a great deal less than the fifth, yet being set in the foul craft-water, that was first in the still, after that in which the last was set was drawn off, had gained in weight, at the end, above double what that in the finer and thinner water had. The proportion of the augment of that plant which thrived most, was to the fluid mass spent upon it, but as 1 to 46; in others, as 1 to 60, 100, 200; and in the cataputia, but as 1 to 714.—One of the sprigs took up 39 grains of water a day, one day with another; which was much more than the whole plant weighed originally, and yet it gained not $\frac{1}{4}$ of a grain a day in weight; and another took up 253 grains a day, which was near twice as much as its original weight; and after all, the daily increase of the plant was no more than $2\frac{1}{2}$ grains.

6. Spring and rain-water contain near an equal charge of vegetable matter; and river-water more than either of them. These proportions hold in the main, but a strict and just comparison is hardly to be expected, inasmuch as in all probability, the water that falls in rain, contains at some times a greater share of terrestrial matter, than that which falls at other times; a more powerful and intense heat, of necessity, hurrying up a larger quantity of that matter, along with the humid vapours that form rain, than one more feeble and remiss possibly can. The water of one spring may flow forth with a higher charge of this matter, than that of another: this depending partly upon the quickness of the ebullition of the water, and partly upon the quantity of that matter latent in the strata, through which the fluid passes, and the greater or less laxity of those strata: for the same reason the water of one river may abound with it, more

than that of another; nay, the same river, when much agitated, and in commotion, must tear up more of it, than when it moves with less rapidity, and violence. That there is a greater quantity of this matter in rivers, and that it contributes vastly to the ordinary fertility of the earth, we have an illustrious instance in the Nile, the Ganges, and other rivers, that yearly overflow the neighbouring plains; their banks producing the fairest and largest crops of any in the world.

7. Water serves only for a vehicle to the terrestrial matter which forms vegetables, and does not itself make any addition to them. Where the proper terrestrial matter is wanting, the plant is not augmented, though never so much water ascend into it: water, then, is not the matter that composes vegetable bodies; it is only the agent that conveys that matter to them, and distributes it to their several parts for their nourishment: that matter is sluggish and inactive, and would lie eternally confined to its beds of earth, without advancing up into plants; did not water, or some like instrument, fetch it forth, and carry it into them.

This fluid is capacitated for the office here assigned it, several ways: by the figure of its parts, which, as appears from many experiments, is exactly and mathematically spherical; their surfaces being perfectly polite, and without any the least irregularities. It is evident, corpuscles of such a figure are easily susceptible of motion, and far above any others whatever; and consequently are the most capable of moving and conveying other matter that is not so active: then, the intervals of bodies of that figure, are, with respect to their bulk, of all others, the largest, and so the most fitted to receive and entertain foreign matter in them; besides, as far as the trials hitherto made inform us, the constituent corpuscles of water are each, singly considered, absolutely solid, and do not yield to the greatest external force: this secures their figure against any alteration, and the intervals of the corpuscle, must, for this reason, be always alike. By the latter, it will be ever disposed to receive matter into it; and by the former, when once received, to bear it along with it. Water is farther capacitated to be a vehicle to this matter, by the tenuity and fineness of the corpuscles of which it consists: we hardly know any fluid in all nature, except fire, whose constituent parts are so exceeding subtile, and small, as those of water are: they will pass pores and interstices, that neither air, nor any other fluid will. This enables them to enter the finest tubes and vessels of plants, and to introduce the terrestrial matter, conveying it to all parts of them; whilst each, by means of organs it is endued with for the purpose, intercepts, and assumes into itself such particles, as are suitable to its own nature, letting the rest pass on through the common ducts.

8. Water is not capable of performing this office to plants, unless assisted by a due quantity of heat. This must concur, or vegetation will not succeed. The plants set in the glasses in October, and the following colder months, had not near the quantity of water sent up into them, or so great an additional increase by much, as those that were set in June, July, and the hotter months. It is plain, water has no power of moving itself, or rising to the vast height it does, in the more tall and lofty plants; so far from it, that it does not appear from any discovery yet made, that even its own fluidity consists in the intestine motion of its parts, whatever the Cartesians think. Indeed, we need nothing more to solve all the phenomena of fluidity, than such a figure, and disposition of parts, as water has: spherical corpuscles must stand so very ticklish upon each other, as to be susceptible of every impression; and though not perpetually in motion, they must be always ready and liable to be put into it, by any of the slightest force imaginable: it is true, the parts of fire, or heat, are not capable of moving themselves, any more than those of water; but they are more subtile, light, and active, than those are, and so are more easily put into motion.

That the concurrence of heat in this work is really necessary, appears not only from the experiments before us, but from all nature; from the fields and forests, gardens and orchards: we see in autumn, as the sun's power

is gradually less and less, so its effect on plants is remitted, and vegetation slackens by little and little. Its failure is first discernible in trees; which being raised highest above the earth, require a more intense heat, to elevate the water, charged with nourishment, to their tops; so that for want of fresh support and nutriment, they shed their leaves, unless secured by a firm and hard constitution indeed, as our ever-greens are: next the shrubs part with theirs; and then the herbs, and lower tribes; the heat being at length, not sufficient to supply even these, though so near the earth, and the fund of their nourishment. As the heat returns the succeeding spring, they all recruit again, and are furnished with fresh supplies and verdure: but first, those which are lowest and nearest the earth, and that require a lesser degree of heat to raise the water with its earthy charge into them; then the shrubs, and high vegetables, in their turns; and lastly, the trees. As the heat increases, it grows too powerful, and hurries the matter with too great rapidity, through the finer and more tender plants; these, therefore, go off, and decay; and others that are more hardy and vigorous, and require a greater degree of heat, succeed in their order. By which mechanism, provident nature furnishes us with a very various and differing entertainment; and what is best suited to each season all the year round.

As the heat of the several seasons affords us a different face of things, so the several distant climates shew the different scenes of nature, and productions of the earth. The hotter countries ordinarily yield the largest and tallest trees, and those too, in a much greater variety than the colder; even those plants common to both attain to a much greater bulk in the southern than the northern climes: nay, there are some regions so cold, that they raise no vegetables at all to any considerable size; this we learn from Greenland, Iceland, and other places of like cold situation and condition: in these there are no trees, and the shrubs are poor, little, and low. Again, in the warmer climates, and such as do furnish trees, and the large vegetables, if there happen a remission, or diminution of the usual heat, their productions are always impeded in proportion: our cold summers give us proof enough of this; for though, at such times, the heat we have is sufficient to raise the vegetative matter into the lower plants, our corns, wheat, barley, pease, and the like; and we have plenty of strawberries, raspberries, gooseberries, currants, and the fruits of such vegetables as are low and near the earth, and a moderate store of cherries, mulberries, plums, &c. and some others that grow at somewhat greater height; yet our apples, pears, walnuts, and the productions of the taller trees, have been fewer, and those not so thoroughly ripened, and brought to that perfection, as they are in more benign and warm seasons: and, indeed, in trees of the same kind, those that keep close to the earth, always produce the most and best fruit: for which reason it is, that the gardeners check and restrain the growth of their better fruit-trees, and prevent their running up to too great a height. As to our grapes, apricots, peaches, nectarines, and figs, they being transplanted hither out of hotter countries, it is the less wonder we have a failure of them in cold summers. Nor is it the sun, or the ordinary emission of the subterranean heat only, that promotes vegetation, but any other indifferently, according to its power and degree; as we find from our stoves, and hot-beds.

VEGETATIVE, *Vegetativus*, a term applied to that principle or part in plants, by virtue of which they receive nourishment, and grow or vegetate.

The philosophers speak of three kinds of souls, the vegetative, sensitive, and rational.

The vegetative soul is that principle whereby trees and plants live, grow, and produce their kind, &c.

This vegetative principle is differently seated in different plants: an ingenious author observes, that, generally speaking, its place is exactly between the trunk and root; at least, this appears to be the place in most of the semiferous tribe; which, if cut down near the place, rarely shoot again.

In other plants, as the elm, and many other edible plants, it seems to reside wholly in the roots; which, if

cut into ever so many parts, yet those being planted in the ground soon grow. In others, as in the willow kinds, it seems to be diffused all over, both root, trunk, and branches, insomuch that, if cut into a thousand pieces, there is no destroying them without splitting them in the middle, and scarcely then.

Lastly, in others, as the cereus's, ficus's, &c. it is seated in the body, branches, and leaves, any of which being put into the ground, strike root immediately, and grow.

The office of this vegetative principle is to concoct the indigested earth and salts which ascend through the roots, and to assimilate them to the nature of the plant.

VEHICLE, *Vehiculum*, in general, denotes any thing that carries or bears another along; but is more particularly used in pharmacy for any liquid serving to dilute some medicine, in order that it may be administered more commodiously to the patient.

VEIL, *Velum*, a piece of stuff serving to cover or hide any thing.

In the Romish churches, in time of Lent, they have veils or curtains over the altar, crucifix, images of saints, &c.

A veil or crape is wore on the head by nuns, as a badge of their profession: the novices wear white veils; but those who have made the vows, black ones.

VEIN, in anatomy, a vessel which conveys the blood from the artery back to the heart.

The veins are only a continuation of the extreme capillary arteries, reflected back again towards the heart, and uniting their channels, as they approach it, till at last they all form three large veins; the cava descendens, which brings the blood back from all the parts above the heart; the cava ascendens, which brings the blood from all parts below the heart; and the porta, which carries the blood to the liver. The coats of the veins are the same with those of the arteries, only the muscular coat is not as thin in all the veins, as it is in the capillary arteries; the pressure of the blood against the sides of the veins being less than that against the sides of the arteries. In the veins there is no pulse, because the blood is thrown into them with a continued stream, and because it moves from a narrow channel to a wider. The capillary veins unite with one another, as has been said of the capillary arteries. In all the veins which are perpendicular to the horizon, excepting those of the uterus and of the porta, there are small membranes or valves; sometimes there is only one, sometimes there are two, and sometimes three placed together, like so many half thimbles stuck to the sides of the veins, with their mouths towards the heart. In the motion of the blood towards the heart, they are pressed close to the sides of the veins; but, if the blood should fall back, it must fill the valves; and they being distended, stop up the channel, so that no blood can re-pass them.

The veins are best described by beginning with their trunks. The trunk of the cava descendens joins the trunk of the cava ascendens, and both together open into the right auricle of the heart. On the inside of the vein where the trunks join, there is a small protuberance which hinders the blood that comes from the upper parts, from falling upon that from the inferior parts, but diverts both into the auricle, where the cava descendens joins the auricle; it receives the coronary vein of the heart. As soon as it pierces the pericardium it receives the *αζυγος*, or vena sine pari; this vein runs along the right side of the vertebræ of the thorax, and is made by the union of the veins of the ribs on each side. Its small end at the diaphragma is divided into two branches, which communicate with a vein, sometimes from the emulgents, and sometimes from the cava ascendens. The cava descendens receives next the intercostalis superior, which is distributed in the interstices of the four first ribs to which the azygos comes. Remark, that the branches both of the one and the other run into the sinus's which are on the lower sides of the ribs. Sannichellius hath observed, that the trunk of the cava descendens receives a branch called pneumonica; it is this branch that accompanies the arteria bronchialis of M. Ruysch. The trunk of the cava descendens, as soon as it comes to the claviculæ, where it is sustained by the thymus, is divided into two

branches; the one goes to the right, and the other to the left; they are called subclaviæ, which receive several other branches: the first is the mammaria, which comes, sometimes, into the cava, before it divides into the subclaviæ; this vein is distributed in the breasts, and frequently goes lower, and makes an anastomosis with some branches of the epigastrica. The second is the mediastina, which is ordinarily one opening into the trunk of the cava; it goes to the mediastinum and thymus. The third is the cervicalis or vertebralis, which goes up the vertebræ of the neck, and casts some branches, by the bye, to the medulla spinalis. The fourth is the muscula inferior, which comes, sometimes, into the jugulars; it is distributed through the inferior muscles of the neck, and superior of the breast; the branch that answers this is called muscula posterior, because it is distributed in the muscles which are in the hind part of the neck. After that the rami subclavii are come out of the cavity of the breast, they are called axillares; they receive the scapularis internus and externus, which go to the muscles of the scapula, and to the glands in the arm-pits: then they are divided into two branches; the superior is called cephalica, and the inferior basilica. Into the basilica open the thoracica superior, which goes to the ducts and muscles of the breast; and the thoracica inferior, which spreads itself upon the sides of the breast, by several branches which communicate by anastomosis with the branches of the azygos under the muscles of the breast. The subclaviæ receive, also, the jugulares externi and interni, which go to the head. The jugulares externi ascend towards the ears, where they divide into two branches, the one internal, the other external. The internal goes to the muscles of the mouth, and of the os hyoides. The external, lying upon the parotides, divide into two branches, of which one is spread through all the face, and the branches on the one side unite with those on the other, and form the vena frontis; the other branch goes to the temples and hind-head. The jugulares interni ascend to the basis of the cranium, where they are divided into branches, of which the greatest open into the sinus lateralis of the dura mater, by the holes through which the eighth pair of nerves come out; the least go to the pia mater, by the hole which is nigh the cella turcica. The basilica and cephalica are the two principal veins of the arms and hands. The cephalica creeps along the arm between the skin and the muscles: it divides into two branches; the external branch goes down to the wrist, where it joins the basilica, and turns up to the back of the head, where it gives a branch, which makes the salvatella between the ring finger and the little finger. The ancients used to open this vein in diseases of the head, in continued and intermitting fevers; but the moderns approve not of this particular practice; since the knowledge of the circulation of the blood, there is no difference whether one be blooded in the cephalica, mediana, or basilica. The internal branch of the cephalica, together with a branch of the basilica, makes the mediana. The basilica, which is the inferior branch of the axillares, divides into three branches under the tendon of the musculus pectoralis. The first branch accompanies the fourth branch of nerves that goes to the arm. The second is called profundus; it reaches below the elbow, where it divides in two branches; the one external, which goes to the thumb, the fore-finger, and to the muscoli extensores carpi; the other internal, which goes to the middle finger, to the ring finger, to the little finger, and to the inner muscles of the hand. The third branch is called subcutaneus, towards the inner condyle of the arm; it divides into the ramus anterior and posterior: the first goes under the muscles of the ulna to the little finger, where it joins a branch of the cephalica; the second, near to the elbow, sends out a branch which goes to the wrist; then it unites with the cephalica interior, and forms the mediana. The mediana, which is made of the cephalica interior and the second branch of the ramus subcutaneus of the basilica, divides into two branches upon the radius; the one external, called cephalica pollicis, which runs between the thumb and fore-finger; the other internal, which goes between the ring and middle finger, and sometimes between this last and the fore finger. The trunk,

trunk of the cava ascendens, between the heart and diaphragma, does not lie upon the vertebræ, but runs at a small distance from them. At the diaphragma, it receives the phrenica or diaphragmatica. When it has pierced the diaphragmatica, it receives some large branches from the liver; then the cava ascendens accompanies the great artery from the liver to the fourth vertebræ of the loins, where it divides into two great branches, called iliaci; but before this division, it receives four branches from each side. The first is the vena adiposa, or renalis, which is spread on the coat and fat that covers the reins. The second is the vena emulgens, which goes to the kidneys, where it divides into several more branches. The third is the vena spermatica: the fourth is the vena lumbaris, which is not always one, but often two or three on each side, which they divide into superior and inferior; they are bestowed on the muscles of the loins, and on the peritonæum. They sometimes call the last branch of the lumbaris muscula superior.

There are some anatomists who have observed a branch of the lumbaris which enters the cavity of the vertebræ, and ascends to the brain; which gave them occasion to think, against all probability, that the seed descended, by that vein, from the brain. A little below the emulgents, the great artery goes above the cava; and then the cava divides into two branches called iliaca, because they pass above the ilia to go to the thighs. Near this division, they receive one or two branches, called venæ sacrae; they go to the medulla of the os sacrum. Then the vena iliaca divides into two branches, the one internal, the other external. The internal receives two branches, the muscula media, which is spread thro' the muscles of the thigh; the hypogastrica, which is sometimes double, and spread about the sphincter of the anus; therefore, it is called the hæmorrhoidalis externa. The hypogastrica is spread, also, upon the body of the bladder, upon the matrix, and its neck. The external branch of the iliaca receives three branches, two before it goes out of the peritonæum, and the third after it goes out of it. The first is the vena epigastrica, which comes rarely into the cruralis; it goes to the peritonæum, ascends to the muscoli recti, where it rencounters the mammariæ, with which it communicates by anastomosis. The second is the vena pudenda; it is spread upon the parts of generation. The third is the muscula inferior; it goes towards the articulation of the femur, and is distributed to the muscles of this part. The iliaca exterior, after it has received all these branches, takes the name cruralis, and then receives six branches more. The first is the vena saphæna, which goes down under the skin along the inside of the thigh and leg, accompanied by a nerve which loses itself at the inner ankle. The saphæna turns towards the upper part of the foot, where it gives several branches, of which some go to the great toe. The second is the ischias minor; this vein is little; it is spent on the muscles and skin, which are about the upper joint of the femur. The third is the muscula externa, because it goes to the external muscles of the thigh. The fourth is the poplitæa, made of two different branches united together; it goes straight down by the ham to the heel; it lies pretty deep, upon which account it can hardly be opened. The branches which appear, in this place, are not of this vein. The fifth is the furalis, which is pretty big, and divides in two branches, the one external, which is least; the other internal, which is biggest. Each of these divide again into two more; the one external, the other internal. The furalis distributes its branches upon the fat of the leg, and makes, with the branches of the poplitæa, all those plexus's of veins which are conspicuous on the upper part of the foot. The sixth and last branch of the cruralis is the ischias major, which goes, also, to the muscles and fat of the leg, and is divided, afterwards, into several branches. In order to give a better idea of the several veins of the human body, we have given a draught of them, where *a, a,* (plate CXXXV. fig. 1.) represents the orifice of the cava cut from the right auricle; *b, b,* the descending trunk of the cava; *c, c,* ascending trunk; *d, d,* subclavian veins; *e, e,* vena azygos; *f, f,* intercostal veins; *g, g,* mammary veins; *i, i,* internal ju-

gulars cut off at the basis of the scull *k, k*; *l, l,* external jugulars; *m,* right axillary vein; *n,* cephalic vein; *o,* basilic; *p,* mediana.

Fig. 2. *a,* the bulbous trunk of the vein; *b,* its orifice tied up when cut from the left ventricle of the heart; *c,* left ventricle of the heart; *d, d, d,* &c. branches and ramifications.

Fig. 3. *a,* represents the trunk of the cava; *b,* part of the diaphragm.

Fig. 4. *a,* represents the trunk of the pulmonary artery, in the time of expiration, cut close to the basis of the heart; *b, b,* its divisions to the right and left lobes of the lungs; *c,* the canalis arteriosus; *d, d,* &c. the extremities of the arteries freed from the vesicles of the lungs, and their inosculation with the pulmonary veins.

Fig. 5. *a,* represents the place where the porta enters the liver; *c,* the umbilical vein turned to a ligament; *d,* the canalis venosus also, become a ligament; *e, e,* &c. the extremes of the capillary veins.

VEIN, among miners, is that space which is bounded with woughs, and contains ore, spar, canck, clay, chirt, croil, brown-hen, pitcher-chirt, cur, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

The veins of mines differ greatly from one another in depth, length, and breadth; some stretch obliquely, from the surface toward the central parts of the earth; and these the miners call deep veins; others lie shallow and circular, so as to encompass a large space, and these are termed spreading veins: others possess a great part of the space they lie in, both in length and breadth, and these are called accumulated veins, being no more than a space possessed by a large group of fossils of one kind. To give the complete history of veins and fibres, which are smaller veins, their differences, their directions, their interstices, their discontinuations, their risings and fallings, and their goodness, would be a large work. Let it be observed, however, that these things seem all to proceed in a certain order, though that order, and the laws and rules of it, are not perfectly understood, so as to afford sure directions for practice; whence it sometimes happens, that, after a vein has been successfully traced for some time, it dips, breaks off, or takes a different course, leaving the workmen as it were at a fault.

When the vein is found, a pit is to be sunk upon it, and a crane fixed at the top of the pit for craning up the ore. Burrows, or adits, are also to be cut horizontally through the hill in one or more places, reaching to the mine, and serving to wheel out the ore, instead of craning it up.

VELAMENTUM BOMBYCINUM, a name which some anatomists give to the velvet membrane, or inner-skin of the intestines.

VELARIUS, in antiquity, an officer in the court of the Roman emperors, being a kind of usher, whose post was behind the curtain in the prince's apartments; as that of the chancellors was at the entry of the balustrade, and that of the ostiarii at the door. The velarii had a superior of the same denomination who commanded them.

VELITES, in the Roman army, a kind of antient soldiery, who were armed lightly with a javelin, a cask, cuirasse and shield.

VELLEITY, *Velleitas*, in the school-philosophy, is usually defined a languid, cold, and remiss will. Others say, it implies an impotency of obtaining what we require. Others will have it a slight desire for something which a person does not matter much, or is too indolent to seek.

VELLICATION, among physicians, the act of twitching. The word is more particularly applied to a sort of sudden convulsions that happen to the fibres of the muscles.

VELOCITY, Swiftness, or that affection of motion whereby a moving body is disposed to run over a certain space in a certain time. See MOTION.

For the velocity of falling bodies, see the article ACCELERATION.

In the doctrine of fluxions it is usual to consider the velocity with which magnitudes flow, or are generated. Thus, the velocity with which a line flows, is the same as that of the point, which is supposed to describe or generate the line. The velocity with which a surface flows, is the same as the velocity of a given right line, that, by moving parallel to itself, is supposed to generate a rectangle, always equal to the surface. The velocity with which a solid flows, may be measured by the velocity of a given plain surface that, by moving parallel to itself, is supposed to generate an erect prism, or cylinder, always equal to the solid. The velocity with which an angle flows, is measured by the velocity of a point, supposed to describe the arc of a given circle, which subtends the angle, and measures it. All these velocities are measured at any term of the time of the motion, by the spaces which would be described in a given time, by these points, lines, or surfaces, with their motions continued uniformly from that term.

The velocity with which a quantity flows, at any term of the time, while it is supposed to be generated, is called its fluxion.

VELOM, a kind of parchment, finer, evener, and whiter than the common sort. See PARCHMENT.

VELVET, a rich kind of stuff, all silk, covered on the outside with a close, short, fine, soft shag, the other side being a very strong close tissue.

The nap or shag, called also the velveting, of this stuff, is formed of part of the threads of the warp, which the workman puts on a long narrow-channeled ruler or needle, which he afterwards cuts, by drawing a sharp steel tool along the channel of the needle to the ends of the warp. The principal and best manufactories of velvet are in France and Italy, particularly in Venice, Milan, Florence, Genoa, and Lucca: there are others in Holland, set up by the French refugees; whereof that at Harlem is the most considerable: but they all come short of the beauty of those in France, and, accordingly, are sold for 10 or 15 per cent. less. There are even some brought from China, but they are the worst of all.

There are velvets of various kinds; as plain, that is, uniform and smooth, without either figures or stripes.

Figured velvet, that is, adorned and worked with divers figures, though the ground be the same with the figures; that is, the whole surface velveted.

Ramage or branched velvet, representing long stalks, branches, &c. on a fatten ground, which is sometimes of the same colour with the velvet, but more usually of a different one. Sometimes, instead of fatten, they make the ground of gold and silver; whence the denominations of velvets with gold ground, &c.

Shorn velvet, is that wherein the threads, that make the velveting, have been ranged in the channeled ruler, but not cut there.

Striped velvet, is that wherein there are stripes of divers colours running along the warp, whether these stripes be partly velvet, and partly fatten, or all velveted.

Cut velvet, is that whereon the ground is a kind of taffety, or gros de tours, and the figures velvet.

Velvets are likewise distinguished, with regard to their different degrees of strength and goodness, into velvets of four threads, three threads, two threads, and a thread and a half: the first are those where there are eight threads of shag, or velveting, to each tooth of the reed; and the second have only six, and the rest four.

In general, all velvets, both worked and cut, shorn and flowered, are to have their warp and shag of organism, spun and twisted, or thrown in the mill; and their woof of silk well boiled, &c. They are all of the same breadth.

Colour of black VELVET. The manner of giving this deep and fine colour to glass is this: take of crystalline and pulverine frit, of each twenty pounds; of calx of lead and tin four pounds: set all together in a pot in the furnace, well heated. When the glass is formed and pure, take steel well calcined and powdered, scales of iron that fly off from the smith's anvil, of each an equal quantity; powder and mix them well; then put six ounces of this powder to the above described metal while in fusion; mix the whole thoroughly together, and let all boil strongly together; then let it stand in fusion twelve

hours to purify, and after this work it. It will be a most elegant black. There is another way of doing this, which also produces a very fair black. It is this: take an hundred weight of rochetta frit; add to this two pounds of tartar, and six pounds of manganese, both in fine powder; mix them well, and put them to the metal while in fusion, at different times, in several parcels; let it stand in fusion after this for four days, and then work it. *Neri's Art of Glass.*

VENAL, or VENOUS, among anatomists, &c. something that bears a relation to the veins.

This word is also used for something bought with money, or procured by bribes.

VENEERING, VANÉERING, or FINEERING, a kind of marquetry, or inlaying, whereby several thin slices or leaves of fine woods, of different kinds, are applied and fastened on a ground of some common wood.

There are two kinds of inlaying: the one, which is the most common and more ordinary, goes no farther than the making of compartments of different woods; the other requires much more art, in representing flowers, birds, and the like figures.

The first kind is properly called veneering; the latter is more properly called marquetry.

The wood used in veneering is first sawed out into slices or leaves about a line in thickness; i. e. the twelfth part of an inch. In order to saw them, the blocks or planks are placed upright, in a kind of sawing press. See SAWING-MILL.

These slices are afterwards cut into narrow slips, and fashioned divers ways, according to the design proposed; then the joints having been exactly and nicely adjusted, and the pieces brought down to their proper thickness, with several planes for the purpose, they are glued down on a ground or block, with good strong English glue.

The pieces being thus jointed and glued, the work, if small, is put in a press; if large, 'tis laid on a bench covered with a board, and pressed down with poles or pieces of wood, one end of which reaches to the ceiling of the room, and the other bears on the board.

When the glue is thoroughly dry, it is taken out of the press and finished; first with little planes, then with divers scrapers, some of which resemble rasps, which take off the dents, &c. left by the planes.

After it has been sufficiently scraped, they polish it with the skin of a sea-dog, wax and a brush, or polisher of shave-grass; which is the last operation.

VENEREAL, something belonging to venery; as the lues venerea, French disease, or pox. See POX, GONORRHOEA, &c.

VENERIS OESTRUM, the stimulus or incentive of venery, is an appellation given by some anatomists to the clitoris.

VENERIS OESTRUM is also used by others for the transport of love, or the utmost extacy of desire, or enjoyment, in coition.

VENERY is used for the act of copulation, or coition, of the two sexes. See the article GENERATION.

VENERY also denotes the act or exercise of hunting wild beasts, which are also called beasts of venery, and beasts of the forest.

VENESECTON, or PHLEBOTOMY, in surgery. See PHLEBOTOMY.

VENETA Bolus, the *Venetian bole*, a fine red earth used in painting, and called in the colour-shops Venetian red. It is improperly denominated a bole, being a genuine species of red ochre. It is of a fine bright, and not very deep red, approaching, in some degree, to the colour of minium, or red-lead, and is moderately heavy, and of an even and smooth texture, yet very friable, and of a dusty surface: it adheres firmly to the tongue, is very smooth and soft to the touch, easily crumbles to pieces between the fingers, and very much stains the skin in handling. It has a slight astringent taste, and makes no fermentation with acids. It is dug in Carinthia, and sent from Venice to all parts of the world, being an excellent colour; and very cheap; our colourmen however find many ways of adulterating it.

VENIAL, in the Romish theology, a term applied to slight sins, and such as easily obtain pardon. In confessing

feeling to the priests, people are not obliged to accuse themselves of all their venial sins. The thing that gives the greatest embarrass to the Romish casuists, is to distinguish between venial and mortal sins. The reformed reject this distinction of venial and mortal sins, and maintain, that all sins, how grievous soever, are mortal. And the reason they urge is, that all sins, though of their own nature mortal, yet become venial or pardonable, by virtue of our Saviour's passion, to all such as fulfil the conditions on which it is offered in the Gospel.

VENT, VENT-HOLE, or SPIRACLE, a little aperture left in the tubes or pipes of fountains, to facilitate the air's escape; or, on occasion, to give them air, as in frosty weather, &c. for want of which they are apt to burst.

Vent is likewise applied to the covers of wind furnaces, whereby the air enters, which serves them for bellows, and which are stopped with registers or sluices, according to the degree of heat required, as in the furnaces of glass-houses, assayers, &c.

VENTER, BELLY, in anatomy, a cavity in the body of an animal, containing viscera, or other organs necessary for the performance of divers functions.

Physicians divide the human body into three venters, regions, or cavities; the first, the head, containing the brain, &c.

The second, the breast, or thorax, as far as the diaphragm, containing the organs of respiration.

The third, which is what we call the venter, or belly, is that wherein the intestines and organs of generation and digestion are contained; called, by anatomists, the abdomen.

VENTER is also used in speaking of a partition of the effects of a father and mother, among children born, or accruing from different marriages.

VENTER is also used for the children whereof a woman is delivered at one pregnancy: thus, two twins are said to be of the same venter.

VENTER, or BELLY of a muscle, is the fleshy or belly-part thereof, as contradistinguished from the two tendons, its extremes, one of which is called the head, and the other the tail, of the muscle.

VENTER DRACONIS, DRAGON'S BELLY, in astronomy, denotes the middle of a planet's orbit, or that part most remote from the nodes, that is, from the dragon's head and tail; being the part which has the greatest latitude, or is at the greatest distance from the ecliptic.

VENTIDUCTS, in building, are spiracles or subterraneous places, where fresh, cool wind being kept, they are made to communicate, by means of tubes, funnels, or vaults, with the chambers or other apartments of a house, to cool them in sultry weather.

VENTILATOR, a machine by which the noxious air of any close place, as an hospital, goal, ship, chamber, &c. may be changed for fresh air. The noxious qualities of bad air have been long known, though not sufficiently attended to, in practice; but it is to be hoped that the indefatigable pains taken by Dr. Hales, to set the mischiefs arising from foul air in a just light, and the remedy he has proposed by the use of his ventilators, will at length prevail over that unaccountable sloth or obstinacy, which, where particular interests are not concerned, seems to possess the generality of mankind, and which rarely allows them to give due attention to any new discovery. The ventilators invented by that ingenious gentleman, consist of a square box, A B C D (plate CXXXIV. fig. 5.) about ten feet long, five wide, and two deep; in the middle of which is placed a broad partition, or midriff, made to move up and down, from A to C, on hinges at the end E, by means of an iron rod Z R, fixed to the midriff at Z. Another box, of the same size with the former, having a like midriff, bar, &c. is placed near the former, (fig. 6.) with its rod R Z. Both these rods are fixed to a lever F G, moveable on the center O; so that by the alternate rising and depressing of the lever F G, the midriffs are also raised and depressed alternately, by which means these double bellows are at the same time both drawing and pouring out the air. That the midriffs may be rendered lighter, they may be made of

four bars lengthwise, and as many placed across them, each about three inches broad, and an inch thick, the vacant spaces being filled up with thin pannels of fir-board.

In order to make the midriffs move with greater ease, and without touching the sides of the boxes, there is an iron regulator N L, (fig. 5.) fixed upright to the middle of the end A C of the box. As very little air will escape if the edges of the midriff be within one twentieth part of an inch from the sides of the box, there is no necessity for leathern sides, as in common bellows. The end A C of the box must be somewhat circular, that it may be the better adapted to the rising and falling of the midriff; and at the other end of the midriff a slip of leather may be nailed over the hinges.

To the ventilators above described, eight valves are adapted for the air to pass thro'; these valves are placed at the hinge end B Q, (fig. 6.) numbered 1, 2, 3, 4, &c. The valve 1 opens inward, to admit the air to enter, when the midriff is depressed at the other end, by means of the lever F G; and at the same time the valve 3, in the lower ventilator, is shut by the compressed air, which passes out at the valve 4: but when that midriff is raised, the valve 1 shuts, and the air passes out at the valve 2. The same is to be observed of the valves 5, 6, 7, 8, of the other box; so that when by the motion of the lever F G, the midriffs are alternately rising and falling, then two of the ventilators are constantly drawing in the air, and two of them at the same time are blowing it out at their proper valves, the air entering at the valves 1, 3, 6, 8, and passing out at the valves 2, 4, 5, 7. To the ventilators, before the valves, is fixed a box Q Q M M, (fig. 7) as a common receptacle for all the air that comes out of these valves, which air is conveyed away through the trunk P, passing through the wall of a building, &c.

From the foregoing explanation, the nature of ventilators may be easily understood, and therefore we shall be briefer in the following description of those lately erected in Newgate, for exhausting that prison of its foul air. In this prison then there are seven ventilators, each nine feet long, and four feet and a half wide; two pair of which are laid on each other; these ventilators are worked by means of a wind-mill.

The valves of the ventilators open into a large wooden box A B (fig. 8.) which is fastened to the ventilators by the hooks A A: this box is divided into three spaces; the middle, or largest, C C, receives all the foul air discharged by the ventilators, whence it passes through a trunk D D, sixteen inches wide, through the leads into the open air.

The outer spaces B B B B, receive the foul air through the trunks F F, from the several wards, from whence it is conveyed into the ventilators, through those valves which open inward, and then discharged by the other valves of the ventilators, into the middle partition of the box, and from thence conveyed, by the pipe D D, into the open air.

These ventilators are fixed in an upper room of Newgate, in order to be near the leads, where the wind-mill, which works them, is erected; and from each of the outer nostrils F F, there are trunks, with sliding shutters, passing into the several wards; so that by opening these trunks, any of the wards may be ventilated, either singly, or several at a time.

That the midriffs may not be spoiled for want of air, when all the trunks are shut, there are two holes cut in the outer nostrils, at E E, which are covered with boxes twenty inches long, and fourteen wide. In the bottom of each of these boxes is a large moveable valve, of such a weight as not to open but when all the other passages for the air are stopped; by means of these valves, the ventilators are supplied with air, when all the trunks, going into the several wards, are closed, and the midriffs are not in danger of breaking for want of it.

The wind-mill (fig. 9.) erected for working the ventilators, is designed to move with a small degree of wind, that the ventilators may be the oftener worked.

The mill-post is fixed on four cross-trees, and supported by the braces u w x y.

This

This post is hollow, that the iron rod *a*, may pass through, the lower end of it being fixed to the lever of the ventilators.

The upper end of this rod goes to the iron axle-tree, which has a crank six inches long, and therefore gives a stroke of thirteen inches; and the other end being fixed to the lever, at a proper distance from the center of its motion, raises the midribs fifteen inches.

The iron axle-tree extends about two feet beyond the face of the sails, from the extremity of which, *p*, eight iron braces go to the vanes, *m, n, o, p, q, r, s*, &c.

The frame turns on the post, on friction-wheels, so that the sails always face the wind, by means of the vane *i*; *l* is the break-pole, which, by pulling the rope *k*, stops the mill; *b, d, c, e*, are iron braces, fastened at each end with iron bolts, to keep the frame from wracking. See the article WIND-MILL.

Fig. 10. represents an instrument invented for going with safety into damps, and other noxious air. *XZ* represents a square piece of elder, or willow, a foot long, and two inches both in breadth and depth, with a hole, *KLQU*, five eighths of an inch diameter, bored thro' it; and, at *CD*, short foffets, with like holes bored through them; to which foffets hollow reed-canes are to be fixed by means of short supple leathern pipes, so as to be flexible at these joints. *N, T, S*, are square holes, two inches deep, and an inch and three quarters wide, with their leathern covers *F, G, H, I*, nailed over them. *IN* is a broad leathern valve, moving on joints at *I*, so as to open, by the force of the air, which passes down the pipe *BKL*, when the breath is drawn in at the mouth at the middle foffet, which stands five eighths of an inch above *GH*. *GS* is another like valve, which shuts the hole, at *Q*, close, while the breath is drawing in, through the middle foffet; but when, on the contrary, the person breathes out through the middle foffet; the valve *IN* closes the hole *L*, and the other valve *GS* opens for the breath to pass freely off through the pipe *UA*; by which means the person always draws in fresh air. There are two stiff wires, as *T*, fixed to prevent the valves opening too far, lest the force of the breath, which is but small, should not shut them: this instrument is to be fixed to the mouth by a tape, or cord, tied round the head; and it will be convenient to have cushions at the corners *C* and *D*, for the cheeks to bear off a part of the pressure. By the help of this instrument a person may go into a suffocating air, as in some mines, &c. his nostrils being stopped with cotton, without any danger of suffocation.

VENTRICLE, *Ventriculus*, properly denotes any little cavity; but is more particularly used, by physicians and anatomists, for the stomach. See STOMACH.

For those cavities of the heart and brain, called ventricles, see HEART and BRAIN.

VENTRILOQUOUS, a term applied to persons who speak inwardly, having a peculiar art of forming speech, by drawing the air into the lungs; so that the voice proceeding out of the thorax, to a by-stander seems to come from a distance.

The word is compounded of *venter*, belly, and *loquor*, I speak.

Such a person we had sometime ago in London, a smith by profession, who had the faculty in such perfection, that he could make his voice appear, now, as if it came out of the cellar; and the next minute, as if in an upper room; and no body present could perceive that he spoke at all: accordingly, he has frequently called a person first up, then down stairs; then out of doors, then this way, then that, and all this without stirring from his seat, or appearing to speak at all.

VENTURINE, or ADVENTURINE, is sometimes used for the finest and slenderest gold wire used by embroiderers. See WIRE.

VENUS, in astronomy, one of the inferior planets, revolving round the sun, in an orbit between that of Mercury and the earth.

Venus is computed to be fifty-nine millions of miles from the sun; and by moving at the rate of 69,000 miles every hour in her orbit, she goes round the sun in 224 days, 17 hours, of our time nearly; in which, though it be the full length of her year, she has only $9\frac{1}{4}$ days, ac-

cording to Bianchini's observations; so that in her every day and night together is as long as $24\frac{1}{4}$ days and nights with us. This odd quarter of a day in every year makes every fourth year a leap-year to Venus; as the like does to our earth. Her diameter is 7906 miles; and by her diurnal motion the inhabitants about her equator are carried 43 miles every hour; besides the 69,000 above mentioned.

Her orbit includes that of Mercury within it; for at her greatest elongation, or apparent distance from the sun, she is 96 times his breadth from his center; which is almost double of Mercury's. Her orbit is included by the earth's; for if it were not, she might be seen as often in opposition to the sun as in conjunction with him; but she was never seen 90 degrees, or a fourth part of a circle, from the sun.

When Venus appears west of the sun, she rises before him in the morning, and is called the morning star; when she appears east of the sun, she shines in the evening after he sets, and is then called the evening star; being each in its turn for 290 days. It may perhaps be surprising at first, that Venus should keep longer on the east or west of the sun than the whole time of her period round him. But the difficulty vanishes when we consider that the earth is all the while going round the sun the same way, tho' not so quick as Venus: and therefore her relative motion to the earth must in every period be as much slower than her absolute motion in her orbit, as the earth during that time advances forward in the ecliptic; which is 220 degrees. To us she appears through a telescope in all the various shapes of the moon.

The axis of Venus is inclined 75 degrees to the axis of her orbit; which is $51\frac{1}{2}$ degrees more than our earth's axis is inclined to the axis of the ecliptic: and therefore the variation of her seasons is much greater than of ours. The north pole of her axis inclines toward the 20th degree of Aquarius, our earth's to the beginning of Cancer: and therefore the northern parts of Venus have summer in the signs where those of our earth have winter, and *vice versa*.

The artificial day at each pole of Venus is as long as $112\frac{1}{2}$ natural days on our earth,

The sun's greatest declination on each side of her equator amounts to 75 degrees; therefore her tropics are only 15 degrees from her poles; and her polar circles as far from her equator. Consequently, the tropics of Venus are between her polar circles and her poles; contrary to what those of our earth are.

As her annual revolution contains only $9\frac{1}{4}$ of her days, the sun will always appear to go through a sign, or twelfth part of her orbit, in little more than three quarters of her natural day, or nearly in $18\frac{1}{4}$ of our days and nights.

Because her day is so great a part of her year, the sun changes his declination in one day so much, that if he passes vertically, or directly over head of any given place on the tropic, the next day he will be 26 degrees from it: and whatever place he passes vertically over when in the equator, one day's revolution will remove him $36\frac{1}{4}$ degrees from it. So that the sun changes his declination every day in Venus about 14 degrees more at a mean rate, than he does in a quarter of a year on our earth. This appears to be providentially ordered, for preventing the too great effects of the sun's heat, which is twice as great on Venus as on the earth; so that he cannot shine perpendicularly on the same places for two days together; and by that means, the heated places have time to cool.

If the inhabitants about the north pole of Venus fix their south, or meridian line, through that part of the heavens where the sun comes to his greatest height, or north declination, and call those the east and west points of their horizon, which are 90 degrees on each side from that point where the horizon is cut by the meridian line, these inhabitants will have the following remarkables.

The sun will rise $22\frac{1}{2}$ degrees north of the east, and going on $112\frac{1}{2}$ degrees, as measured on the plane of the horizon, he will cross the meridian at an altitude of $12\frac{1}{2}$ degrees; then making an entire revolution without setting, he will cross it again at an altitude of $48\frac{1}{2}$ degrees; at the next revolution he will cross the meridian as he comes

comes to his greatest height and declination, at the altitude of 75 degrees; being then only 15 degrees from the zenith, or that point of the heavens which is directly over head: and thence he will descend in the like spiral manner; crossing the meridian first at the altitude of $48\frac{1}{2}$ degrees; next at the altitude of $12\frac{1}{2}$ degrees; and going on thence $112\frac{1}{2}$ degrees, he will set $22\frac{1}{2}$ degrees north of the west; so that, after having been $4\frac{1}{2}$ revolutions above the horizon, he descends below it to exhibit the like appearances at the south pole.

At each pole, the sun continues half a year without setting in summer, and as long without rising in winter; consequently the polar inhabitants of Venus have only one day and one night in the year; as it is at the poles of our earth. But the difference between the heat of summer and cold of winter, or of mid-day and midnight, on Venus, is much greater than on the earth: because in Venus, as the sun is for half a year together above the horizon of each pole in its turn, so he is for a considerable part of that time near the zenith; and during the other half of the year, always below the horizon, and for a great part of that time at least 70 degrees from it. Whereas, at the poles of our earth, although the sun is for half a year together above the horizon, yet he never ascends above, nor descends below it, more than $23\frac{1}{2}$ degrees. When the sun is in the equinoctial, or in that circle which divides the northern half of the heavens from the southern, he is seen with one half of his disc above the horizon of the south pole; so that his center is in the horizon of both poles: and then descending below the horizon of one, he ascends gradually above that of the other. Hence, in a year, each pole has one spring, one harvest, a summer as long as them both, and a winter equal in length to the other three seasons.

At the polar circles of Venus, the seasons are much the same as at the equator, because there are only 15 degrees betwixt them: only the winters are not quite so long, nor the summers so short: but the four seasons come twice round every year.

At Venus's tropics, the sun continues for about fifteen of our weeks together without setting in summer; and as long without rising in winter. Whilst he is more than 15 degrees from the equator, he neither rises to the inhabitants of the one tropic, nor sets to those of the other: whereas, at our terrestrial tropics he rises and sets every day of the year.

At Venus's tropics, the seasons are much the same as at her poles; only the summers are a little longer, and the winters a little shorter.

At her equator, the days and nights are always of the same length; and yet the diurnal and nocturnal arches are very different, especially when the sun's declination is about the greatest: for then, his meridian altitude may sometimes be twice as great as his midnight depression, and at other times the reverse. When the sun is at his greatest declination, either north or south, his rays are as oblique at Venus's equator, as they are at London on the shortest day of winter. Therefore, at her equator there are two winters, two summers, two springs, and two autumns every year. But because the sun stays for some time near the tropics, and passes so quickly over the equator, every winter there will be almost twice as long as summer: the four seasons returning twice in that time, which consists only of $9\frac{1}{4}$ days.

Those parts of Venus which lie between the poles and tropics, and between the tropics and polar circles, and also between the polar circles and equator, partake more or less of the phenomena of these circles, as they are more or less distant from them.

From the quick change of the sun's declination it happens, that when he rises due east on any day, he will not set due west on that day, as with us; for if the place where he rises due east be on the equator, he will set on that day almost west-north-west; or about $18\frac{1}{2}$ degrees north of the west. But if the place be in 45 degrees north latitude, then on the day that the sun rises due east he will set north-west by west, or 33 degrees north of the west. And in 62 degrees north latitude when he rises in the east, he sets not in that revolution, but just touches

the horizon 10 degrees to the west of the north point; and ascends again, continuing for $3\frac{1}{4}$ revolutions above the horizon without setting. Therefore, no place has the forenoon and afternoon of the same day equally long, unless it be on the equator or at the poles.

The sun's altitude at noon, or any other time of the day, and his amplitude at rising and setting, being so different at places on the same parallels of latitude, according to the different longitudes of those places, the longitude will be almost as easily found on Venus as the latitude is found on the earth: which is an advantage we can never enjoy, because the daily change of the sun's declination is by much too small for that purpose.

On this planet, wherever the sun crosses the equator in any year, he will have 9 degrees of declination from that place on the same day and hour next year; and will cross the equator 90 degrees farther to the west; which makes the time of the equinox a quarter of a day, almost equal to six of our days, late every year. Hence, although the spiral in which the sun's motion is performed, be of the same sort every year, yet it will not be the very same, because the sun will not pass vertically over the same places till four annual revolutions are finished.

We may suppose that the inhabitants of Venus will be careful to add a day to some particular part of every fourth year; which will keep the same seasons to the same days. For, as the great annual change of the equinoxes and solstices shifts the seasons a quarter of a day every year, they would be shifted though all the days of the year in 36 years. But by means of this intercalary day, every fourth year will be a leap-year; which will bring her time to an even reckoning, and keep her calendar always right.

Venus's orbit is inclined $3\frac{1}{2}$ degrees to the earth's; and crosses it in the 14th degree of Gemini and of Sagittarius; and therefore, when the earth is about these points of the ecliptic at the time that Venus is in her inferior conjunction, she will appear like a spot on the sun, and afford a more certain method of finding the distances of all the planets from the sun than any other yet known. But these appearances happen very seldom; and will only be twice visible at London for 300 years to come. The first time will be in 1996, June the 9th, at 2 hours 13 minutes in the afternoon. And the second in the year 2004, June the sixth, at 7 hours 18 minutes in the forenoon. Excepting such transits as these, she shews the same appearances to us regularly every eight years; her conjunctions, elongations, and times of rising and setting being very nearly the same, on the same days, as before.

Venus may have a satellite or moon, although it be undiscovered by us: which will not appear very surprising, if we consider how inconveniently we are placed for seeing it. For its enlightened side can never be fully turned towards us but when Venus is beyond the sun; and then, as Venus appears little bigger than an ordinary star, her moon may be too small to be perceptible at such a distance. When she is between us and the sun, her full moon has its dark side towards us; and then we cannot see it any more than we can our own moon at the time of change. When Venus is at her greatest elongation, we have but one half of the enlightened side of her full moon towards us; and even then it may be too far distant to be seen by us. But if she has a moon, it may certainly be seen with her upon the sun, in the year 1996, unless its orbit be considerably inclined to the ecliptic: for if it should be in conjunction or opposition at that time, we can hardly imagine that it moves so slow as to be hid by Venus all the six hours that she will appear on the Sun's disc.

VENUS, in chemistry, the same with copper. See COPPER.

VERATRUM, white hellebore, in botany, a genus of plants producing hermaphrodite and male flowers on the same plant, each containing six oblong, lanceolated, persistent petals, with six subulated filaments topped with quadrangular antheræ; the male flower is barren, but the hermaphrodite is succeeded by three oblong, erect, compressed capsules, each having but one cell, containing many oblong, compressed, membranaceous seeds.

White

White hellebore root is oblong and tuberoso, dusky without and white within, with a great number of whitish fibres; the leaves are oblong, oval, large, rounded at their extremities, and have many longitudinal plaits; the stalks rise to about three or four feet high, branching out on every side; under each branch is placed a narrow plaited leaf; the branches and stalk are terminated with spikes of flowers, which appear in June and July. It grows naturally in several parts of Germany and Switzerland; the root is the only part used in medicine; the taste is acrid, a little bitterish, subastringent, disagreeable and nauseous; the inward use is not very safe, nor indeed the outward; for when the powder is applied to an issue, it will occasion violent purging; when taken inwardly, it is a strong emetic, and has been observed sometimes to occasion convulsions and other terrible disorders; however, in desperate cases, it may be sometimes ventured upon, particularly against madness: the dose in this disease is a scruple; though even in this case it must be used with the utmost caution. See HELLEBORE.

VERB, in grammar, a word serving to express what we affirm of any subject, or attribute to it; or, according to others, it is a word principally used to signify the affirmation, and shews that the discourse, wherein it is used, is that of a man, who not only has a conception of things, but judges or affirms something of them: though it is principally used in this sense, yet it is made use of also to signify other motions of the soul, as to desire, to pray, to command; but this it only does by changing the mood or inflexion.

The verb, in its primary signification, should have no other use, but to mark the connection which we make in the mind, between the two terms of a proposition; but the *esse, to be*, is the only one that has retained this simplicity; nor, in strictness, has this retained it, but in the third person, as *est, is*. Men being naturally inclined to shorten their expressions, to the affirmation they have almost always added other significations, in the same word, so as that two words make a proposition; as in *Petrus vivit, Peter lives*; where *vivit* includes both the attribute and affirmation; it being the same thing to say, *Peter lives*, as that *Peter is living*; and hence the great variety of verbs in every language.

To consider simply what is essential to a verb, the only true definition is, a word signifying an affirmation; but if we should chuse to add its principal accidents, it may be defined thus; a word which signifies affirmation, with the designation of person, number, and time.

Verbs are variously divided; with respect to the subject, they are divided into active, passive, neuter, &c. with respect to their inflections, into regular, irregular, personal, impersonal, auxiliary, substantive, &c.

A verb active is a verb which expresses an action that falls on another subject or object; such as, *I love, I work*, &c. which signify the action of loving, working, &c. Of these there are three kinds; the one called transitive, where the action passes to a subject different from the agent; and reflected, where the action returns upon the agent; and reciprocal, where the action returns mutually upon the two agents that produced it.

A verb passive is that which expresses a passion, or which receives the action of some agent; and which is conjugated in the modern tongues, with the auxiliary verb *I am, je suis*.

A verb neuter, is that which signifies an action that has no particular object whereon to fall, but which of itself takes up the whole idea of the action, as, *I sleep, thou yawnest, he snores, we walk, you run, they stand*: the Latins called them neuters, because they are neither active nor passive, though they have the force and signification of both.

Of these verbs, some form their tenses by the auxiliary verb *to have*, as *I have slept, ye have run*; and they are called neuter actives. There are others which form their compound parts by the auxiliary *to be*, as *I am come*; these are called neuters passive.

A verb substantive is that which expresses the being or existence of a thing, as *I am, thou art*.

Auxiliary or helping verbs, are those which serve in conjugating active and passive verbs, such as *I am, I have*, &c.

Verbs in English, and most modern tongues, do not change their terminations, as in Latin, to express the several times, modes, &c. but they make use of auxiliaries, as *have, am, be, do, will, shall*, &c.

Regular verbs are those which are conjugated after some one manner, rule, or analogy.

Irregular or anomalous verbs, are such as have something singular in the terminations or formations of their tenses.

Verbs impersonal are those which have only the third person, as *it behaves*, &c.

VERBAL, something that belongs to verbs, or even to words of any kind spoken with the mouth.

Thus, verbal nouns, among grammarians, are those formed of verbs.

Again, a verbal contract is one made merely by word of mouth, in opposition to that made in writing.

VERBASCUM, mullein, in botany, a plant, all over white and woolly; with a single woody stalk, clothed with oblong oval leaves joined to it without pedicles, bearing on the top a long spike of large yellow monopetalous flowers cut into five segments, and followed by conical seed vessels. It is biennial, grows wild by road sides, and flowers in July.

The leaves of mullein, recommended as mild astringents, have a roughish drying kind of taste, and very little smell. The flowers have also a slight roughishness, with a considerable sweetness.

VERBENA, vervain, in botany, a genus of plants, with wrinkled, oblong, obtuse leaves, deeply jagged and indented, set in pairs on the stalks, the upper ones divided into three segments: on the tops of the branches appear irregularly labiated blue flowers, in long spikes, without any leaves among them, followed each by four seeds inclosed in the cup. It is annual, grows wild in uncultivated places, and flowers in July or August.

This plant has been celebrated for abundance of virtues, for which its sensible qualities afford little or no foundation. It has no remarkable smell, and hardly any taste.

VERBERATION, *Smiting*, in physics, a term used to express the cause of sound, which arises from a verberation of the air, when struck in divers manners by the several parts of the sonorous body first put into a vibratory motion.

VERDEGREASE, or VERDEGRIS, a kind of copper corroded by a fermented vegetable acid into a bluish green substance. The greatest quantities are prepared about Montpellier, by stratifying copper plates with grape-stalks, that have been previously soaked in strong wine, and exposed to its vapour during a second fermentation of the wine continued to an acetous state: the subtil acid, with which the stalks are thus impregnated, corrodes the surface of the plates, in a few days, into verdegris: which is afterwards scraped off, moistened, and packed up in skins. The masses, as brought to us, have generally some grape stalks intermixed: these may be separated by pulverization, as being less pulverable than the verdegris itself. The goodness of verdegris is judged of from the deepness and brightness of its colour, its dryness, and its forming, when rubbed on the hand with a little water or saliva, a smooth paste free from grittiness.

This concrete is partially dissoluble in water and in rectified spirit, and almost totally in vinegar: from the acetous solution duly inspissated and set to shoot, greatest part of the verdegris may be recovered in a crystalline form. The crystals, distilled with a suitable fire, in a retort or other like vessel, give over the acetous acid, in a highly concentrated state, but somewhat altered by the process.

Verdegris is employed externally for detarging foul ulcers and as an elcharotic. Hoffmann recommends it particularly for destroying the callosities of old fistulæ: tents of powdered verdegris, made up with saliva, or other liquids not fat or oily, exude, he says, the hardest callus, in three or four days, so as to render it completely separable. A detergent ointment is commonly prepared, by gently boiling five parts of verdegris in fine powder, with sixteen of honey and seven of vinegar, till reduced to a due consistence. On keeping this mixture

ture for some time, a thick matter, containing greatest part of the verdegris, falls to the bottom, and a thinner floats on the top: this last is the part made use of, unless where particular occasions require it to be rendered more acrid by shaking up the thick among it. When these kinds of applications are employed for venereal or other ulcerations in the mouth and tonsils, great caution is requisite, on the part of the patient, to guard against any portion of them passing into the stomach; an accident which has sometimes happened, particularly in childrens cases, and produced very dangerous and even fatal consequences.

Verdegris is rarely or never given internally. Some recommend it indeed, in the dose of a grain or two, as an emetic, which operates almost as soon as received into the stomach, and which may therefore be of use, where poisonous substances have been taken, to procure their immediate rejection. It appears, however, highly imprudent, to have recourse, on such occasions, to a remedy in itself so dangerous and so virulent; and more especially as a speedy evacuation may generally be obtained, by means of substances, which are not only innocent, but at the same time weaken the force of the poison by diluting and obtunding it; as warm water, milk, oils.

VERDERER, or VERDEROR, a judicial officer of the king's forest, whose business it is to look to the vert, and see it well maintained.

VERDICT, is the answer of the jury given to the court, concerning the matter of fact, in any case civil or criminal, committed by the court to their trial and examination.

A verdict is either general or special. A general verdict is that which is brought into the court in like general terms as the general issue, as, in an action of disseisin, the defendant pleads no wrong, no disseisin. Then the issue is general, whether the fact be wrong or not, which being committed to the jury, they, upon consideration of the evidence, come in and say, either for the plaintiff, that it is a wrong disseisin; or for the defendant, that it is no wrong disseisin.

A special verdict, is, when they say at large, that such and such a thing they found to be done by the defendant or tenant; declaring the course of the fact, as in their opinion it is proved; and praying the judgment of the court, as to what is law in that case.

It is said, that a jury may give a general or special verdict, in all actions, and cases; and that the court is obliged to receive it, provided it be pertinent to the point in issue: also if the jury will take upon them to bring in any thing that is matter of law, their verdict shall be received.

Verdicts are also public and private; public, when the same are given in open court; and private, when given out of court, before any of the judges: but a private verdict, in strictness, is looked upon to be no verdict.

VERDITER, or VERDETER, a kind of mineral substance, sometimes used by the painters, &c. for a blue; but more usually mixed with a yellow for a green colour.

Verditer, according to Savary, ought to be made of the lapis armenus; or at least of an earthy substance much like it, brought from the mountains of Hungary, &c. only prepared by powdering it, and cleansing it by lotion.

But this stone being very rare, the verditer commonly used is not a native, but a factitious, substance; which some say is prepared by casting wine or water upon new copper, as it comes red hot out of the furnace, and catching the steams that rise from it upon copper-plates; others again say, it is prepared by dissolving copper-plates in wine, much after the manner of verdegrease.

But the method of making it in England is as follows:

The refiners pour their copper-water into an hundred pound weight of whiting, stirring them well together every day for some hours, till the water grows pale; then they pour that off, and set it by for further use,

and pour on more of the green water, repeating this till the verditer is made; which they then take out, and lay on large pieces of chalk in the sun to dry.

The water which is poured off from the verditer, which remains at the bottom of the tub, is put into a copper, and boiled till it comes to the consistence of water-gruel; now, consisting principally of salt-petre reduced, most of the spirit of vitriol being gone with the copper into the verditer; and a dish full of this being put into the other materials for aqua-fortis, is redistilled, and makes what they call a double water, which is near twice as good as that made without it.

VERDOY, in heraldry, denotes a bordure of a coat of arms, charged with any kinds or parts of flowers, fruits, seeds, plants, &c.

VERGE, signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household; and which is thought to have been twelve miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand, and swearing fealty to the lord of the manor.

VERGERS, certain officers of the courts of King's Bench and Common Pleas, whose business it is to carry white wands before the judges.

There are also vergers of cathedrals and collegiate churches, who carry a rod tipped with silver before the bishop, dean, &c.

VERGETTE, in heraldry, denotes a pallet, or small pale; and hence, a shield divided by such pallets, is termed vergette.

VERGILÆ, in astronomy, a constellation, the appearance of which denotes the approach of spring: it is the same with pleiades. See the article PLEI-
ADES.

VERIFICATION, in general, is the act of proving a thing; but among the French, it only signifies the recording of the king's edicts by the parliament.

VERJUICE, a juice or liquor drawn from four grapes, or wild apples, unfit for wine, or cyder; or from sweet ones, while yet acid, and unripe.

Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions; and is used by the wax-chandlers to purify their wax.

It has its name from a large sort of grape, called verjus, or bourdelas, which is said never to grow perfectly ripe; or rather, which in its utmost maturity is too austere and sour to be used in wine: whence it is commonly turned into verjuice; though in France all unripe grapes are denominated verjus.

There is also a tolerable juice made of crabs, gathered, and laid in a heap to sweat, the stalks, &c. separated; they are then stamped, or ground, and the crab-mash put in a hair bag; the juice squeezed in a press, then barrelled up close, and set in a warm place to work for ten or twelve days.

VERMICELLI, or VERMICHELLY, a composition of flour, cheese, yolks of eggs, sugar, and saffron, reduced to a paste, and formed into long slender pieces like worms, by forcing it with a piston through a number of little holes.

It was first brought from Italy, where it is in great vogue: it is chiefly used in soups and pottages, to provoke venery, &c.

VERMICULAR, an epithet given to any thing that bears a relation or resemblance to worms, vermiculi. See WORM.

Anatomists particularly apply it to the motion of the intestines and certain muscles of the body.

The vermicular or peristaltic motion of the intestines is performed by the contraction of the fibres thereof, from above downwards; as the antiperistaltic motion is by their contraction from below upwards.

VERMIFORMIS, in anatomy, a term applied to various parts in the human body, bearing some resemblance to worms. As some muscles, processes, &c.

Processus or *Apophyses* VERMIFORMES, two extremities of the cerebellum, situate near the fourth ventricle of the brain. See BRAIN.

VERMIFORMES Musculi, are the four muscles in each hand and foot, which bring the fingers and toes towards the thumbs and great toes, called also *lumbricales*.

VERMILION, a very bright and beautiful colour, in great esteem among the ancients, under the name of *minium*.

There are two kinds of it, the one natural, the other facitious. The natural is found in some silver mines, in the form of a ruddy sand, which is afterwards prepared and purified by several lotions and coctions. The artificial is made of mineral cinnabar, ground up with *aqua-vitæ* and urine, and afterwards dried.

It is also made of lead burnt and washed, or of cerufs prepared by fire: but this is not properly called vermilion, but *minium*, or red-lead.

Yet this last, however, seems to be the real vermilion of the ancients; and both apothecaries and painters still give it the name, to enhance the price.

We have two kinds of vermilion from Holland, the one of a deep red, the other pale; but it is the same thing at the bottom: the only difference of colour proceeding from the cinnabar's being more or less ground: when the cinnabar is finely ground, the vermilion is pale: and this is preferred before that which is coarser and redder.

It is of great use with painters in oil and miniature; and among the ladies for a fucus, or paint, to heighten the complexion of such as are too pale.

Some disapprove of vermilion to be used in painting prints, unless it be prepared by washing, as is directed for *minium*; and then chiefly for dry painting, except it be by those persons who can use it moderately, and with judgment; for all heavy colours will drown the shades or strokes of the engraver.

VERMIN, *Vermina*, a collective name including all kinds of little animals, or insects, which are hurtful or troublesome to men, beasts, fruits, &c. as worms, lice, fleas, caterpillars, ants, flies, &c.

VERMINATION, *Verminatio*, the act of breeding worms, and other vermin; particularly bots, in cattle, &c.

VERMINATION is sometimes also used among physicians, for a sort of *tormina ventris*, or wringing of the guts, wherein the patient is affected, as if worms were gnawing his intestines.

VERMIVOROUS ANIMALS, are such as feed upon worms.

VERNACULAR, is applied to any thing that is peculiar to some one country.

VERNAL, something belonging to the spring season.

Hence vernal leaves, are those leaves of plants which come up in the spring. Vernal signs, are those which the sun is in during the spring season, viz. Aries, Taurus, and Gemini. Vernal equinox, is that which happens when the sun is ascending from the equator towards the north pole.

VERNIER, or **NONIUS**, among mathematicians, a scale of divisions, serving to cut the divisions of an arch into single minutes.

VERONICA, in botany, a genus of plants, the flower of which has a permanent empalement, cut into five acute segments; it has one tubulous petal the length of the empalement; the brim is cut into four oval plain segments, which spread open, and two stamina, which are terminated by oblong summits, with a compressed germen, supporting a slender declining style, crowned by a single stigma. The germen afterwards becomes a compressed heart-shaped capsule with two cells, filled with roundish seeds.

Mr. Miller has enumerated sixteen species of *veronica*, most of which are natives of Europe. These plants may all be propagated by parting their roots, which may be done every year; for if they are not often parted or divided, they will many of them grow too large for the borders of small gardens; but yet they should not be parted into very small heads, because when they have not a number of stems, so as to form a good bunch, they are soon past their beauty, and have but a mean

appearance. The best time to part these roots is at Michaelmas, that they may be well rooted again before winter; for when they are removed in the spring, they seldom flower strong the same year, especially if the season should prove dry. Those sorts which grow pretty tall, are very proper to plant on the sides of open wilderness quarters, but those with trailing branches are fit for the sides of banks or irregular shady slopes, where they will make an agreeable variety; they are all of them very hardy, so are in no danger of suffering by cold, and require no other care but to keep them clean from weeds, and to be transplanted every second year.

They may also be propagated by seeds, which should be sown in autumn, for when they are sown in the spring, the plants rarely come up the same year; but, as most of the sorts propagate very fast by their off-sets, their seeds are seldom sown.

If the plants are placed in a shady border, they will thrive much better than when they are more exposed to the sun, and their flowers will continue much longer in beauty.

The leaves of *veronica* have a weak not disagreeable smell, which in drying is dissipated, and which they give over in distillation with water, but without yielding any separable oil. To the taste they are bitterish and roughish: an extract made from them by rectified spirit is moderately bitter and subastrigent: the watery extract is weaker, though the quantity of both is nearly the same; whence spirit seems to extract their virtue more completely than water. This herb is of great esteem among the Germans, in disorders of the breast both catarrhus and ulcerous, and for purifying the blood and humours: infusions of the leaves, which are not unpalatable, are drank as tea, and are found to operate sensibly by urine.

VER-PUCERON, in natural history, a name given to a kind of insects which are fond of eating the puceron, and destroy them in vast numbers.

They are thus called, as the ant-eater is *formiculis*, from their destroying great numbers of them.

These ver-pucerons are a sort of worms produced from the eggs of flies; and are of two principal kinds; the one having legs, the other none.

VER-POLYPE, in natural history, a name given, by Reaumur and some other authors, to a species of water-worm, by no means to be confounded with the creature called simply the polype, and which is so famous for its reproduction of parts cut off, and for many other singular properties. See **POLYPE**.

This ver-polype is a species of water-worm, produced from the egg of a tipula; and had its name given it from some remarkable productions, placed at the anterior and posterior parts of the body, which are supposed to have some analogy with the parts of the sea-fish called the polypus.

These worms are found in muddy ditches, usually either crawling upon, or buried in the mud. They are of various sizes, from more than an inch in length to a fifth of an inch, and are smooth and even on their surface; they are composed of several rings, as other insects of this kind, and have a brown scaly head, of a regular figure, and much harder than the rest of the body. Just below the head, on the under part of the body, there are placed two membranaceous productions which seem fragments of arms; they are considerably thick, and are cut off obliquely at the ends, and furnished with many hairs. At the other extremity of the body there are placed four other productions, resembling four pieces of cords; two of these are affixed to the middle of the lower side of the last ring but one, and the other two, at the joining of this, to the last ring. The anterior pair serve the creature greatly in its moving, and these hinder ones have their use in fixing that part of the body in the earthy case the creature sometimes makes for itself, while the head is at liberty to move every-where about in search of prey. These hinder ones are broadest at their insertion, and somewhat narrower at the point, and are very flexible and moveable every way.

The anus of the creature is placed near the end of the last ring of the body, and is of a square figure; it is

is surrounded with a number of rigid hairs or spines, and at each corner has a fleshy tubercle, which stands out a considerable way from the level of the body; the two under ones are much larger than the other two, and the creature evidently uses them to push itself forward in its moving about. Probably, however, these parts have some other more important use. The taking in of air or water is likely enough to be the use they are assigned for.

The cells which these creatures usually live in, are composed principally of fragments of a light and spongy earth, and to this they add the broken pieces of sticks and leaves, and other such substances as are just heavy enough to sink in water. Mr. Reaumur suspects that they have a method of spinning some glutinous fluid out of their bowels, to fix these things together with. But, though they usually reside in these cases, they often quit them, and are found swimming about the water, or with their tails at the top, and playing about with their bodies: or at the bottom, crawling on the surface of the mud.

When the creature has lived its destined time in this state, it changes into a nymph, in the case in which it had lived to the time of this change; it throws off the head, and the productions that served as arms, and to fasten it at the bottom of the case. Nature has generally made the nymph and crysalis state of animals a time of rest and incapacity of motion; but in this, as in the great worms, has given even the nymph a locomotive power, and that a very brisk one. The creature, in this state, had sufficient need of it, and could never arrive at its last change without it. When the time of this final change comes on, the nymph rises to the surface of the water, and, a crack opening on the back, the winged insect begins to appear. The getting thoroughly out is a work of time; and this is the most perilous period of the creature's life; for, if the weather be windy, it is commonly blown into the water, and drowned before the hinder parts are loose. *Reaumur. Hist. Inf.*

VERSE, *Versus*, in poetry, a line or part of a discourse, consisting of a number of long and short syllables, which run with an agreeable cadence, the like being also reiterated in the course of the piece.

This repetition, according to F. Bosliu, is necessary to distinguish the notion of verse from that of prose; for in prose, as well as verse, each period and member are parts of discourse, consisting of a certain number of long and short syllables; only prose is continually diversifying its measures and cadences, and verse regularly repeating them. This repetition of the poets appears even in the manner of writing; for one verse being finished, they return to the beginning of another line, to write the verse following, and it is to this return, that verse owes its name.

To make verse, it is not enough that the measures and quantities of syllables be observed, and six just feet put one after another in the same line. There are further required, certain agreeable cadences, particular tenues, moods, regimens, and even sometimes words unknown in prose. But what is chiefly required, is an elevated, bold, figurative manner of diction; this manner is a thing so peculiar to this kind of writing, that without it, the most exact arrangements of longs and shorts does not constitute verse so much as a sort of measured prose. The Greek and Latin verses consist of a certain number of feet, disposed in a certain order; and some have attempted to make French and English verses on the same foundation, but without success. Vossius is very severe on the modern verse, and makes it altogether unfit for music. Our verses, says he, run all as it were upon one foot, without distinction of members or parts, and without regard to the natural quantities of syllables. We have no rhythmus at all, and we mind nothing but to have a certain number of syllables in a verse of whatever nature, and in whatever order. Mr. Malcolm vindicates our verse from this imputation. It is true, says he, we do not follow the metrical composition of the ancients, yet we have such a mixture of strong and soft, long and short, syllables, as make our verses flow smooth or rumbling, slow or rapid, agreeable to the

subject. Instances of all which we have in the following lines of Pope.

These equal syllables alone require,
Tho' oft' the ear the open vowels tire,
While expletives their feeble aid do join,
And ten low words oft' creep in one dull line.
Soft is the strain when Zephyr gently blows,
And the smooth stream in smoother numbers flows;
But when loud billows lash the sounding shore,
The hoarse rough verse should like the torrent roar;
When Ajax strives some rock's vast weight to throw,
The line too labours, and the words move slow.
Not so when swift Camilla scours the plain,
Flies o'er th' unbending corn, and skims along the main.

By making a small change or transposition of a word in any of these verses, any body who has an ear will find, that we make a great matter of the nature and order of the syllables. See NUMBERS.

Vossius adds, that the ancient odes were sung as to the rhythmus, in the same manner as we scan them, every pes being a distinct bar, or measure separated by a distinct pause, though in reading, that distinction was not accurately observed. Lastly, he observes, that their odes had a regular return of the same kind of verse, and the same quantity of syllables, in the same place of every verse; and whereas, in the modern odes, to follow the natural quantity of our syllables, every stanza would be a distinct song.

Verses are of various kinds, some denominated from the number of feet, whereof they are composed, as the monometer, dimeter, trimeter, tetrameter, pentameter, hexameter, &c.

Some also, from the kinds of feet used in them, as the pyrrhichion, proceleusmatic, iambic, trochaic, &c.

Sometimes verses are denominated from the names of the inventors, or the authors who have used them with most success, as the anacreontic, archilochian, asclepia, alcaic, sapphic, &c.

The moderns have invented heroic or alexandrine verses; the ancients likewise invented various kinds of poetical devices in verse, as centos, echos, &c.

VERSE is also used for a part of a chapter, section, or paragraph, subdivided into several little articles.

The whole bible is divided into chapters, and the chapters are subdivided into verses. The division of verses in the New Testament was first made by one Robert Stephens, with which division many learned men find great fault, and yet it is every where followed.

VERSED *Sine of an Arch*, a segment of the diameter of a circle, lying between the foot of a right line, and the lower extremity of the arch. See the article SINE.

VERSIFICATION, the art or manner of making verse; also the tone and cadence of verse.

Verification is properly applied to what the poet does more by labour, art, and rule, than by invention, and the genius or furor poeticus. See the articles POETRY, &c.

VERSION, a translation of some book or writing, out of one language into another.

VERT, in heraldry, the term for a green colour. It is called vert in the blazon of the coats of all under the degree of nobles; but in coats of nobility, it is called emerald; and in those of kings, venus. In engraving, it is expressed by diagonals, or lines drawn athwart, from right to left, from the dexter chief corner to the sinister base.

VERT, or GREEN HUE, in forest law, any thing that grows and bears a green leaf within the forest, that may cover a deer. This is divided into over-vert, and nether-vert; over-vert is the great woods which in law-books are usually called hault-bois; nether-vert is the under-woods, otherwise called sub-bois. We sometimes also meet with special vert, which denotes all trees growing in the king's woods within the forest; and those which grow in other men's woods, if they be such trees as bear fruit to feed the deer.

VERTEBRÆ,

VERTEBRÆ, a chain of little bones reaching from the top of the neck down the back to the os sacrum, and forming a third part of the human skeleton called the spina dorsi.

They have their name à *vertendo*, because it is on them the head and trunk turn; the Greeks call them σπονδυλοί, spondyli, for the same reason.

The vertebræ are twenty-four in number; seven of them belong to the neck, twelve to the back, and five to the loins, &c.

They lie in a strait line, those of the neck bend inward, and those of the back outwards, for enlarging the cavity of the thorax; and those again of the loins bend inwards, and those of the os sacrum outward, to enlarge the cavity of the basin.

In each vertebræ, we distinguish two parts, the body of the vertebræ, and its processes; the body is softer and more spongy than the processes, which are harder and more solid. The fore-part of the body is round and convex, the hinder-part somewhat concave; its upper and lower sides are plain, each covered with a cartilage, which is pretty thick forwards, but thin backwards, by which means we bend our body forwards: for the cartilages yield to the pressure of the bodies of the vertebræ, which in that motion come closer to one other. This could not be effected, if the harder bodies of the vertebræ were close to one another. Each vertebræ has three sorts of processes towards its hinder part, two transverse or lateral, one on each side; they are nearer the body of the vertebra than the rest. In each of them there is a tendon of the vertebral muscles inserted. Four oblique processes, two on the upper part, and two on the lower, by these vertebræ are articulated to one another; and one acute on the hindmost part of the vertebra. These processes, with the hinder or concave part of the body of the vertebræ, form a large hole in each vertebra, and all the holes answering one another, make a channel for the descent of the spinal marrow, which sends out its nerves to the several parts of the body by pairs, through two small holes formed by the joining of four notches in the sides of each superior and inferior vertebra. The vertebræ are articulated to one another by a ginglymus; for the two descending oblique processes of each superior vertebra of the neck and back have a little dimple in their extremities, wherein they receive the extremities of the two ascending oblique processes of the inferior vertebra; so that the two ascending processes of each vertebra of the neck and back are received, and the two descending do receive, except the first of the neck, and last of the back; but the ascending processes of each vertebra of the loins receive, and the two descending are received contrary to those of the neck and back. The vertebræ are all tied together by a hard membrane made of strong and large fibres: it covers the body of all the vertebræ forwards, reaching from the first of the neck to the os sacrum: there is another membrane which lines the canal, made by the large hole of each vertebra, which also ties them all together. Besides, the bodies of each vertebra are tied to one another by the intervening cartilages; and the tendons of the muscles, which are inserted in their processes, tie them together behind. This structure of the spine is the very best that can be contrived; for had it been all one bone, we could have had no motion in our backs; had it been of two or three bones articulated for motion, the medulla spinalis must have been necessarily bruised at every angle or joint: besides, the whole would not have been so pliable for the several postures we have occasion to put ourselves in. If it had been made of several bones without intervening cartilages, we should have had no more use of it, than if it had been but one bone. If each vertebra had had its own distinct cartilages, it might have been easily dislocated. And, lastly, the oblique processes of each superior and inferior vertebra keep the middle one, that it can neither be thrust backwards nor forwards to compress the medulla spinalis. Thus much of the vertebræ in general; but, because they are not all alike, we shall therefore descend to a more particular examination. The seven vertebræ of the neck differ from the rest in this, that they are smaller and harder. Secondly, that their transverse pro-

cesses are perforated for the passage of the vertebral vessels. Thirdly, that their acute processes are forked and straight; but, besides this, the first and second have something peculiar to themselves. The first, which is called atlas, is tied to the head, and moves with it upon the second semicircularly; its ascending oblique processes receive the tubercles of the occiput, upon which articulation the head is only moved forwards and backwards; and its descending processes receive the ascending processes of the second vertebra. It has no acute process, that it might not hurt the action of the muscoli recti; but a small tubercle, to which the small ligament of the head is inserted. In the fore part of its great hole it has a pretty large sinus, in which lies the tooth-like process of the second vertebra, being fastened by a ligament that rises from each side of the sinus, that it compresses not the medulla spinalis. It has two small sinus's, in its upper part, in which the tenth pair of nerves and the vertebral arteries lie. The second is called epistropheus, or vertebra dentata; in the middle between its two oblique ascending processes, it has a long and round process like a tooth, which is received into the foresaid sinus; upon it the head with the first vertebra turns half round, as upon an axis. The extremity of this process is knit to the occiput by a small but strong ligament. A luxation of this tooth is mortal, because it compresses the medulla spinalis. The third vertebra is called axis; and the four following have no name, nor any peculiar difference. The twelve vertebræ of the back differ from the rest in this, that they are larger than those of the neck, and smaller than those of the loins; their acute processes slope downwards upon one another: they have in each side of their bodies a small dimple, wherein they receive the round extremities of the ribs; and another in their transverse processes, which receives the little tubercle near that extremity of the ribs. The articulation of the twelfth with the first of the loins is by arthrodia, for both its ascending and descending oblique processes are received. The five vertebræ of the loins differ from the rest in this, that they are the broadest, and the last of them is the largest of all the vertebræ. Their acute processes are broader, shorter, and wider from one another, their transverse longer, to support the bowels, and the muscles of the back; they are not perforated as those of the neck, nor have they a dimple or sinus, as those of the back. The cartilages which are betwixt their bodies are thicker than any of the rest. The vertebræ of the os sacrum grow so close together in adults, that they make but one large and solid bone, of the figure of an isosceles triangle, whose basis is tied to the last vertebra of the loins, and the upper part of its sides to the ilia, and its point to the os coccygis. It is concave and smooth on its fore-side, but convex and unequal on its back-side. It hath five holes on each side, but the nerves pass only through the five on its fore-side. Its acute processes or spines are shorter and less than those of the loins, and the lower is always shorter than the upper. The os coccygis is joined to the extremity of the os sacrum; it is composed of three or four bones, of which the lower is still less than the upper till the last ends in a small cartilage: it resembles a little tail turned inwards: its use is to sustain the straight gut; it yields to the pressure of the fœtus in women in travail, and midwives use to thrust it backwards, but sometimes rudely and violently, which is the occasion of great pain, and of several bad effects. From what has been said, it is easy to understand how the motion of the back is performed: though each particular vertebra has but a very small motion, yet the motion of all is very considerable. We have said, that the head moves only backwards and forwards upon the first vertebra, and semicircularly upon the second. The small protuberance which we have remarked in the bone of the hind head, falling upon another in the first vertebra, stops the motion of the head backwards, that it compresses not the spinal marrow; and, when the chin touches the sternum, it can move no farther forwards. The oblique or semi-circular motions are limited by the ligament which ties the process of the second vertebra to the head, and by those which tie the first to the second vertebra. The motion of the other

vertebræ of the neck is not so manifest; yet it is greater than that of the vertebræ of the back, because their acute processes are short and straight, and the cartilages which are between their bodies thicker. The twelve vertebræ of the back have the least motion of any, because their cartilages are thin, their acute processes are long, and very near to one another; and they are fixed to the ribs, which neither move forwards nor backwards. But the greatest motion of the back is performed by the vertebræ of the loins, because their cartilages are thicker, and their acute processes are at a greater distance from one another; for, the thicker the cartilages are, the more we may bend our body forwards; and, the greater distance there is betwixt the acute processes, the more we may bend ourselves backwards. This is the structure and motion of the vertebræ, when they are in their natural position; but we find them also in several persons several ways distorted. If the vertebræ of the back stick out, such as have this deformity are said to be bunch-backed; and in such the cartilages which are between the vertebræ are very thin and hard forwards, but considerably thick backwards, where the oblique processes of the superior and inferior vertebræ are at a considerable distance from one another, which distance fills up with a viscous substance. This inequality of the thickness of the cartilages happens either by a relaxation or weakness of the ligaments and muscles, which are fastened to the back-side of the vertebræ: in which case their antagonists, finding no opposition, remain in a continual contraction, and consequently there can be no motion in these vertebræ. If this deformity has been from the womb, then, the bones being at that time soft and tender, the bodies of the vertebræ partake of the same inequality as the cartilages. If the bunch be towards one shoulder, for example, towards the right, then the cartilages on that side are very thick, but thin and dry on the other side; on the left side the oblique apophyses come close together, but on the right there is a considerable distance between them; and the ligaments and muscles are greatly extended on the right side, but those on the left are much contracted. If the vertebræ are distorted inwards, all things have a different face; the cartilages, and sometimes the vertebræ, are very thick forwards, but very thin and hard backwards; the acute and oblique processes are very close to one another, and the ligaments upon the body of the vertebræ are greatly relaxed, but the muscles and ligaments which tie the processes together are very much contracted. These distortions seldom happen in the vertebræ of the loins; but such as are so miserable have little or no motion of their back.

VERTEBRALES, in anatomy, a pair of muscles, whose office is to stretch out all the vertebræ of the neck.

VERTEX, in anatomy, denotes the crown of the head, or the uppermost part, situated between the sinciput and the occiput.

Hence vertex is also used, figuratively, for the top of other things: thus the vertex of a cone, pyramid, &c. is the top of any one of these figures. See the article **CONE**, &c.

VERTEX of a Glass, in optics, the same with the pole thereof.

VERTEX, in astronomy, is also used for the point of heaven perpendicularly over our heads, properly called the zenith. See **ZENITH**.

Path of the VERTEX, the circle described by the vertical point during one revolution of the earth about its axis.

VERTICAL CIRCLE, in astronomy, a great circle of the sphere, passing through the zenith and nadir, and cutting the horizon at right angles: it is otherwise called azimuth. See **AZIMUTH**.

Prime VERTICAL, is that vertical circle or azimuth which passes through the poles of the meridian; or which is perpendicular to the meridian, and passes through the equinoctial points.

VERTICAL of the Sun, is the vertical which passes through the center of the sun at any moment of time.

VERTICAL PLANE, in perspective, is a plane perpendicular to the geometrical plane, passing through

the eye, and cutting the perspective plane at right-angles.

VERTICAL PLANE, in conics, is a plane passing thro' the vertex of the cone, and parallel to any conic section. See **PLANE**.

VERTICAL LINE, in conics, is a right line drawn on the vertical plane, and passing through the vertex of the cones.

VERTICAL DIAL, is a sun-dial drawn on the plane of a vertical circle, or perpendicular to the horizon.

VERTICAL POINT, in astronomy, the same with vertex or zenith.

VERTICILLATE PLANTS, are such as produce their flowers round the joints of the stalks in whorles; these are the same with the labiated or lipped flowers. All the plants producing flowers in this manner, belong to the didynamia class of Linnæus's system, and of the order gymnospermia; such are hyssop, mint, thyme, &c.

VERTICITY, is that property of the load-stone, whereby it turns, or directs itself to some peculiar point. See **MAGNET**.

VERTIGO, in medicine, a disease in which the head seems to turn round.

This, according to Dr. Willis, is a disorder in which visible objects seem continually to turn round, whilst the patients are affected with a perturbation or confusion of the animal spirits in the brain, which hinders their influx into the nerves. Hence it is, that the visive and locomotive faculties often fail to such a degree, that the patient is ready to drop down, and complains of darkness. Etmuller divides it into three kinds; the first of which is a simple vertigo, in which there is only a transient and short continued gyration of objects. The second is a dark vertigo, or scotomia, when the eyes are darkened, or so affected, as if several colours were before them. The third is the vertigo caduca, in which the patient presently falls down.

A vertigo may be produced by every cause which can distend, press, or contract the arteries; such as sudden fear, surprise, ebriety, and voracity, by which the regular influx and reflux of the animal spirits into the optic nerves and retina are prevented. Sometimes, also, it may be produced by an acid, or any peccant humour, lodged in the stomach, and vellicating its nerves, which communicate with the retina; for which reason the hypochondriac and hysteric passions may produce a vertigo.

With respect to the cure, the regimen in general, ought to be the same with that in the apoplexy or epilepsy. If the patient is plethoric, a due quantity of blood is to be taken away; and if a nausea, loss of appetite, or any other disorder of the stomach remain, an emetic is to be prescribed; then cathartics and specifics are to be ordered. According to Mayerne, calamus aromaticus, in whatever form, is good for a vertigo, and esteemed a secret for that disorder. The same author informs us, that a German physician cured a great many of vertigoes, by pills made of sugar of lead and cypress-turpentine; four or five grains of which were to be taken for a dose, and their use persisted in for some days. Glisson, as Bates informs us, after all other medicines had failed, was cured of a severe vertigo, of three weeks continuance, by shaving his head, and applying to it a plaster of the flowers of sulphur and whites of eggs. Some order a caustic, or seton, to be applied to the back part of the neck; a caustery to the bregma, and Bates's epileptic electuary, or Fuller's Peruvian epileptic electuary, to be used internally.

Willis informs us, that after he had in vain tried all other medicines, he, with success, prescribed the following powder: take of the powder of the roots of male piony, two ounces; of the flowers of male piony, one ounce; of peacock's dung, of the whitest kind, half a pound; and of white sugar, two ounces: reduce to a powder, the dose of which is to be about the quantity of a spoonful twice a day, drinking after it a draught of a decoction of sage and rosemary, impregnated with coffee.

Heister

Heister orders camphorated spirit of wine alone, or mixed with spirit of hartshorn, to be applied to the top of the head and temples. And when the disorder proceeds from crudities in the stomach, he advises to prepare and dissolve them by neutral salts, that they may be afterwards evacuated by an emetic, or purge. After this, the patient should use stomachics and cephalics; as also a moderate quantity of wine at meals, which should be sparing. Pyrmont-water is also said to be excellent in this case.

VERU-MONTANUM, in anatomy, a kind of little valve, in the place wherein the ejaculatory ducts enter the urethra.

Its use is to prevent the urine, in passing the urethra, from getting in at these ducts, and so mixing with the semen.

VERY LORD and VERY TENANT, are those that are immediate lord and tenant to one another.

VESICA, in anatomy, a bladder, a membranous or skinny part in which any humour is contained. See BLADDER.

VESICATORY, *Vesicatorium*, an external medicine, serving to raise a blister; whence, also, it is itself, tho' improperly, called a blister.

Vesicatories are unguents, cataplasms, or plasters, made of sharp irritating medicines, which have a faculty of drawing the humours from within, outwards, inflaming and ulcerating the skin, and raising vesicæ, or bladders, whence their denomination vesicatory.

We have vesicatories made of cantharides, euphorbium, figs, sublimate of mercury, lapis infernalis, mustard, anacardium, squills, briony, vinegar, pepper, leaven, which are incorporated and made up with honey, gums, resins, &c. to bring them to the consistence required.

VESICULA, VESICLE, a diminutive of *vesica*; signifying a little bladder.

The lungs consist of *vesiculæ*. or lobules of *vesiculæ*, admitting air from the bronchiæ; and not only air, but also dust, &c.

There are several parts in the body which bear this appellation; as,

VESICULA *Fellis*, *cistula fellis*, or the gall bladder; which is an oblong membranous vessel, not unlike a pear both in form and size; and is situated in the hollow part of the liver.

It adheres to the liver, not only by its vessels, which it receives from it, but likewise by its membranes, of which, the external is common to both. The lower part, which hangs out of the liver, rests on the pylorus of the stomach.

Its trunks, or membranes, are usually reckoned five; an outer, or common one, from the peritonæum; an inner one, on that side which adheres to the liver from the capsula of the porta, and of the porus bilarius. And three proper ones: the first of which is vasculous; the second, muscular; and third, glandulous.

But Dr. Drake, viewing a piece of dried gall-bladder with a microscope, found but little reason for this accurate distinction; the several orders of fibres of the several coats, appearing to be no other than an infinite perplexity of vessels diversly ramified.

The gall-bladder is usually distinguished into the fundus, which is the widest part; and collum, or neck, which is the narrowest.

The neck of the *vesicula fellis* being prolonged, terminates in a duct, called *meatus cysticus*, or *bilarius*; which, at about two inches distance from the gall bladder, is joined to the *meatus hepaticus*; these, together, form the *ductus communis*.

The use of the gall-bladder, is to receive the bile, after its being secreted in the glands of the liver; and to discharge it by the common duct into the duodenum.

The bile found in this vessel is of a brighter yellow, a greater consistence, and is also more bitter and acrimonious than that in the *porus bilarius*.

VESPA, the wasp, in zoology. See the article WASP.

VESPER, or HESPER, in astronomy. See the article HESPER.

VESPER, in the church of Rome, denote the afternoon service, answering, in some measure, to the evening prayers of the church of England.

Sicilian VESPER, is a famous æra in the French history, signifying a general massacre of all the French in Sicily, in the year 1282; to which the first toll that called to vespers was the signal.

Some will have it to have happened on Easter-eve; others, on the day of the Annunciation. It was raised by one Prochites, a cordelier, at the time when Charles of Anjou, count of Provence, was king of Naples and Sicily: — The women with child by French-men were not spared.

After the like manner, we say, the Mattins of Moscow, speaking of the Muscovites assassinating their prince Demetrius, and all the Poles, his adherents, at Moscow, the twenty-seventh of May, 1600, under the conduct of their duke Choutsky, at six o'clock in the morning.

VESPERTILIO, the bat, in zoology, a genus of quadrupeds of the order of the *feræ*, the characters of which are these: the fore-teeth in the upper jaw are six in number, acute, and distant from each other; the fore-teeth of the lower jaw are also six, and acute, but contiguous: the canine teeth are two both above and below, on each side: the feet have each five toes; and the fore-feet have the toes connected by a membrane, and expanded into a sort of wings, whereby it flies; whence this animal has been generally, but with the utmost impropriety, ranged among the birds.

The common bat is about the bigness of a mouse, and very much resembles it in shape and colour. There are several other species of this creature, some with, and others without, a tail.

VESPERTILIONUM ALÆ, bats-wings, in anatomy, a name given to the two broad ligaments which connect the bottom of the uterus to the bones of the ilium. See the article UTERUS.

VESSEL, *Vas*, denotes in general any thing for holding liquors; such are our domestic cups, pots, &c. as also the retorts, matrasles, crucibles, &c. of the chemists. See CHEMICAL Laboratory.

In anatomy, all the parts which contain or convey a fluid, are called vessels; as the veins, arteries, lymphatics, &c. See VEIN, ARTERY, &c.

Some also extend the word vessel to the nerves, as supposing them the conduits of the animal spirits. See NERVES, and ANIMAL SPIRITS.

VESSEL, in navigation, a general name for all sorts of ships. See the article SHIP.

VESTALIA, in Roman antiquity, a festival celebrated in honour of the goddess Vesta, on the fifth of the ides of June; that is, on the ninth of that month.

On that day, banquets were made before the houses; and meats were sent to the vestals, to be offered by them to the goddess.

The asses that turned the mills for grinding corn, were, on this occasion, led about the city, crowned with flowers, and chaplets formed of pieces of bread; and the mill-stones were likewise decked with garlands and crowns.

The vestalia had their names from that of their goddess Vesta, from the Greeks called *ἑστία*, fire, or hearth; whence Cicero derives the Latin name. Accordingly, the poets frequently use Vesta, for fire, or flame; as they do Jupiter for air, Ceres for corn, &c.

VESTALS, in church history, priestesses of the goddess Vesta.

The institution of this religious order is ascribed to king Numa, who, having built a temple to Vesta, in which a perpetual fire was to be kept up, committed the care of supplying and preserving it to four vestals, whose names were Gegania, Verenia, Canuleia, and Tarpeia. Afterwards Tarquin the elder added two more to them; and it does not appear, that their number ever exceeded six, among whom one was superior to the rest, and called *Vestalis maxima*.

The vestals were chosen from six to ten years of age, beyond which age none was admitted among them. They were obliged to strict continence for thirty years, the

the ten first of which were employed in learning the ceremonies of religion, the next ten in the performance of them, and the ten last in teaching them to the younger vestals. After this, they were permitted to lay aside their ornaments, quit their office as priestesses, and marry. But, as these marriages were observed not to be very happy, few of them left their old profession, even after the time of their ministry was expired. And they found themselves well compensated for the restraints of their condition, by the honours that were annexed to it. When they appeared in public, they were attended by Lictors, as the kings and consuls were. If they accidentally met a criminal going to execution, he was immediately pardoned. They had the precedence wherever they came, and seats of distinction provided for them at the shews of the Circus. Nay, at last, they had a right of being carried to the Temple of Jupiter in a chariot, which was an honour paid only to those of the imperial family; and they were buried within the city, which was a privilege allowed to none but the greatest personages of the empire.

But, as the honours done them were great, so their faults were not suffered to go unpunished. The least levity in them, or the smallest neglect in their office was tried by the Pontifices, and at their command punished with severity. That punishment especially, which was inflicted on them for prostituting their honour, had something in it inexpressibly terrible. The criminal was sentenced to death. On the day of execution, the pontifex maximus stripped her of her ornaments, and she was clothed in a mourning habit. She was carried in a litter, swathed so tight as to be deprived of the use of her voice. Her friends and relations walked before her in tears; and the procession passed cross the Forum, and thence through the Porta Collina, to the place of her punishment. A little vault was dug in the earth, with a lamp burning in it. The vestal was let down into this vault, the entrance of which was bricked up, and covered with earth. And here she was left buried alive.

To suffer the sacred fire to go out, was an unpardonable neglect. It was a law, *Virgines vestales in urbe custodiunto ignem foci publici sempiternum*. And Festus tells us, that when a vestal suffered it to go out, she was punished with whipping, and treated as a slave. The whole city was in a consternation at the accident, and a fresh fire was kindled in the temple of Vesta, with many purifications. This new fire was kindled either by rubbing two pieces of wood one against the other, or by means of a burning-glass, which collecting the pure rays of the sun upon some combustible matter, set it in a flame.

The habit of the vestal virgins consisted of an head-dress, called infula, which sat close to their heads, and from whence hung certain laces called vittæ; a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBLE, *Vestibulum*, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the stair-case. Vestibles, intended for magnificence, are usually between the court and the garden.

The Romans had vestibles at the entrance of their houses, for sheltering those persons who were obliged to stand at the door; and we have now vestibles of a like kind in many old churches, houses, &c. usually called porches.

The term vestibule is sometimes also used for a little anti-chamber, before the entrance of an ordinary apartment.

VESTIBLE of the Ear, in anatomy, a cavity forming the middle part of the labyrinth of the ear.

VESTIGIA, a Latin term frequently used, by English writers, for the traces or footsteps which any thing has left behind it.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; and also a meeting at such place, consisting of the minister, church-wardens, and chief men of most parishes, who make a parish vestry or meeting. By custom there are select vestries, being a certain number of persons chosen to have the govern-

ment of the parish, make rates, and take the accounts of church-wardens, &c. And it is here to be observed, that when any rates are made, the parishioners must have notice of a vestry held for that purpose; in which case all that are absent shall be included by a majority of the parishioners present, who in construction of law are the whole parish. Vestries of parishes are to be consulted by parish-officers; and if a parishioner, who has a right to be present and vote at a vestry, be shut out of the vestry-room, action of the case lies.

VESTRY-MEN, a select number of the principal persons of every parish within the city of London, and elsewhere; who yearly choose parish-officers, and take care of its concerns.

They are thus called, because they usually meet in the vestry of the church.

VESTRY-CLERK, an officer who keeps the parish accounts.

VETCH, *Vicia*, in botany, a genus of plants, the flower of which is of the butterfly kind; the standard is oval, broad at the tail, indented at the point, and the borders are reflexed; the two wings are shorter than the standard; the keel is shorter than the wings; the tail is oblong. It has ten stamina, nine joined and one separated, terminated by erect summits, and a linear compressed germen, supporting a slender style, crowned by an obtuse stigma, which is bearded on the under side. The germen afterwards turns to a long pod with one cell opening with two valves, ending with an acute point, containing several roundish seeds.

Mr. Miller has enumerated five sorts of vetches, and also says there are many more species of this genus, some of which grow naturally in England; but as they are rarely cultivated, except in botanic gardens for the sake of variety, they are omitted, as they are plants of little use or beauty.

Some sorts of this plant, the seeds of which ripen in autumn, grow naturally in most parts of England, in shady places among bushes, and by the sides of woods. The roots of these are perennial; but their stalks are annual, weak, and grow to so great a length (for they will climb up to the height of six or eight feet wherever the tendrils which proceed from the end of their leaves can lay hold of boughs, branches, or the side of a hedge, to support them,) that they are hardly fit to be cultivated in the field, though some writers have recommended them for this purpose; for as they cannot be supported there, they will trail so much upon the ground, that they will be apt to rot: nor do their shoots, which are less succulent than those of the vetch commonly raised, grow to a sufficient height to be cut for use till late in the spring, when there is little want of green food for cattle.

Mr. Miller, after sowing for many years the common vetch or tare, which is much cultivated in the fields for fodder, seems to think that which has black seeds, a distinct species from the white: for he has never found either of them vary. Both these are annual, and perish soon after they have perfected their seed. Their stalks are angular, streaked and hairy: they are weak, and want support, and generally trail upon the ground when they do not find any thing to fasten themselves to. Their leaves are composed of several pair of blunt lobes, and are terminated by tendrils. The flowers, which are pretty large, proceed from the wings of the stalk, and sit very close to the base of the foot-stalks of the leaves. Two of these flowers generally spring from the same joint: those of the black seeded sort are purple, and those of the white seeded are white. They appear in June and July, and are succeeded by erect pods containing three or four round seeds in each, which ripen in August and September.

The white vetch is rather the more succulent plant of the two, and therefore it is best for fodder: but many are unwilling to cultivate this sort, because their seeds, being white, are much sooner discovered by rooks and other birds, than those of the black, which bear a nearer resemblance to the colour of the ground. This objection may, however, be easily removed, by sowing them in drills, and then covering them carefully, instead of the usual method of scattering them with a broad-cast, and plowing them in lightly.

The

The small black-seeded vetch, which some call rath-ripe, and others pebble, goar, or summer vetch, is much tenderer than either of the former, and therefore less cultivated. This must always be sown in the spring: whereas the others may be sown in spring or autumn.

But another species of vetch, viz. the Siberian, hardly known to the generality of farmers in this country, bids fair to become, perhaps, the most useful of all for fodder; for its stalks grow to a great length, and are well furnished with leaves, which do not decay in autumn, like those of the other sorts, but continue green all the winter, in defiance of the hardest frost: so that in February and March, when there often is a scarcity of green fodder for ewes and lambs, this may be of singular service, especially if these plants are supported from trailing upon the ground. Their flowers, which appear in July, are of a light blue colour.

This, like our common vetch, may be sown in the spring, or in autumn; and when the plants are come up, they will not require any other culture than keeping them clear from weeds; a work which, if the seeds are sown thin in rows four feet asunder, as Mr. Miller rightly advises, may be easily done with the Dutch hoe, while they are young, and afterwards with the hoeing plough. By this thin sowing, the stalks of these vetches, which send out many branches, and extend very far, will be kept from matting so closely together as to rot each other by excluding the air; and by earthing up their stems in the same manner as should be done for peas and beans, they will be greatly strengthened, their leaves will grow the larger and more succulent, and they will consequently yield an increased quantity of fodder. The repeating of this as often as it may be found necessary to destroy the weeds in summer, which may be done at a very small expence, and is particularly proper when the growth is intended for the green food of cattle, will be attended with the farther important advantage of preparing the ground thoroughly for whatever other crop may afterwards be put upon it.

As the plants of this kind of vetch will not be in danger of being hurt by frost, they should not be cut till the spring, when the best way will be to take them as they may be wanted, green, for the feeding of ewes: but some of them should be left untouched, for seeds; for if those which are cut do shoot out again, they will flower so late in summer, that their seeds will not ripen, unless the autumn proves very warm. A better way will therefore be to sow a proper quantity of seeds for this purpose in a separate spot of ground: because, when the other is cut, the ground may be plowed for other crops; and if the seasons should be so mild as to produce a sufficiency of green food independent of this, the vetches may be plowed into the ground, to which they will be an excellent dressing for other crops.

Mr. Miller, who has a high opinion of this sort of vetch, and whose recommendation of it ought to have very great weight, is now beginning to try it in the field, where he has not yet had experience of its culture: but the experiments which he has made with it for six years past, on small patches of it sown in gardens, in different situations, have fully answered his expectation: for he has found these plants continue in great verdure in all those places, when most of the perennial plants in the same situation have suffered greatly by the frost, and could have cut from only eight of them as much fodder as would have been equivalent to half a truss of clover.

Vetches are generally sown either in autumn, or early in the spring: but the best time, in this country, is toward the beginning of August; because the rains which usually fall about that season will bring them up in a short time, and the plants will get strength before winter, and be fit to cut for the food of cattle early in the spring, when green fodder is most wanted: and if they are designed for seed only, these early sown vetches will come early into flower, and their seeds will ripen early, so that they may be cut and stacked in good weather, which is a great advantage; for those which ripen late, are often stacked or housed wet, and then their seeds frequently sprout in the mow, and are spoiled.

Vetches will do well in almost any ground; not excepting even such as can scarcely produce any other plant. The common method of sowing them is in broadcast, ploughing them lightly in, as was observed before; and the usual allowance is two bushels of seed for an acre of land, tho' some sow two bushels and an half. Either of these practices may do well enough for those vetches which are intended to be cut for fodder in the spring; but when they are sown with a design to let them stand for seed, it will certainly be much better to sow them in drills, in the same manner as is practised for peas; and in this case less than half of the abovementioned quantity of seed will be sufficient: for the rows should be at least three feet asunder, that the hoe-plough may have room to go between them, to destroy the weeds, and earth up the plants, which, when thus managed, will produce a much greater crop, and ripen better and earlier, than in the common way. These drills should be of about the same depth as for peas, and the seeds should be scattered at about the same distance in the drills, in which they should be carefully covered over as soon as they are sown; for otherwise the rooks will discover them; and when those voracious creatures once find the rows, they will speedily destroy them intirely, if they are not carefully watched. The preventing of this is another advantage which attends the sowing of vetches early in autumn, rather than in the spring: because there is more food for rooks and pigeons in the open field in the former of these seasons, and the plants will then appear much sooner above ground. Toward the end of October, by which time the plants will have acquired considerable strength, the horse-hoe should begin to work between the rows, provided the weather be dry: and in doing this, particular care should be taken to lay the earth up as high to the stems of the plants as can possibly be, without covering their tops. This will help to secure them against frost, and clear the ground of weeds at least till March, when the plants should be earthed up a second time, and the intermediate spaces between their rows be cleaned again, in the same manner as before. This will make them grow so vigorously, that they will meet and cover those spaces in a little time: whereas those sown in the spring will not grow to half this size, and will be very late in flowering.

When vetches are intended only for fodder, of which they generally afford two good crops in the year, in hot countries, or when the farmer designs them for plowing in, by way of manure, they need not be sown in drills, or husbanded in the manner directed: the common broadcast way will then do well enough; but still it is most adviseable, in either case, to sow them early in autumn; because, in the first place, they will produce the desired green fodder much earlier in the spring; and in the second, they will be fit to plow in much sooner the following year, and thereby have time properly to meliorate the land, and prepare it to receive the ensuing crop, which they are generally allowed to do even more effectually than peas. Stiff clays are peculiarly benefited by this dressing: but it surely is bad husbandry to sow vetches for green fodder, where lucerne will thrive; because this last will yield greater plenty of still more nourishing food.

In some countries, especially abroad, they mix oats with their tares or vetches, an equal quantity of each, and sow them in February. The vetch, supported in some measure by the oat, grows the higher for it: and, about the middle of May, this mixture is mowed, and given to horses and other cattle, which it fattens greatly. Mr. Mortimer likewise thinks it a good way to sow horse-beans and tares together: their seeds are easily parted with a riddle: and another observation in which he agrees with the *Maisons Rustiques*, is, that more vetches should not be sown at any one time, than can be covered the same day, because the dew is apt to spoil them: consequently they should not be sown till two or three hours after the rising of the sun; by which time the moisture will be exhaled from off the surface of the earth. But though their seeds cannot bear dampness, which would soon rot them, their plants, especially in sandy land, often perish in dry years, for want of water. To make

them flourish well, they require a shower of rain every ten or twelve days. One plowing to turn in the stubble of the preceding crop, and another at the time of sowing, are sufficient for this plant: but those who give only one plowing, which is when they sow, and afterwards harrow in the seed, neither have, nor can expect, an equally good return.

When vetches are cultivated for their seeds, they should be cut soon after the pods turn brown, and stacked as soon as they are dry: for if they are suffered to lie out in the field, till they receive wet, and there then comes a hot day, most of the pods will burst, unless they happen to have been blighted; in which case they will not open so easily. Their haulm, when dry, and threshed, is esteemed good food for cattle, and some say that their seeds are as good for horses, as beans; which, if true, should render them the more valuable, because these will grow on the lightest sandy land, where beans will not thrive; and may therefore, as Mr. Miller observes, be a good improvement to some counties in England where they do not even attempt to cultivate the bean. About three loads from an acre are reckoned a good crop.

Vetches, when threshed out, will be as good for sowing at the end of five or six years, as at first, if care be taken to turn them in a heap from time to time. Mr. Mortimer cautions the husbandman to lay them by themselves in some convenient place, separate from his other corn, because they will otherwise be apt to foul it.

It is commonly said, that the farmer cannot sow any thing more profitable than vetches; for that, besides enriching the land, a load of them will go farther than two loads of hay: but Mr. Lisle has a calculation tending to prove, that an acre of broad clover is worth twenty shillings a year more than an acre of any vetches, and that the clover should therefore be preferred, wherever the ground will bear it well.

VETERAN, in the Roman militia, a soldier who was grown old in the service; or who had made a certain number of campaigns; and on that account was entitled to certain benefits and privileges.

Twenty years service were sufficient to entitle a man to the benefits of a veteran. These privileges consisted in being absolved from the military oath; in being exempted from all the functions of a soldier; and in enjoying a certain salary, or appointment, &c.

In France, the term veteran is still retained to such officers as have held their posts 20 years; and who enjoy certain of the honours and privileges affixed thereto, even after they have laid them down.

A veteran counsellor has a voice and seat at audiences, tho' not at processes by writing. A veteran secretary of the king acquires the privileges, &c. of nobility, to himself and his children.

VIA-LACTEA, in astronomy, the milky-way, or galaxy. See GALAXY.

VIA-SOLIS, the Sun's Way, in astronomy, is used, among some astronomers, for the ecliptic line, so called, because the sun never goes out of it. See the article ECLIPTIC.

VIAE PRIMÆ, first passages, among physicians, are the œsophagus, stomach, and guts; including the whole length of the alimentary duct, or canal, from the mouth to the sphincter ani.

VIALES, in mythology, a name given among the Romans to the gods who had the care and guard of the road and highways.

The dii viales, according to Labeo, were of the number of those gods called dii animales, who were supposed to be the souls of men changed into gods; and were of two kinds, viz. the viales and penates.

VIATICUM, in the church of Rome, an appellation given to the eucharist, when administered to persons at the point of death.

VIATOR, in antiquity, an officer of justice among the Romans.

The term, originally, had no other signification than that of a public messenger, or servant, sent to advertise the senators and magistrates when assemblies were to be held, where their presence was required.

Hence, because, in the first ages of that empire, the Roman magistrates lived mostly at their country-houses; these officers being obliged to be frequently upon the road, were called *viatores*, travellers; from *via*, highway.

In process of time, the name viator became common to all officers of the magistrates, lictors, accensi, scribes, statores, and cryers; either by reason these names and offices were confounded in one: or because viator was a general name, and the rest particular ones, specifying the particular functions they discharged, as A. Gellius seems to insinuate, when he says, that member of the company of viatores, who binds a criminal condemned to be whipped, was called lictor.

Be this as it will, the names lictor and viator are often used indiscriminately for each other; and we as often meet with "Sent to seek, or advertise him by a lictor, as by a viator."

None but the consuls, prætors, tribunes, and ædiles, had a right to have viatores. — They were not to be Roman citizens, and yet they were required to be free.

VIBEX, is sometimes used, by physicians, for a black and blue spot in the skin, occasioned by an afflux or extravasation of blood.

VIBRATION, in mechanics, a regular, reciprocal motion of a body, as a pendulum, &c. which, being freely suspended, swings or oscillates, first this way, then that. See PENDULUM.

VIBRATION is also used in physics, &c. and for divers other regular alternate motions. — Sensation is supposed to be performed, by means of the vibratory motion of the nerves, begun by external objects, and propagated to the brain.

The several sorts and rays of light, Sir Isaac Newton conceives to make vibrations of several bignesses; which according to those magnitudes, excite sensations of several colours; much after the same manner as vibrations of air, according to their several magnitudes, excite sensations of several sounds.

Heat, according to the same author, is only an accident of light, occasioned by the rays putting a fine, subtle ethereal medium, which pervades all bodies, into a vibrative motion, which gives us that sensation.

From the vibrations, or pulses of the same medium, he accounts for the alternate fits of easy reflection, and easy transmission of the rays.

In the Philosophical Transactions it is observed, that the butterfly, into which the silk-worm is transformed, makes 130 vibrations, or motions of its wings, in one coition.

VIBURNUM, the wayfaring, or pliant mealy-tree, in botany, a tree, the flower of which has a small permanent empalement, which is cut into five parts; it has one bell-shaped petal, cut at the brim into five obtuse segments, which are reflexed; it has five awl-shaped stamina the length of the petal, terminated by roundish summits, and a roundish germen, situated under the flower, having no style, but the place is occupied by a roundish gland, and crowned by three obtuse stigmas. The germen afterwards turns to a compressed fruit with one cell, inclosing one hard seed.

There are eight species of this plant, the first of which grows naturally in many parts of Europe, and is the common viburnum or lantana of the old botanists. The leaves are heart-shaped, much veined, irregularly sawed on their edges, and are very woolly on their under side. The stalks are woody, and rise twelve or fourteen feet high, sending out strong ligneous branches, which are covered with a light coloured bark; these are terminated by umbels of white flowers, whose summits are red, and are succeeded by roundish compressed berries, which turn first to a bright red colour, and are black when ripe, inclosing one seed of the same shape.

There is a variety of this with variegated leaves, which is preserved in some of the gardens near London; but when the plants are removed into good ground, and are vigorous, their leaves become plain.

The second sort grows naturally in most parts of North America, where it is commonly called black haw.

This

This rises with a woody stalk ten or twelve feet high, covered with a brown bark, and sends out branches from the side; these, when young, are covered with a purple smooth bark, and are garnished with oval smooth leaves, which are slightly sawed on their edges, and stand upon short slender footstalks, sometimes opposite, and at others without order. The flowers are disposed in small umbels, which come out from the side and at the end of the branches; they are white, and smaller than those of the common viburnum; these are succeeded by berries, which ripen in autumn.

The third sort grows naturally in North America. The stalks of this sort are soft and pithy, and branch out greatly from the bottom upward. The bark is of a grey colour; the leaves are roundish, oval, strongly veined, and sawed on their edges, of a light green colour, and placed opposite upon pretty long foot-stalks. The flowers are disposed in a corymbus at the end of the branches, which are white, and almost as large as those of the common sort; these appear the latter end of June, but are seldom succeeded by seeds in England.

The fourth sort is the laurustinus with small leaves, which are hairy on their under side; this plant is so well known as to need no description, but as it is frequently confounded with the next, it may be necessary to point out its difference. The leaves of this are seldom more than two inches and a half long, and one and a quarter broad; they are rounded at their base, but end in acute points; they are veined and hairy on their under-side, and are not of so lucid a green colour on their upper-side. The umbels of flowers are smaller, and appear in autumn, continuing all the winter, and the plants are much hardier.

The fifth sort is commonly known in the nursery-gardens by the title of shining leaved laurustinus. The stalks of this rise higher, the branches are much stronger than those of the former sort. The bark is smoother, and turns of a purplish colour; the leaves are larger, of a thicker consistence, and of a lucid green colour; the umbels are much larger, and so are the flowers: these seldom appear till the spring, and when the winters are sharp, the flowers are killed, so never open unless they are sheltered. The plants of this sort were formerly kept in tubs, and housed in winter, and, when they were so treated, made a fine appearance early in the spring, and in very mild seasons the plants in the open air do the same.

There is a variety of this with variegated leaves, which makes as good a figure as any of the striped plants which are preserved in gardens.

The sixth sort is a native of North America, where it rises to the height of ten or twelve feet, sending out branches on every side their whole length; these have a smooth purplish bark, garnished with oval entire leaves, of a thick consistence, and of a lucid green; they stand opposite. The flowers are produced in umbels at the end of the branches; they are white, and not unlike the flowers of laurustinus; these appear in July, and are succeeded by berries, which seldom ripen in England.

There seems to be two sorts of this in the gardens, one of which comes from the more northern parts of America, and sheds its leaves in winter; the other, which grows in Carolina and Virginia, is an ever-green; but both are so much alike in summer, as scarce to be distinguished.

The seventh sort is the common marsh-elder, which grows naturally in marshy grounds, and on the sides of rivers in many parts of England, so is not often kept in gardens; it is called by some of the nursery-gardeners guelder-rose with flat flowers, to distinguish it from the other, whose flowers are globular. The marsh-elder is the original species, and the guelder-rose is a variety which accidentally arose from it. The former has a border of male flowers, which are large, and the middle of the umbel is composed of hermaphrodite flowers, which are succeeded by oval red berries; the latter has all male flowers, of the same size and shape with those of the border of the first, so that they swell out into a round figure, which has occasioned some country people giving it the name of snow-ball tree. This sort is

cultivated in gardens for the beauty of its flowers, which make a fine appearance during their continuance.

It will rise to the height of eighteen or twenty feet, if it is permitted to stand. The stem becomes large, woody, and hard; the branches come out opposite, and are apt to grow irregular; they have a grey bark. The leaves are placed opposite; they are divided into three or four lobes, somewhat like those of the maple, jagged on their edges, and of a light green colour. The flowers come out at the end of the branches: those of the first in large umbels, and those of the second in a corymbus; they are very white, and appear the beginning of June; those of the first have oval berries succeeding the hermaphrodite flowers, which turn of a scarlet colour when ripe, but the other, having only male flowers, are barren.

The eighth sort grows naturally in Carolina and some other parts of North America; this rises with a shrubby stalk eight or ten feet high, sending out many branches, which are covered with a smooth purple bark, garnished with heart-shaped oval leaves, ending in acute points; they are deeply sawed on their edges, have many strong veins, and stand upon very long slender foot-stalks opposite. The flowers are collected into large umbels at the end of the branches; those ranged on the border are male and barren, but the middle is composed of hermaphrodite flowers, which are succeeded by oval berries. The flowers are white, and the berries are red when ripe.

The first sort may be propagated either from seeds, or by laying down the tender branches; but the former method being tedious, is seldom practised, because the seeds seldom grow the first year, unless they are sown in autumn; and as the branches easily put out roots, that is the more expeditious method.

The best time for laying these branches is in autumn, just as the leaves begin to fall; the manner of laying them being the same as for other hardy trees, need not be here repeated. By the succeeding autumn the layers will be rooted, when you may take them off from the old plants, and transplant them into a nursery for two or three years, in which they may be trained up to regular stems and heads, and may afterwards be planted where they are to remain.

The second sort is generally propagated by layers here, because the seeds do not often ripen in England. The young shoots of this take root very freely; the cuttings will also take root, if they are planted in autumn; the seeds, when they are brought to England, always remain in the ground a year, like those of the other sorts, so that the propagating the plants by seeds is a tedious method.

The laurustinuses are propagated by laying down their young branches, which put out roots very freely; so that when they are layed in autumn, they will be well rooted by that time twelve months, when they should be taken off from the old plants, and may either be planted where they are to remain, or into a nursery to grow two years to get strength. The best season to transplant these is at Michaelmas, that they may get new root before winter; for as these plants begin to flower early in winter, it is a plain indication of their growing at that season, so they will more surely succeed than at any other time of the year, though they may be removed in the spring with balls of earth to their roots, provided it is done before they begin to shoot; they may also be removed the latter end of July or the beginning of August, if rain happens at that time; for after they have done shooting, which is soon after Midsummer, they will be in no danger, provided they are not kept out of the ground any time.

These plants may also be propagated by seeds, which should be mixed with earth in autumn, soon after they are ripe; these should be exposed to the open air, and receive the rain in winter, and in the spring they may be sown upon a gentle hot-bed, which will bring up the plants; these should remain in the bed till autumn, and then they may be transplanted and treated in the same way as the layers. I have raised many of these plants from seeds, which I find hardier than those raised by layers.

Some people train up the laurustinus with naked stems to have round heads, but if these are planted in the open air, they will be in more danger of suffering by severe frosts, than those whose branches grow rude from the bottom; for if the frost kills the outer part of the shoots, the stems will be protected, so will soon put out new branches; but where the stems are naked, the frost frequently kills them to the root.

The sixth sort may be propagated in the same way as the laurustinus, and requires the same treatment; it loves a soft loamy soil, and should have a sheltered situation.

The seventh and eighth sorts are easily propagated by layers or cuttings. The common guelder-rose sends out plenty of suckers from the roots, by which it is frequently propagated; but as the plants so raised are very subject to put out suckers, they are not so good as those which come from layers or cuttings. Both these sorts have a moist soil, in which they will make much greater progress, and produce their flowers in greater plenty than on a dry soil.

They are both very hardy, so will thrive in the coldest situations, but not within the spray of the sea. The common guelder-rose is seldom suffered to stand very long in gardens, but I have seen one in an old garden, whose stem was more than two feet and a half round. *Miller's Gard. Dict.*

VICAR, a person appointed as deputy of another; to perform his functions, in his absence, and under his authority.

The pope pretends to be vicar of Jesus Christ on earth.—He has under him a grand-vicar, who is a cardinal, and whose jurisdiction extends over all priests both secular and regular; and even, in many cases, over laymen.

Among the ancient Romans, vicar was a legatus, or lieutenant, sent into the provinces where there was no governor; so that the vicarii were properly the emperor's vicars, not those of governors.

Italy, in the time of the Eastern empire, was governed by two vicarii, the one vicar of Italy, who resided at Milan; the other vicar of the city, who resided at Rome.

Cujas observed, that the word vicar was sometimes, though rarely, attributed to the lieutenant-generals of proconsuls, or governors of Roman provinces.

VICAR, in the canon law, denotes a priest of a parish, the predial tithes of which are impropriated, or appropriated; that is, belong either to a chapter, religious house, &c. or to a layman, who receives them, and only allows the vicar the small tithes, or a convenient salary, anciently called *portia congrua*.

He is thus called, as serving for, or in lieu of a rector, who would be entitled to the great tithes.

These vicars were anciently called *perpetui vicarii*, because not appointed by the impropriator, and licensed by the bishop to read service; but presented by the patron, and canonical institution given them by the hands of the ordinary; and so having constant succession, or corporations, and never dying.

The canonists mention four species of vicars; some perpetual; others appointed for a certain time, and on some special occasion, called *mercenarii*; others called *speciales*, appointed not for the whole cure, but for some certain place, article, or act: others *generales*, neither perpetual, nor appointed for any certain act, but for all things in the general.

VICAR GENERAL, was a title given by king Henry VIII. to Thomas Cromwell, earl of Essex; with full power to oversee the clergy, and regulate all matters relating to church affairs.

VICE, *Vitium*, in ethics, is ordinarily defined an elective habit, deviating, either in excess, or defect, from the just medium wherein virtue is placed.

It is called a habit, to distinguish it from sin, which is only an act: hence, a sin is looked on, as something transient; and a vice, as something permanent.

Authors distinguish three states of vice: the first *incontinentia*, of incontinence; wherein a person sees, and approves the good, but is hurried to evil by the violence of his passions. The second, *intemperantia*, of intem-

perance; wherein, even the judgment is depraved and perverted.—The third, *feritatis*, of obduracy; wherein the person is totally immersed in vice, without any sense or feeling thereof.

The state of incontinency is considered as infirmity, wherein the person feels the sharpest stings of conscience: that of intemperance, as malice, wherein the remorse is not so lively.—In that of obduracy there is none. See HABIT, VIRTUE, &c.

VICE, in smithery, and other arts employed in metals, &c. is a machine or instrument, serving to hold fast any thing they are at work upon; whether it be to be filed, bent, or riveted, &c. For a particular description of the vice, see the article SMITHERY.

Hand-VICE, is a small kind of vice serving to hold the lesser works in, that require often turning about.

Of these there are two kinds, the broad chapped hand-vice, which is that commonly used; and the square-nosed hand-vice, seldom used but for filing small round work. See SMITHERY.

VICE is also a machine used by the glaziers, to turn, or draw lead into flat rods, with grooves on each side, proper to receive the edges of the glass.

This machine consists of two iron chaps, or cheeks, joined with two cross iron pieces. In the space between the chaps, are two steel wheels, and their spindles, or axes passed through the middle; each of which has its nut, or pinion with teeth, that catch into each other: and to the lowest is fitted a handle, whereby the machine is turned.

There are some of these vices double, and that will draw two leads at once: these have three wheels.—Some glaziers will turn lead of different sizes in the same vice, by changing their cheeks for each size.

With another pair of spindles, whose nuts almost meet, they turn lead for tiers, by the glaziers called bands, which when it comes out of the vice, is almost cut asunder, in two thicknesses, easy to be parted. Before the invention of this vice, which is but a late thing, they used a plane; accordingly, in all the ancient windows, we find the lead planed, and grooved that way.

VICE is also used, in the composition of divers words, to denote the relation of something that comes instead, or in the place of another.

VICE-ADMIRAL, is one of the three principal officers of the royal navy; who commands the second squadron, and has his flag set up in the fore-top of his ship.

VICE-CHAMBERLAIN, called also, in ancient statutes, under-chamberlain, is an officer in the court, next under the lord chamberlain; and who in his absence, has command, and control, of all officers belonging to that part of the household called the chamber above stairs.

VICE-CHANCELLOR of a University, is an eminent member, chose annually, to manage affairs in the absence of the chancellor.

VICE-DOGE, is a counsellor of Venice, who represents the doge, when sick, or absent; that the seignory may never be without a chief.

VICE-ROY, a governor of a kingdom, who commands in the name and stead of a king, with full and sovereign authority.

VICE-VERSA, a Latin phrase, importing on the contrary: thus, as the sun mounts higher and higher above the horizon, the shadows of things decrease; and *vice versa*, as he descends lower, they increase.

VICISSITUDE, the regular succession of one thing after another; as the vicissitude of a day and night, of the seasons, &c.

VICOUNT, in old law books, signifies the same with sheriff.

VICOUNT, or VISCOUNT, is also a degree of nobility next below a count, or earl, and above a baron. See the articles NOBILITY, EARL, &c.

VICOUNTIEL, in law-books, something belonging to, or falling within the sheriff's jurisdiction: thus writs vicountiels are writs triable in the sheriff's court; and there are certain vicountiel rents, of which the sheriff keeps a particular roll, that usually comes under the title of *firma comitatus*.

Also vicountiel jurisdiction, is that which belongs to officers of a county; as sheriff, &c.

VICTIM, *Victima*, denotes a bloody sacrifice offered to some deity, of a living creature, as a man or beast, which is slain to appease his wrath, or obtain some favour.

VICTIMARIUS, in antiquity, a minister or servant of the priest, whose office was to bind the victims, and prepare the water, knife, and other things necessary for the sacrifice.

To the victimarii it also belonged to knock down and kill the victims, in order to which they stood close by the altar naked to the waist, but crowned with laurel; and holding a hatchet or a knife, up, asked the priest leave to strike; saying, Agone? whence they were called agones and cultellarii.

When the victim was killed, they opened it, and after viewing the entrails, took them away, washed the carcase, sprinkled the flour on it, &c. The same victimarii lighted the fire wherein books were condemned to be burnt.

VICTORY, *Victoria*, the overthrow or defeat of an enemy, in war or combat.

VICTUALLING-OFFICE, an office kept on Tower-hill, London, for the furnishing his majesty's navy with victuals.

It is managed by seven commissioners, who have their inferior officers, as secretaries, clerks, &c. besides agents in divers parts of Great Britain, Ireland, &c. See COMMISSIONERS, &c.

VICTUALS, signifies any sustenance, or things necessary to live upon, as meat and provisions; which are to be sold at a reasonable price, assessed by justices, &c. on pain of forfeiting double the value. By the custom of some manors, they choose yearly surveyors of victuals.

VI ET ARMIS, in law, are words made use of in indictments and actions of trespass, to shew the violent commission of any trespass or crime; but in an appeal of death, or where a person is killed with a weapon, these words are not held necessary, because the violence is implied.

VIEW, in law, signifies the particular act of viewers; as where a real action is brought, and the tenant does not certainly know what land it is the defendant requires; then he may pray that the jury may view the same, that is to say, see the land that is claimed. But it is held, that in all cases of viewing, the thing in controversy is only to be shewn to the jurors, and no evidence can be given relating to it on either side: and here if waste be alledged to be done, the view of the house generally is sufficient.

VIEW of frank Pledge, is the office which the sheriff in his county-court, the steward in the leet, or the bailiff in his hundred, performs in looking to the king's peace, and see that every man be in some pledge.

VIGILS, in church-history, are the fasts appointed before certain festivals, in order to prepare the mind for a due observation of the ensuing solemnity.

VIGINTIVIRATE, a tribunal or court among the ancient Romans, first established by Cæsar, consisting of twenty members, three of whom judged of all criminal matters; three others had the inspection of the coins; four others had the inspection of the streets of Rome; and the rest were judges of civil affairs.

VILLAGE, an assemblage of houses, inhabited chiefly by peasants and farmers, and having no market, whereby it is distinguished from a town.

Fleta tells us, that the difference made between a mansion, a village, and a manor, is this, viz. a mansion may consist of one or more houses, but must be of one dwelling-place, and none near it; for if any other houses are contiguous, it is then a village; and a manor consists of several villages, or of one alone.

Where in legal proceedings a place is named generally, it shall be taken for a vill, because as to civil purposes the kingdom was first divided into vills; yet it has been held, that a vill and a parish shall be intended the same.

VILLAIN, or **VILLEIN**, *Villanus*, in our ancient customs, denotes a man of servile and base condition, viz. a bondman or servant: and there were anciently two sorts of bondmen or villains in England; the one term-

ed a villain in gross, who was immediately bound to the person of his lord and his heirs; the other a villain regardant to a manor, he being bound to his lord as a member belonging and annexed to the manor whereof the lord was owner; and he was properly a pure villain, of whom the lord took redemption to marry his daughter, and to make him free; and whom the lord might put out of his lands and tenements, goods, and chattels at his will, and beat and chastise, but not maim him.

VILLENAGE, a kind of ancient tenure, whereby the tenant was bound to do such services as the lord commanded, or such as were fit for villains or bondmen to perform.

VILLI, among botanists, a kind of down like coarse hair, or the grain or shag of plush, with which some trees abound.

VILLOSE, or **VILLOUS**, something abounding with villi, or fibres like coarse hairs: such is one of the coats of the stomach. See STOMACH.

VINCA, periwinkle, in botany, a genus of plants, whose flower is monopetalous and saucer-shaped, with an horizontal limb divided into five obtuse segments; the stamina consists of five very short inflexed filaments, topped with erect, obtuse, membranaceous antheræ; the fruit consists of two erect cylindric husks opening longitudinally with one valve, and contains a number of oblong, cylindric, and furrowed seeds.

A species of this genus, which grows naturally on the island of Madagascar, is exceeding beautiful, and continues in full blossom all the summer, but being tender, requires a stove in this climate for its preservation.

This kind is easily propagated by cuttings in any of the summer months.

The common periwinkle grows wild among hedges, &c. in many parts of England; it has a fibrous root, with slender trailing stalks, furnished with oblong, ever-green leaves; it begins to flower in the spring, and continues a succession of blossoms for a long time.

It is said to be vulnerary, astringent, and febrifuge; and is given to abate all kinds of bleeding: the fresh leaves applied to the swellings of the king's evil, mixed with lint, are accounted by some an excellent remedy to disperse and dissolve them.

VINCULUM, in mathematics, a character in form of a line, or stroke, drawn over a factor, divisor, or dividend, when compounded of several letters or quantities, to connect them, and shew they are to be multiplied, or divided, &c. together by the other term. Thus $d \times a + b - c$ shews that d is to be multiplied into $a + b - c$.

VINDEMIATING, the gathering of the grapes, or other ripe fruits, as the apples, pears, cherries, &c.

VINDEMIATRIX, or **VINDEMIATOR**, a fixed star of the third magnitude in the constellation Virgo. See VIRGO.

VINDICATION, or claiming, in the civil law, an action arising from the property a person has in any thing; or a permission to take or seize a thing, as one's own, out of the hands of a person, whom the law has doomed not to be the true proprietor.

VINE, the name of a shrub of the reptile kind, which is with good reason preferred to all others, both for the sweetness of its fruit, and for the ease with which it repays the labour bestowed on its culture.

It grows as happily in plains as upon hills, and thrives as well in a strong soil, as in that which is loose and open; also in poor as well as in rich land, and in a dry as well as in a moist soil. It alone best endures the intemperature of heat, cold, or stormy weather.

Nevertheless, it is of great importance that the quality of the vine be adapted to the condition of the country: for neither is the culture the same in every soil and climate, nor are all vines of the same kind. It is not easy to say which is the best; experience teaching us, that every country has its own, which is more or less proper for it. A judicious husbandman will however easily find, that vine is proper for the plain, which bears fogs and hoar-frost without being hurt; and for a hill, that which

can bear drought and wind. He will plant in a rich and fertile soil, a slender vine, which does not bear plenty of fruit; in a stiff soil, one that makes strong shoots and is covered with plenty of leaves; and in a loose soil one that makes but few shoots. He will find, that it is not proper to commit to a moist place a vine which bears tender and large grapes; nor to a dry place, a vine of a contrary quality.

The good husbandman will also know, that the nature of the climate is of great consequence; whether it be hot or cold, wet or dry, subject to hail and wind, or calm, clear, or cloudy. Two sorts of vines are fit for a cold and cloudy situation, viz. either one which is early, and ripens its fruit before the winter; or one of firm and hard grapes, which bloom in the midst of fogs, and afterwards mellow with the cold and hoar-frost, as other grapes do with warmth. Where wind and storms are frequent, the vines must take deep root and have hard grapes: where the situation is warm, they may be of more tender and more fruitful kinds. Vines whose grapes rot with rain and constant dews should be planted in dry places; and those in moist, which are hurt by drought. If any vines are planted in places subject to hail, it should be those which have large and strong leaves; because they will shelter the fruit. Where the sky is usually serene and fair, all sorts of vines will grow: and those may be planted to advantage, whose grapes fall quickly off.

Could we have the quality of the soil, the situation of the place, and the state of the weather to our wishes; that soil should be preferred, which is neither too strong nor too loose, but rather inclining to loose; neither poor, nor exceeding rich, but rather fertile. The situation should neither be a plain, nor steep, but yet on a rising ground; it should neither be wet nor dry, yet moderately moistened with dews: it should neither have springs on the surface, nor at some depth in the earth; and yet it should communicate to the vines a moisture which is neither bitter nor salt; for either of these will vitiate the taste of the wine, and give a scurvy rough coat to every plant that grows on such land. The state of the moisture may be known, by dissolving some of the earth in water. The vine does not prosper either in a frozen, or in a scorching hot climate; but it thrives best in a country that is rather warm than cold. It is hurt more by rain, than by dry weather, and prospers better in a dry climate, than where rains are frequent. It delights in gentle and moderate gales, but is greatly damaged by storms.

It is an observation of long standing, that ground which has never been plowed, or had trees growing on it, is the best for a vineyard. All authors agree, that an old vineyard is the worst of any for making a new plantation; because the earth is entangled with the old roots of the vines matted together, poisoned by their decay, and quite exhausted by their long standing. Woodlands may be used, because the roots of common trees and shrubs are easily extirpated. Where there is no unplowed land, the next best is a corn field, free from trees, or where trees have not been planted thick.

The fitness of new ground for the vine may be judged of by the shoots of such shrubs as grow naturally in it: for if they make thriving shoots, which have not a ragged or stunted appearance, the vine will flourish there. Of all soils, a black rich mould is the best for vines. Stones which crumble, or rot as it were, with the weather, being broken, and laid to the roots of the vines, retain a moisture, cool them, and, by that means, are exceeding fit for nourishing them. For the same reason gravel, pebbles, and loose stones are approved of, provided they be mixed with rich mould: but if they are mixed with poor earth, they are bad. Flints are likewise very friendly to vines, if covered with a moderate depth of earth; because, being cold, they retain the moisture, and prevent the roots being parched up in the dog-days. The foot of mountains, which receive the earth washed down from their tops; or vallies, to which additions are made by the settling of rivers, which overflow them, are very proper for vineyards. A chalky bottom is fit for the vine; but clay, not excepting even that which ap-

proaches to marle or potter's clay, is very unfit; as is also coarse hungry sand. On mountains and rising grounds, and on the sides of hills, vines do not easily take firm root; but they yield wine of a lasting and excellent flavour. In moist and level places, vineyards are exceeding strong; but they produce wine of a weak flat taste, which does not keep long.

It may be established as a general rule, to plant vineyards in cold countries so as to face the south, and in warm countries facing the east, unless they are subject to storms from that quarter, in which case it is better that they face the north. In exceeding hot countries, such for example as Egypt, it will be best to expose them to the north.

Mr. Miller says, that the best soil for a vineyard, in England, is that whose surface is a rich sandy loam, and not above a foot and an half, or two feet deep, lying upon gravel or chalk; either of which bottoms is equally good for vines. If the soil is deep, or the bottom either a clay or strong loam, it is by no means proper for this purpose: for though the vines may shoot vigorously, and produce a great quantity of grapes; yet we have not sun to ripen them sufficiently. If the soil is too deep, the roots of the vine will run to too great a depth to receive the influences of the sun and air; whence the juices of their fruit will be crude.

According to him, our vineyards should be planted on the north side of a river, upon an elevation inclined to the south, with a very gradual descent, that the superfluous moisture may be the better drained off. Yet if the ground slopes too much, it is by no means proper for this purpose. Hills to the north, as they shelter the vineyard from cold, and reflect the heat, will be of great advantage. The country round about should be open and hilly, to preserve the air dry. The vineyard should be open to the east, that it may enjoy the morning sun, to dry up the superfluous moisture.

Dr. Beal, in N^o. 116 of the Philosophical Transactions, after having mentioned some instances of the warmth arising from stones under ground, especially lime-stone, and some kinds of pebbles, is of opinion, that, as I observed before (quoting this very passage more at large), many of our hills and rocks might be greatly improved: for it would be no hard task, says he, to shovel down the shallow and mossy turf from the steepest declivities, into places, where it may have some receptacle or stay; and there to impregnate it, with the spade and compost, for garden or vineyard.

The ground must first of all be cleared of the roots of trees or shrubs, or whatever else can be a hindrance to the diggers, or might afterward press down the trenched earth, by its weight, or by the treading of those employed in carrying it off. It is of great importance that the earth be kept extremely loose, even, if possible, without a foot touching it, in order that the mould, being all equally stirred, may easily give way to the young tender roots, wherever they extend themselves, and instead of obstructing them by its hardness, receive them into its tender nourishing bosom, which, in that state, readily admits the showers and other influences from above, and dispenses them equally to all parts, for the nourishment of the young plants.

A plain or valley must be trenched two feet and an half deep, and a rising ground three. A steeper hill must be trenched four feet deep: for when the mould is turned down from a higher place, it can hardly be thrown up again to a sufficient depth, unless the trenches are made deeper. Besides, I never approve, says Columella, of planting a vine less than two feet deep, even in a valley; for it is better not to plant it at all, than to leave its roots too near the surface suspended from the nourishing moisture, which lies low, except where springs rise near the surface: there indeed the ground must not be trenched above a foot and a half deep.

The trenches must be made equally deep all the way to the bottom, the sides being perpendicular, and the ground marked out by a line, which must be carried forward as the work proceeds, always at equal distances, till the whole ground is equally trenched. Where the bottom is of a binding nature, it is of great advantage

to lay in the bottom of the trenches, small stones, or other rubbish, to carry off the water, which otherwise, stagnating there, would chill the tender roots. In order to do this the more effectually, the bottom of the trenches are made somewhat convex towards the middle, the better to convey the water to drains cut at the extremities of the vineyard.

If necessity forces to replant an old vineyard, all remains of the old vines must be extirpated. The ground ought then to be dunged with old dung, if it can be had, if not with new, and trenched most carefully, picking out every remaining root, which should be collected and burnt. The trenched earth should then be covered with old dung, which does not breed weeds, or with fresh earth brought from among thickets. Columella advises particularly, to have a careful overseer to inspect the workmen, and to be watchful that they do not make baulks.

Mr. Miller, instead of trenching the ground as the ancients did, proposes giving it a summer fallow, plowing it as deep as the soil will admit of, and clearing it of roots, weeds, or whatever else can obstruct the growth of the plants.

Columella advises great care to be taken in the choice of the vine from which the cuttings are taken, and is therefore against purchasing strange plants at a venture, which may come from a soil and climate different from that they are intended for, and may not be of the sort of vine which is desired. A vine cannot be said to be fruitful, because it bears many grapes; for this may arise from the largeness of the trunk, and the great number of bearing shoots, which may have but a single bunch on each. If several bunches of grapes are seen to hang from each shoot: if from each bud left the former year, shoots with fruit spring forth; if the shoots which spring out of the trunk of the vine have some bunches; and if even the secondary shoots, or those which grow out the present year's shoots, bear grapes; that vine may undoubtedly be esteemed fruitful, and fit to afford cuttings. Whoever has this much at heart, will mark the vines which have been the most fruitful, and have yielded the ripest and soundest grapes, with ochre and vinegar, that it may not be washed off by the rain. Nor is this to be done for one year only; but the vines ought to be examined for three or more vintages, to know whether they preserve the same degree of fruitfulness: for then it will be certain, that the fruitfulness must be owing to the good quality of the vine, and not to a favourable season. Whatever grapes come to their full maturity without being rotted or damaged, for several seasons running, will yield more and higher flavoured wine, than any others.

It is not enough that the stock from which the cuttings are taken be fruitful, but they must also be taken from those parts of it which promise the greatest fruitfulness. Those which grow from the stem or old wood of the vine, seldom bear fruit, or produce fruitful vines. Those which grow from the summit of the vine are reckoned too luxuriant to plant; and though the number of clusters on them may promise fruitfulness, yet they should not be relied on; but rather those which grow out of the middle of the vine, of which the wood is firmer than that of the former. This Columella calls the genital part of the vine; and says, that having followed reason as his guide, and also a long experience, he chooses from that fruitful part of the vine, shoots which, bearing plenty of fruit already, promise fecundity for the time to come. He is not contented with single clusters, but chiefly approves of those which have the most numerous offspring; and adds, that the neglect of these rules has rendered many vineyards less fruitful, indeed some quite barren, when the cuttings have been very improperly chosen.

Some are of opinion, that the whole shoot, as it is taken from the stem, is fit for planting; and for that end, they cut it into pieces of five or six eyes, each of which they plant. Others, with more reason, think that no part of the shoot is fit for being formed into a cutting, but only that part of it which is next to the wood of the former year: for every bearing shoot abounds in fruit below the fifth or sixth eye. The rest

either bears no fruit, or produces only slender twigs. The ancients, says Columella, always preserved some of the old wood to the cuttings: but experience has shewn that this is wrong; for whatever is left of the old wood soon rots, when it is moistened and covered with earth, and kills the tender roots next to it; and when this happens, the whole vine shrivels, or is burnt up. Whatever remains of the old wood should therefore be cut off, where the shoot grows to it, that the shoot may be planted with its own small head. Mr. Miller differs here in opinion from Columella; for he directs, that the shoots should be cut from the old vine, just below the place where they were produced, taking a knot, or piece of the two years old wood to each, which, says he, should be pruned smooth.

Were cuttings, thus chosen, taken from the vines every time they are pruned, for several vintages, and carefully planted, vineyards might be raised, which would yield plenty of the most generous wines; nor need we grudge this delay; for when once we are assured of the fruitfulness of a vine, it may be multiplied by engrafting. This, says Columella, you, Publius Silvinus, can witness: for, from one early vine on your estate, I engrafted the stocks of two jugera of vineyard in two years. How much therefore, may the vine be multiplied from these two jugera, seeing that these are the offspring of only one?

There are two ways of planting vineyards, viz. either with cuttings, or with vines which have already taken root. These last are called quicksets. In the provinces, says Columella, they plant cuttings, for they will not be at the trouble of having nurseries. The expert husbandmen in Italy approve of this practice, because the quicksets are attended with several advantages. They are less apt to die; and by reason of the greater firmness of their wood, they sustain better the extremities of heat and cold, and other intemperatures of the weather: and the transplanting of them quickens their producing grapes. Cuttings may do in a loose yielding mould; but a strong heavy soil must have rooted vines, or quicksets.

Mr. Miller prefers good cuttings to rooted vines, for planting a vineyard; because the roots of vines do not grow strong and woody, as most sorts of trees do, but are long, slender and pliable; and therefore, after they have been taken up, they seldom strike out any fibres from the weak roots: but these generally shrivel and die, and thereby rather retard, than help, the plants in their growth, by preventing the new fibres from pushing out.

This difference of opinion between Columella and Mr. Miller may be accounted for, from the different depths at which they direct the vines to be planted: for were cuttings to be planted two feet and an half deep, no roots would shoot out from their lowest part; and if the rooted vines were planted so superficially in Italy as Mr. Miller advises, they would be dried up by the sun.

Columella directs that the nursery be made, neither in a poor hungry soil, nor in an oily wet one; yet where there is moisture enough; and in a middling rather than a rich soil; because, though cuttings take root soon, and make strong shoots in a rich soil; yet, when transplanted, they shrivel, and seldom recover. It is therefore the husbandman's interest, rather to transplant from a middling soil to a rich one, than from a rich to a poorer. From a rich soil to a rich soil, they will thrive apace. It is not advisable to make the nursery in very poor land, because many of the cuttings will then die, and the others will arrive but slowly at a state to bear being transplanted.

The nursery should be trenched to the depth of two feet and an half, and being formed into beds three feet wide, the cuttings are planted in them at about a foot distance from one another, every way. This may be done either in the spring or in autumn. The spring is best if the climate be cold, or subject to much rain, and the autumn if the climate be warm, and the soil dry, or situated on the side of a hill.

The length of the cuttings should be regulated by the distance between their eyes: for when these are near one another, the cuttings may be shorter, and when they are

are more distant, it should be longer. This length should not exceed a foot, nor should it be less than three-fourths of a foot, left, being planted on the surface of the earth, the cutting should perish with drought in the summer; and, on the other hand, because when a cutting planted too deep has taken root, it cannot be taken up without some difficulty. If the cuttings are planted on the side of a hill, their length may be about fifteen inches on ordinary ground, they need not have above three eyes, which may reduce them to nine inches, but certainly to more than six. In these three eyes are not included the numerous eyes which usually are on the cutting, near the part where it is taken from the stem: besides those numerous eyes, there should be three others, with joints. The cuttings should be planted so deep, as that the uppermost eye may be level with the surface of the ground; because all the sap will then be employed in one single shoot, which will consequently be so much the stronger. They should be planted as soon as possible after they are cut off the vine; and in doing this care should be taken to avoid a strong drying wind, or a scorching sun. It is therefore best to choose a calm day, or at least a day in which there is but little wind. The sun may be kept off by shades, or any covering. The nursery should afterwards be kept clear of weeds, and be frequently dug. Only one shoot should be reared, and that should be fastened to a stick or slender pole, to bear it off the earth. The rest should be carefully rubbed off; and this shoot should be pruned down to two eyes in the autumn. The strongest shoot from these eyes should be reared the next summer; and with this management the cuttings will be fit to transplant at the end of thirty or thirty-six months.

Vines are likewise propagated by layers. For this purpose, a trench is dug four feet every way, that the layer may not be hurt by other roots. A shoot of the last year is then laid down in it, in such manner as to make its end rise at the farther part of the trench. Four eyes are left on that part of the layer which goes to the bottom of the trench, and they are to put out roots. All the eyes between them and the stem should be rubbed off, to prevent the growth of useless shoots. Two, or at most three, eyes are left on the farther end, which rises out of the earth, and all the rest, between them and those at the bottom of the trench, are rubbed off. The layer thus prepared soon takes deep root, and in the third year, it may be cut off from the mother vine. When the shoot is not long enough to rise again out of the earth, Columella thought of the following method. The end of the shoot is brought to the bottom of the trench, and the four lower eyes, left for the roots to shoot from, are covered with earth, as before: but instead of the eyes at the extremity, as in the former way, the two eyes next the surface of the earth, of that part which come from the stem, are left to make shoots, which they readily do, and in the third year, the layer may be cut from the mother vine, as in the other case. In order to encourage the roots to strike out, they need not be covered with the whole depth of earth the first year, unless it should become necessary before the winter, to keep the roots from being chilled by water which might gather in the trench.

The ground being thoroughly prepared, by trenching, harrowing, and clearing it of every thing that can be hurtful to the vine, it is marked out, in order to be planted. The Romans planted their vines five feet asunder in a poor soil, six feet asunder in a middling soil, and at the distance of seven feet from each other in a rich soil. Sometimes too they left a space of ten feet between them, that there might be sufficient room for the strong shoots to extend themselves.

They generally planted their vineyards in a quincunx form, for which they marked out the ground by stretching across it a line trimmed with bits of red cloth, or of some other conspicuous colour, at such distances from each other as it was intended to leave between the rows. A piece of reed was stuck into the earth at each spot indicated by the cloth, and this was repeated till the whole field was marked out in equal distances. The planter followed, and dug a hole at each alternate reed, two feet

and an half deep in level ground, two feet and three quarters if it lay sloping, and three feet deep where the declivity was considerable. He then removed the quicksets from the nursery, taking them up with great care, and transplanted them the very same minute, if that was possible. All their shoots were previously pruned off, except one, which was the soundest and firmest, and of that only two eyes were left above ground. If any of the roots were hurt in taking them up, thro' all possible care was used not to injure them, they were cut off, very smooth. If two plants were set in the same hole, a few stones, of about five pounds weight, were laid between them in the bottom of the hole, to prevent their roots from interweaving together. They were likewise of opinion, that these stones saved the roots from being chilled in the winter, or scorched by the heat of the dog days in the summer. Mago advised to lay the husks and stones of grapes mixed with dung, in the holes, under the roots of the vines, as a means of strengthening them, and of hastening the production of young roots. During the chilling wet of the winter, they gave a warmth; and in the summer, they afforded a nourishing moisture.

Columella disapproved greatly of putting two vines in the same hole, because their roots constantly mingled together, and formed a kind of net-work, which retained too much moisture in the winter, and, by robbing each other of nourishment, proved prejudicial to both. If the soil of the vineyard was poor, Mago directed that the holes should be filled up with rich earth brought from elsewhere. The ground should be a little moist when the vines are planted; but it had better be dry, than mirey wet.

Mr. Miller orders that the ground, which he before directed to be fallowed, be again well plowed in March; and that after having laid its surface even, the rows should be marked out, from south-east to north-west, at the distance of ten feet from each other. He then crosses these rows at the distance of five or six feet, and thereby marks the spot where each plant is to be set. The rows will consequently be, in this case, ten feet asunder, and the distance between the vines in each row will be five or six feet; nearer than which they ought never to be planted. If they are set in squares so near together as six feet, there cannot be room for a sufficient current of air to pass between them when their branches are extended on one side; and for want of that the damps in autumn will be detained among the vines, to the great prejudice of their fruit. In places abroad, continues he, where they regard the quality of their wine more than the quantity, they never plant their vines at less than ten feet, row from row, and some allow twelve: and he confirms the justness of this rule by what happens to other fruits, which are never so well coloured, so early ripe, or so well flavoured, when in close plantations, as when they are produced on trees where the air can circulate freely about them, and the rays of the sun have free access to the branches, whereby the juices are better prepared.

Preferring cuttings to layers, as well as to rooted vines, he directs, that the cuttings be taken from the vine in the autumn, and that their ends, being made smooth, they be laid in the ground, about two inches deep, the rest of the cutting being left at full length; only observing to cover them with dry litter, or peas haulm, in dry frosty weather. In moist weather the covering should be taken off, lest it heat, and make the cuttings grow, which would greatly injure them. In April, which he reckons the best season for planting vines in England, the cuttings should be taken out of the ground, and their upper parts cut off, so as to reduce them to about fourteen inches in length, according to the distance of the buds or eyes. He thinks it of great service to leave their tops on all the winter, because the air would otherwise penetrate the wounded part, and greatly injure the remaining eyes. The lower ends of the cuttings should be put in water, about three inches deep, setting them upright, for six or eight hours, before they are planted, in order to moisten them and open their pores: then, at the center of every cross mark, before made, a hole should

should be dug with a spade, about a foot deep, and one strong cutting should be set, a little sloping, in each of these holes, which should afterwards be filled up immediately with earth pressed down gently to the cutting. This earth should be raised about three inches round each cutting, so as just to cover its upper eye or bud, to prevent the wind and sun from drying it; for only that upper bud will shoot when the plant is thus managed.

Mr. Miller justly blames his countrymen for planting their vineyards, in the few attempts that have been made of them in England, with such grapes as are the sweetest and best for eating; this being contrary to the general practice abroad, where the rough austere grapes, which are by no means palatable, but which are by experience found to afford a noble rich wine, are preferred. This is also agreeable to the constant practice of the makers of cyder, who observe, that the best eating apples yield but a poor juice, and that the rough sorts afford a strong vinous liquor. I believe, continues he, that it will be found true in all fruits, that where the natural heat of the sun ripens and prepares their juices, so as to render them palatable; whatever degree of heat these juices have more, either by fermentation, or from any other cause, will render them weaker, and less spirituous. Of this we have many instances in fruits: for if we transplant any of our summer or autumn fruits, which ripen perfectly in England without the assistance of art, into a climate a few degrees warmer, these fruits will be mealy and insipid. So likewise, if we bake or stew any of these fruits, they will be good for little, because they will lose all their spirit and flavour by the additional heat of the fire: and on the other hand, many fruits which are not even eatable whilst raw, are thereby much improved. Some of these, which have been transplanted into a warmer climate, have been so altered by the greater heat of the sun, as to excel the very finest of the fruits that are ripened in this country. The grape most likely to succeed in England, is the Auvernat, or true Burgundy grape, which thrives very well in several places north of Paris.

Columella advises every prudent husbandman to stock his vineyards with different sorts of vines, because the weather is not so equal in any year, but that it may be more hurtful to some, than to others. If, therefore, he plants but one kind of vine, and the weather happens to be prejudicial to it, he will be deprived of his whole vintage: but if he has vineyards of various sorts, some of them may escape, and yield him fruit. He recommends particularly, that each kind of vine be planted by itself; because otherwise one of the following inconveniencies will ensue; viz. either he must gather his late grapes with those that are early ripe, which will cause an acidity in the wine; or if he waits till the late fruit come to maturity, the early grapes will be rotten, or destroyed by birds or rain: for the distinguishing of each kind cannot be trusted to the gatherer's discretion. The flavour of the ripe grapes is hurt by the addition of the unripe; nor will the wine made of them both, mixed together, keep till it is old. When each sort is separate, the vine dresser will be able to prune and manage it in the most proper manner.

He cautions his readers strongly against the too prevailing opinion of those who imagine, that the chief care and trouble are at an end when the vineyard is planted. He observes, that the vine is a tender delicate shrub, which can very ill bear neglect, and which, when young, often destroys itself, by being permitted to run too much to wood, or to bear too great quantities of fruit. Most people are so intent on having much fruit that they load the vine with too many bearing branches, without having any regard to future years, or to posterity; and then complain, that their vineyards do not answer their expectation, when they themselves have destroyed them, either through covetousness, negligence, or ignorance. When the vine has arrived at its full strength and maturity, it can better bear some neglect. Believe, Silvinus, says this excellent husbandman to his friend, what I know from my own experience, that a vineyard judiciously planted with good vines, and well cultivated, never fails to bring its owner a most abun-

dant return. This he confirms from Græcinus, by the example of Pavidius Veterensis, who had two daughters, and a farm planted with vines. He gave the eldest daughter one third of his farm, on her marriage, and yet had as much fruit from the remaining two thirds, as he had before from the whole. He afterwards gave half of the remainder to the younger daughter, on her marriage, and still had as good an income as at first. This, says Columella, must arise from the remaining thirds being proportionally better cultivated, than the whole had been before.

Mr. Miller says, that as the space between the rows of vines is great, the ground there may be sown or planted with any kind of esculent plants, provided they are kept at such distance from the vines, that these be not injured by them. This husbandry, which is also the method in France, may be continued three or four years, till the vines come to bearing: but after that, no sort of crop should be set between them in the summer; because, the clearer the ground is kept, the more heat will be reflected to the grapes. After they are gathered, a crop of coleworts, for spring use, may indeed be planted between the rows, and the stirring of the ground for them will be of great service to the vines.

From the time that the vine first begins to bud, all superfluous shoots must be carefully rubbed off; that the nourishment may be consumed by those only which are to be reared. Two shoots are generally set apart for growth; the one as a reserve, in case the other should fail. As soon as they rise, a prop should be set in the ground, for each of them. This prop should be slender, because the weak tendrils of the vine will then lay hold of it more easily than if it was thick. As the shoots grow up, they are tied to the props with a soft slack binding, till their tendrils have encircled them; and at less than four feet from the ground, sticks are fastened across the props, that the vines may extend laterally, and thereby be the less exposed to the force of winds. In nurseries, this cross stick, or rail, should not be above a foot high, lest strong winds should tear the young plants out of the earth. When the shoots are grown nearly to their full height, their tops are broken off, to make them increase in thickness and strength, rather than run up into a needless length. The most thriving shoot, which is to be the leading wood branch, must be trained up strait, and kept clear of secondary shoots for three feet and a half from the ground: but such as grow above that height may be permitted to remain till the autumnal pruning; for if they are all rubbed off, new shoots will immediately spring out from other eyes, so that, perhaps, none may be left for the next year's buds. The shoots which are rubbed off from time to time should never be suffered to grow so strong, as not to be easily displaced with the finger; for the heat in summer hurts the vine greatly wherever it has been wounded with a knife. For this reason, if it should be absolutely necessary to use the knife, a piece of the shoot which is cut off should be left prominent from the stem, to stop the effect of the heat, which, in that case, will not proceed farther.

During the second year's growth, the ground should be kept constantly stirred, as in the preceding year, only with this difference, that it may be done once seldom. The weeds must be kept under, till the vines, by extending their branches, shade the ground, and thereby prevent their growing under them. All superfluous twigs must be constantly rubbed off as before, and only one shoot should be permitted to grow up. The props must be continued as in the former year. If any of the plants died in the first year, two shoots may be reared up on the strongest of the vines next the vacant space; one to form the standard shoot, and the other to be made a layer, to supply the place of the dead vine. After the vintage, this shoot must be laid down, or if it be not long enough to rise out of the earth on the other side of the hole, only its extremity need be put into the ground, as already directed. Next year, the layer must be cut half through, in the bend, that so it may not rob its mother too much, but be brought to be nourished by its own roots. When it is two years old, it may be cut

off from the mother plant, and its root must be carefully ablaqueated, that it may strike the deeper into the earth. If the neighbouring vines cannot furnish layers, a rooted vine must be brought from the nursery; for it is too late to recruit a vineyard, when we should be gathering its fruit.

For the third year's growth, the vine must be supported with stronger and higher props than before. These should be fixed, either a foot from the vine, that they may not hurt the roots, and that so the vine dresser may dig all round the vine; or in the middle between two vines. The first way is the best, because the vine and prop mutually support each other. If the prop is fixed near the vine, it should stand so as to shelter the vine from the north. It is of great importance that the prop stand very firm. On each upright prop must be put a cross pole, sufficiently strong to bear the weight of the fruit. This year the vine may be permitted to make two shoots, to cover the cross pole on each side with bearing branches, unless the vine be yet too weak to nourish them. All superfluous shoots and twigs must be carefully rubbed off. The ground must be frequently stirred, to keep it loose, and destroy weeds. The roots must be laid bare in October. The places of dead plants must be supplied, as directed for the preceding year, and this must be a constant rule every year. When a vine dies after it has stood for some years, the hole or trench which is made for the layer or young plant, must be dug deeper and wider than it need to be after a young vine, in order that all the roots of the old one may be taken away. The trench should then be partly filled with fresh earth, or a good deal of dung mixed with the former soil. If each side of the vine has produced two shoots, and both of them shew plenty of fruit; yet one must be taken away, that the other may thrive the better, and bring its fruit to greater perfection.

When this vintage is finished, the vine may be pruned so as, in a fertile soil, where it thrives well, to leave three eyes, to produce bearing shoots for the next year; but four eyes should seldom be left. The binder must separate these shoots, and tie them to the frame, to which another cross pole is now added, in the form of a star: or these cross poles may be supported by four props. The shoots spread in this manner become a counterpoise to each other. These cross frames are the more necessary if the vines are exposed to stormy winds, or if they stand on steep declivities, where every means of propping them is wanted. In warm and dry situations, the frame may be extended on all sides, in the form of an arched roof, the better to shade the thirsty earth: but in cold and frosty climates, the vines must be supported only on single frames or espaliers; for then the earth is more easily warmed by the sun, the fruit is more thoroughly ripened, and a freer passage is afforded to the air. The frames should not be lower than four feet, nor higher than seven. Young vines should be brought to this height gradually. The moister the soil and climate are, the higher should be the frame; for there, the thriving state of the vines admits of raising their branches, and their fruit being thereby raised higher from the earth, is the less liable to rot. In this situation, the winds blow freely through them, and dry up the dews and noxious fogs; the vines blossom more kindly, and yield a better wine. On the other hand, vines in a poor soil, on a steep declivity, and subject to scorching heat, require lower frames. If the vineyard is well placed, the best height is five feet; though there is no doubt but that the wine is the better flavoured, the higher the frames are.

If the vineyard is intersected by foot paths which divide it into a number of small partitions, the sun and wind have the freer access to the vines; as hath also the eye of the master, which is of great advantage. The labour too seems less to the vine-dressers, when it is thus portioned out in small divisions. The paths afford convenient passage for the grape gatherers, for those who repair the frames, and for bringing in manures, or what else may be wanted. The owner can likewise distinguish the fruitfulness of each spot, and thereby be enabled to apply proper remedies. Where the rows of vines stand

very far asunder, too much ground is generally left uncultivated between them; one half of which is commonly used for alleys, or foot paths.

The trunk of the vine should be carried up strait to within a foot of the top of the frame; not only to conduce to its beauty, but also to its fruitfulness and duration: for the moisture which nourishes plants never has so free a motion through a crooked stem, as it has through a strait one; the bendings proving so many lets or hinderances to the equal circulation of the sap. The top of the vine should be fastened to the prop, so as to prevent its being bent, or dragged down, when it is loaded with fruit; and for greater security in this respect, the arms, or branches, which proceed from thence, should be trained along the frame, and tied to it, so that only those parts of the shoots on which the fruit grows may hang sloping down from the edge of the frame: nor should this be at right angles from the binding, because that position would endanger their breaking. When thus situated, they are less exposed to rain and hail, than when they are fastened to the frame. They should however be tied up before the grapes are ripe, to guard against their being rotted by the dew. When the vine is five years old, it will be sufficient to leave one fruit bearing shoot on each of its arms, or branches: but, some years after, when it has attained its full strength, a luxuriant vine, in a rich soil, may convey nourishment to eight fruit-bearing shoots; and, indeed, unless it be checked by a quantity of fruit, it will waste itself in wood and leaves: whereas a weak vine, in a poor soil, will soon be exhausted if it is burthened with fruit.

The branches of a vine should never be suffered to grow bigger than the stock: but, to supply their place, shoots issuing from their sides should be trained, and as soon as these begin to bear fruit, the old hard wood should be cut away. Fewer bearing shoots should be left on the branch which extends northward, than on that which is directed toward the south; because this last requires the greatest shelter from the scorching heat of the sun, and therefore stands most in need of leaves. All suckers must be cut away from the root, and the place whence they sprung smoothed with a knife; for then it will soon skin over. No shoots must be suffered to grow from the trunk, nor should any knobs or warts be left on it. All dry, cracked, and shrivelled bark, must be taken off. Moss likewise, which shackles the vine, as with a fetter, and soaks it with its pernicious moisture, must be carefully scraped off: and if the trunk is any way damaged, or rendered hollow by rain or insects, it must be cut away to the sound wood. The wound should then be covered with earth which has been moistened with lees of oil; for this will defend it from insects, sun, and rain, and therefore make it heal the sooner. All broad, ill-shaped, withered sprays, and such as hang downward, commonly called dangles, must be cut off; and the strait shoots must be preserved. When the vine is freed from all these incumbrances, it will thrive the better, and yield the purer wine. The vine dresser should be particularly attentive, that all wounds in the solid wood be made sloping and round; because they afford the least lodgment to water, and are the soonest closed.

Sometimes a strong shoot strikes out of the fork of two of the leading branches, and cripples one of them. In this case, the crippled branch must be cut off, and the young shoot reared in its stead: but if it be taken in time, the young shoot should be cut off. Whatever grows out of the trunk of the vine must be cut away so smooth, that no water may lodge in the scar: but what grows on the young shoots of the same year, should be cut off between the two first eyes; lest by cutting it too near the main shoot, this also should be hurt by the wound, and the neighbouring bud be killed.

As to the length of the fruit-bearing shoots, there is no general rule; for it may depend greatly on the quality of the soil, and the vigour of the vines, as well as on the distance between the eyes; for where the joints are shorter, a less length of shoot may be equally loaded with fruit. The last year's vintage should also be considered: for those parts of the vine which then bore great plenty

plenty of fruit, must be spared in the following year; and such as produced but a small quantity, may be loaded the more. Most particular care should be taken, that every cutting instrument which touches a vine, be sharp and well tempered; for otherwise, the labour of the vine-dresser is greater, and the vine is rather torn than cut; so that there then remains an uneven scar, in which the juices putrify, so as often to kill the vine.

In the autumn, the vines which have produced two strong shoots of equal vigour, must be cut down to three eyes each. When they have a strong shoot and a weak one, the strong shoot must be shortened to three eyes, and the weak one to two: and such as have but one strong shoot, should be shortened to two eyes.

In March of the third year, two stakes should be placed down by the side of all such vines as have two shoots, at such distance on each side of the plant, that the shoots, fastened thereto, may form an angle of forty-five degrees, with the stem: but they should not by any means be bent down horizontally, as some injudiciously advise and practise: for the branches, then lying too near the earth, are generally injured by the damps which arise from thence, especially if they have fruit, which is never so well tasted, nor so ripe, as when they are a little elevated. In May, the strong shoots should be fastened to the stakes.

If the two shoots of the former year have produced two strong branches, the uppermost of these shoots upon each branch should be shortened down to three good eyes, not including the lower eye, which seldom produces any thing more than a weak dangling shoot; and the lower shoot should be shortened to two good eyes; these being designed to yield vigorous shoots for the next year, as the former are to bear fruit. Where the vines are weak, and have not produced more than two or three shoots in the summer, but one of these should be left with three eyes, for bearing; the other must be shortened down to two, or if it be weak, to one good eye, in order to obtain strong shoots the following summer: for nothing is more injurious to young vines, than leaving too much wood upon them, or over-bearing them.

In March of the fourth year, all small horizontal roots, which may have been produced near the surface of the ground, should be cut off close to the trunk. A stake should be placed about sixteen inches from the root, on each side of the vine, and the bearing branches should be fastened thereto. Then another, and taller, stake should be thrust down near the foot of the vine, and to this should be tied the two shoots which were pruned down to two eyes. In May the shoots which shew fruit must be fastened to the stakes, with bafs, to prevent their being broken, until they are extended to three joints beyond the fruit; when they should be stopped, by nipping off the end: but the shoots, which are designed for bearing the next year, should be trained upright to the middle stake; by which method, neither of them shading the other, each will enjoy the benefit of the sun and air. The shoots should be constantly kept in their right position, to prevent the inverting of their leaves; for when that happens, it greatly retards the growth of the fruit.

Mr. Miller very justly censures the absurd practice of those who pull off from their vines the leaves which grow near the fruit, in order to let in the rays of the sun, to ripen it; not considering how much they thereby expose their fruit to the cold dews which fall plentifully in autumn, and which, being imbibed by the fruit, greatly retard it: besides, no fruit will ripen so well when it is entirely exposed to the sun, as when it is moderately screened with leaves. By pulling off the leaves, which are absolutely necessary to prepare the juices before they enter the fruit, and of which juices the gross parts are perspired by them; the fruit must either be deprived of nourishment, or else, some of the gross particles will enter with the more refined parts of the juices, and thereby render the fruit worse than it would be if the leaves were left upon the branches.

Mr. Miller directs, that the vineyard, being now arrived at a bearing state, should be treated after the following manner. Too many branches should never be

left upon a root, not should those be too long: for although a management contrary to this may be productive of greater quantity of fruit, yet that fruit will not be so well nourished, nor will its juice be so good, as when it is but moderately plentiful: neither will the roots of the plants be so much weakened in this last case, as they must be in the former. The ground should be constantly kept clear of weeds; and no sort of plant should be suffered to grow on it, excepting that which it is intended to cultivate. It should be manured every third year, according to the nature of the soil. If the land is stiff, and inclinable to bind on the surface, sea-sand, or sea-coal ashes, are very good manure: but if it is loose and dry, a little lime mixed with dung will do it the most service. After each spring digging, the stakes are fixed as already mentioned, and the same care and management of the vines, as was before directed, must be continued. Mr. Arnoux says, that, in Burgundy, they bind the branches of the vine in an horizontal position, at the height of half a foot from the earth, to props three or four feet high, stuck into the ground, without any order, at the distance of about a foot asunder. They tie the shoots to these props as they extend in length, and find in this method the advantage that one branch is not shaded by another, but for as little a time as is possible.

Columella directs, that the props and frames be carefully examined after every pruning, and that whatever is amiss in them be repaired. Broad and flat props are preferable to round ones, and oak is the best wood they can be made of. Next to them, are round props of juniper, laurel, forest pine, and elder. Such as are rotten must be taken away, and new ones put in their stead. The bindings should be new every year. The ligature which fastens the stem to the prop should not be always in the same place, lest it should occasion a wound. The four branches should be tied gently to the cross poles, so as not to twist or bend them much. The shoots should be fastened so as that, when they grow beyond the frame, they may go shelving from it, and not hang by their binding, which would be apt to break them, especially when loaded with fruit. When two branches are so near together as to go to the same side of the frame, another pole should be placed between the cross ones, for one of those branches to be fastened to.

Those who are curious in gardening know what great things Dr. Agricola boasts of from the use of his mummies, in rearing the tenderest plants, as well as in raising forest trees from cuttings. The lees of oil, as Columella directs, mixed with fine earth, to give it a consistence, may probably answer the same purposes. Where lees of oil cannot be had, some other bitter vegetable substance might be contrived, which, being free from the acrid oil in all turpentine (as in Agricola's mummies) might prove very friendly to plants, and be particularly useful in preventing their wounds from bleeding, and in preserving them from being scorched by the sun, or hurt by insects. It is necessary that this substance be bitter, that it may hinder the insects from preying on the tender juicy fibres, for instance, of the vine, wherever a wound is made. Even loam, by itself, is found to be serviceable for these purposes; and so is either goat's, sheep, or cow's dung, well mixed with a due proportion of earth. The vine-dresser should therefore constantly have some such substance ready to apply to every wound he makes in the vine. Perhaps too, it may prove useful to the cuttings, when these are planted, by retaining the juices, till they are employed in their office of vegetation, and thereby help to save them from being parched up by drought, as well as to render them less liable to be soaked in a wet soil, or by a rainy season.

VINEGAR, *Acetum*, an acid penetrating liquor, prepared from wine, cyder, beer, &c. of considerable use both as a medicine and sauce.

The process of turning vegetable matters to vinegar, is thus delivered by Dr. Shaw: take the skins of raisins, after they have been used in making wine; and pour three or four times their own quantity of boiling water upon them, so as to make a thin aqueous mixture. Then

set the containing cask, loosely covered, in a warmer place than is used for vinous fermentation; and the liquor in a few weeks time will become a clear and sound vinegar; which being drawn off from its sediment, and preserved in another cask, well stopped down, will continue perfect, and fit for use.

This experiment shews us a cheap and ready way of making vinegar from refuse materials; such as the husks of grapes, decayed raisins, the lees of wine, grounds of ale, beer, &c. which are frequently thrown away as useless. Thus, in many wine countries, the marc, rape, or dry pressing of grapes are thrown in heaps, and suffered to putrify unregarded; though capable of affording as good vinegar, as the wine itself. In some places they bury copper-plates in these husks, in order to make verdigrise; but this practice seems chiefly confined to the southern parts of France. Our present experiment shews us how to convert them to another use; and the direction extends to all the matters that have once undergone, or are fit to undergo, a vinous fermentation, for that all such matters will afford vinegar. Thus all our summer-fruits in England, even black-berries; all the refuse washings of a sugar-house, cyder-pressings, or the like, will make vinegar, by means of water, the open air, and warmth.

The whole process, whereby this change is effected, deserves to be attentively considered. And, first, the liquor to be thus changed, being kept warmer than in vinous fermentation, it, in a few days, begins to grow thick, or turbid; and without throwing up bubbles, or making any considerable tumult, as happens in vinous fermentation, deposits a copious sediment. The effect of this separation begins to appear first on the surface of the liquor, which gathers a white skin, that daily increases in thickness, till at length it becomes like leather; and now, if continued longer in this state, the skin turns blue, or green, and would at last grow solid, and putrify: therefore, in keeping down this skin as it grows, and thrusting it gently down to the bottom of the vessel, consists much of the art of vinegar making, especially from malt. For the difference between vinous and acetous fermentation, see FERMENTATION.

Method of making Cyder VINEGAR. The cyder, the meanest of which will serve the purpose, is first to be drawn off fine into another vessel, and a quantity of the must, or pouz of apples, to be added; the whole is set in the sun, if there be a conveniency for the purpose; and, at a week or nine days end, it may be drawn off. See CYDER.

Method of making Beer VINEGAR. Take a middling sort of beer, indifferently well hopped; into which, when it has worked well, and is grown fine, put some rape, or husks of grapes, usually brought home for that purpose: mash them together in a tub; then, letting the rape settle, draw off the liquid part, put it into a cask, and set it in the sun as hot as may be; the bung being only covered with a tile, or slate stone: and in about thirty or forty days it will become a good vinegar, and may pass in use as well as that made of wine, if it be refined, and kept from turning musty.

Or thus: to every gallon of spring water, add three pounds of Malaga raisins: which put into an earthen jar, and place them where they may have the hottest sun from May till Michaelmas: then, pressing all well, run the liquor up in a very strong iron hooped vessel, to prevent its bursting: it will appear very thick and muddy, when newly pressed; but will refine in the vessel, and be as clear as wine. Thus let it remain untouched for three months, before it be drawn off, and it will prove excellent vinegar.

Method of making Wine-VINEGAR.—Any sort of vinous liquor, being mixed with its own fœces, flowers, or ferment, and its tartar, first reduced to powder; or else with the acid and austere stalks of the vegetable from whence the wine was obtained, which hold a large proportion of tartar: and the whole being kept frequently stirring in a vessel which has formerly held vinegar, or set in a warm place full of the steams of the same, will begin to ferment a-new, conceive heat, grow sour by degrees, and soon after turn into vinegar.

The remote subjects of acetous fermentation are the same with those of vinous; but the immediate subjects of it are all kinds of vegetable juices, after they have once undergone that fermentation which reduces them to wine: for it is absolutely impossible to make vinegar of must, the crude juice of grapes, or other ripe fruits, without the previous assistance of vinous fermentation.

The proper ferments for this operation, whereby vinegar is prepared, are, 1. The fœces of all acid wines. 2. The lees of vinegar. 3. Pulverized tartar; especially that of Rhenish wine, or the cream or crystals thereof. 4. Vinegar itself. 5. A wooden vessel, well drenched with vinegar, or one that has been long employed to contain it. 6. Wine that has often been mixed with its own fœces. 7. The twigs of vines, and the stalks of grapes, currants, cherries, or other vegetables of an acid austere taste. 8. Bakers-leaven, after it is turned acid. 9. All manner of ferments, compounded of those already mentioned.

The French use a method of making vinegar different from that above described. They take two very large oaken vessels, the larger the better, open at the top; in each of which they place a wooden grate, within a foot of the bottom: upon these grates, they first lay twigs, or cuttings of vines, and afterwards the stalks of the branches, without the grapes themselves, or their stones; till the whole pile reaches within a foot of the brim of the vessels: then they fill one of these vessels with wine to the very top, and half fill the other; and with liquor drawn out of the full vessel, fill up that which was only half full before; daily repeating the same operation, and pouring the liquor back from one vessel to the other; so that each of them is full, and half full, by turns. When this process has been continued for two or three days, a degree of heat will arise in the vessel, which is then but half full, and increase for several days successively, without any appearance of the like in the vessel which happens to be full, during those days; the liquor of which will still remain cool: and as soon as the heat ceases in the vessel that is half full, the vinegar is prepared: which, in the summer, happens on the fourteenth or fifteenth day from the beginning; but in the winter, the fermentation proceeds much slower: so that they are obliged to forward it by artificial warmth, or the use of stoves.

When the weather is exceeding hot, the liquor ought to be poured off from the full vessel into the other twice a day: otherwise, the liquor would be overheated, and the fermentation prove too strong; whence the spirituous parts would fly away, and leave a vapid wine, instead of vinegar, behind.

The full vessel is always to be left open at the top, but the mouth of the other must be closed with a cover of wood, in order the better to keep down and fix the spirit in the body of the liquor; for otherwise, it might easily fly off in the heat of fermentation. The vessel that is only half full seems to grow hot, rather than the other, because it contains a much greater quantity of the vine twigs and stalks, than that, in proportion to the liquor; above which the pile, rising to a considerable height, conceives heat the more, and so conveys it to the wine below.

Vinegar is not a pure or simple acid, like those of the mineral kingdom: the vapidity and putrefaction to which it is subject, and its chemical analysis, discover, that it participates largely of an oily matter. Distilled by a moderate heat, not exceeding that of boiling water, it yields first a phlegmatic liquor, afterwards a slightly acid one, which is succeeded by stronger and stronger acids, till the matter in the distilling vessel becomes thick and unctuous like honey: the vinegar prepared from malt liquors contains more of this viscous substance than that of wine, and hence is more disposed to become ropy and slimy in keeping. This residuum, urged with a stronger fire, gives over an empyreumatic oil, and a penetrating acid spirit tainted with the ill smell and yellow colour of the oil. There now remains a black coal, which, burnt into white ashes, yields a considerable proportion of fixed alkaline salt.

Pure fixed alkaline salt, saturated with the colourless distilled liquors, and afterwards exsiccated, contracts a yellowish

yellowish or brown tinge; and thus betrays, that the acid still retains a portion of the oil. On gently melting the dry salt, the oily matter burns to a black coal, which separates on dissolution in water: the solution exhaled to dryness, leaves a perfectly white neutral salt, containing the pure acetous acid combined with the alkali. On adding to this compound a little oil of vitriol, the acetous acid is disengaged, and may now be collected by distillation, in a highly concentrated state, and of a very pungent volatile smell.

The quantity of fixed alkaline salt, which vinegar is capable of saturating, is one of the surest criterions of its strength. The best of the German vinegars, according to Stahl, saturate little more than one fortieth of their own weight; the French vinegars, examined by Geoffroy, above one thirty-fifth, and some of them no less than one twelfth; the common distilled vinegar of our shops, about one twentieth. By congelation, and distillation from alkalies and other bodies, the acid may be so far concentrated as to saturate near equal its own weight; a greater degree of strength, than even the mineral acid spirit of sea-salt can easily be brought to.

The acetous acid, however purified or concentrated, differs essentially from all the others: from the native vegetable acids, in subtility and volatility; nor being obtainable in the form of a concrete salt, which most, perhaps all, of the native ones are; and rising in distillation with a moderate heat, which none of the native ones have been found to do; the acid juices giving over, in the heat of boiling water, only their aqueous fluid, and having greatest part of their acidity destroyed by a stronger heat: from the mineral acids, in its habitude to different bodies, and the nature of the compounds which it forms with them: thus, whatever alkaline, earthy, or metallic substance, the acetous acid be combined with, the addition of any mineral acid will disjoin them, the mineral taking the place of the acetous: neutral salts, composed of the acetous acid and fixed alkalies, dissolve, totally and plentifully, in rectified spirit of wine, whilst those, composed of the same alkalies and mineral acids, are not at all soluble in that menstruum: in this property, the acetous acid differs also from most, perhaps from all, of the acids of its own kingdom:—and from all acids in general, in its peculiar odour.

Vinegar dissolves the elixated ashes of vegetables; animal earths, purified by incineration, or when naturally blended with but little gelatinous matter, as in shells; the earth of alum; and the mineral calcareous earths. The solubility of calcareous earth in the acetous acid, and its precipitability by that of vitriol, afford a ready method of discovering the sophistication of vinegar, said to be sometimes practised, with vitriolic acid; and likewise of purifying it when so sophisticated. If a saturated solution of any calcareous earth, as chalk, made in strong vinegar, be added to such as is suspected of containing vitriolic acid, no change will ensue if the vinegar was pure; but if it contained even a minute portion of that acid, the mixture will immediately become milky, and on standing for a little time deposit a white sediment: if the calcareous solution be gradually dropt in, so long as it produces any milkiness or cloudiness, all the vitriolic acid will be absorbed by, and precipitate with the chalk.

It dissolves, among metallic bodies, zinc, iron, copper, tin, lead, bismuth, and regulus of antimony; the two last in very small quantity, but sufficient to give a strong impregnation to the vinegar. It dissolves lead more easily when reduced into a calx, than in its metallic state: boiled even with the glass of lead, or in the common glazed earthen vessels, in the glazing of which, this metal is a principal ingredient, it extracts so much as to become strongly tainted with the pernicious qualities of the lead.

It dissolves the vegetable inspissated juices, and several of the gummy resins, and extracts the virtues of sun dry plants in tolerable perfection; but at the same time its acidity makes a notable alteration in them, or superadds a virtue of a different kind. Some drugs however, for particular purposes, it excellently assists or coincides with, as garlic, squills, ammoniacum: and in many

cases, where this acid itself is principally depended on, it may be advantageously impregnated with the flavour of certain vegetables: most of the odoriferous flowers impart to it their fragrance; and the blue, bright red, and some others, tinge it at the same time of a fine purplish or red colour.

It mingles equally with blood and its serum, and with most of the fluids of animals; not thickening or coagulating them, like the acids of the mineral kingdom; but tending rather, as Boerhaave justly observes, to attenuate and resolve coagulations. It is likewise, when taken internally, less stimulating than the mineral acids, and less disposed to affect the kidneys.

This mild unctuous acid is a medicine of great use in the different kinds of inflammatory and putrid distempers, both internal and external. It is one of the most certain antiphlogistics and sudorifics in high fevers, and one of the best preservatives against pestilential and other putrid contagious contagions. Fainting, vomiting, lethargic and hysteric paroxysms, are likewise frequently relieved, by vinegar, applied to the mouth and nose, or received into the stomach: lethargic persons are often found to be excited more effectually by vinegar blown into the nose, than by the far more pungent volatile spirits. Boerhaave observes, that this acid counteracts, in a peculiar manner, the effects of spirituous liquors.

The daily use of vinegar, with food, is salutary in hot bilious dispositions, and wherever there is a tendency to inflammation or putrefaction. It is prejudicial to children, to aged, hysteric, and hypochondriacal persons, in cold pale phlegmatic habits, where the vessels are lax, the circulation languid, and the power of digestion weak. It tends in all cases, if used freely, to prevent corpulence; Hoffmann suspects that it produces this effect by impeding the formation of chyle, or destroying the union of the unctuous and serous fluids of which chyle is composed; an effect common to all acids, as appears from their coagulating milk and artificial emulsions. Great corpulence have been reduced by the liberal use of vinegar, the acid commonly employed for this purpose, but not with impunity; diseases succeeding, which eluded the power of medicines, and proved at length fatal.

Combinations of vinegar with different earthy bodies differ in virtue according to the nature of the earth. A solution of the aluminous earth in this acid is strongly styptic; of vegetable earths, or magnesia alba, bitterish and gently purgative: both these solutions are milder, and less ungrateful, than those of the same earths made in the mineral acids, and though as yet unknown in practice, certainly deserve to be introduced. Solutions of different animal and the calcareous mineral earths are bitterish and subaustere, in various degrees; and supposed to act as mild resolvents, subastringents, or diaphoretics.

Combinations of vinegar with fixt alkaline salts, are useful aperients, diuretics, and cathartics. Two drams of the alkali, dissolved in as much vinegar as is sufficient to saturate it, will occasion ten or twelve copious watery stools, and a plentiful discharge of urine, without griping or fatiguing the patient. Mixtures of alkali and distilled vinegar, evaporated to a dry salt, are kept in the shops; either in a brownish oily state, as obtained by simple evaporation; or purified to perfect whiteness, by gentle fusion and solution in water: these preparations are given in doses of ten or twenty grains as mild aperients, and to a dram or two as purgatives and diuretics.

It is somewhat difficult to hit the exact point of saturation between the acid and the alkali. After fourteen parts of strong distilled vinegar have been gradually poured upon one part of the salt, the addition of a little more of the acid will occasion no further effervescence while the mixture is cold; but if well heated and stirred the effervescence begins again, and continues till four or five parts of fresh acid have been added: on exhaling the aqueous fluid, the remaining dry salt will generally still raise an effervescence with fresh vinegar, and require two or three parts more of the acid to render it completely neutral. There is therefore, this advantage, in reducing the salt to a dry form, that the perfect neutralization can be obtained with greater certainty than when the ingredients are barely mixed together. The purification

cation of the dry salt, or separation of its oil, renders it fitter for weak stomachs, on which it would not sit so easily in its impure state; though the medicine, thus purified, is in some particular cases less to be depended upon than the oily salt.

Combinations of vinegar with volatile alkaline salts, commonly made with distilled vinegar added gradually to the salt till the effervescence ceases, have little purgative virtue, but operate powerfully as aperients; by urine if the patient walks about in the cool air, by perspiration or sweat, if kept warm in bed. They are principally made use of in this last intention: and as they act without any sensible irritation, they have place in inflammatory cases, where the warm sudorifics, if they fail of exciting a sweat, aggravate the distemper. The common dose of these solutions is half an ounce.

There are also medicated vinegars, as vinegar of antimony, of elder, litharge, roses, squills, treacle, &c. which derive their chief virtues from vinegar.

VINEYARD, a plantation of vines. See VINE.

VINI *Oleum*, oil of wine, a very precious liquid, kept as a secret in the hands of some dealers in spirits, and used to give the brandy flavour to spirits of less price. It is certain, that all the spirits we use take their flavour from the essential oil of the substance they are made from; that of malt is very nauseous and offensive, and renders the spirit horribly disagreeable, if not carefully kept back in the distillation of it; that of the grape, on the other hand, is extremely agreeable, and is what gives the delicious flavour to French brandy; this, therefore, is to be carefully brought over among the spirit in distillation.

This is that oil of wine so much celebrated among our distillers, and is for their use made separate, being of such effect, that half an ounce of it will determine a pure and clear malt spirit to be French brandy, so as to stand the test of the nicest palate, and all the trials that can be invented, provided the oil and the spirit have both been carefully made.

The manner of making the oil is this: they take the cakes of dry wine lees, such as are used by our hatters, and dissolving them in six or eight times their weight of water, they distil the liquor with a slow fire, and separate the oil by the separating glass, reserving for this nice use only that which comes over first, the oil that follows being coarser and more resinous. To render this business perfectly successful, there must be several things observed: First, the lee must be of the right kind, that is, of the same nature with the French brandy proposed to be imitated. Secondly, The malt spirit must be extremely pure. Thirdly, the dose of the oil must be very well proportioned: and, fourthly, the whole must be artificially united into one simple and homogeneous liquor. These cautions all regard only the taste; and besides these, in order to come up to a nice counterfeit, several other particulars must be attended to; such as the colour, proof, tenacity, softness, and the like; so that, in short, the operation has too much nicety in it to be hit off by every ordinary dealer. When this fine oil of wine is procured, it may be mixed into a quintessence, with pure distilled alcohol, or the totally inflammable spirit of wine, to prevent its growing distasteful, rancid, or resinous; and thus it may be long preserved in full possession of its flavour and virtues.

The still bottoms, or remaining matter after the distillation of this oil, will yield many productions to advantage, particularly tartar, and salt of tartar, as also an empyreumatic oil, and a volatile salt, like that of animals. Some kinds of lees afford all these in much greater quantity than others; the lees of canary and mountain wines yield very little of them, and, indeed, scarce any tartar or fixed salt at all; but the white French lees of those thin wines, that afford the ordinary brandies, yield them all very copiously, insomuch that sometimes a single hoghead of dry and close-pressed lees will afford, by this process, three gallons of this oil, forty pounds of clean tartar, a large proportion of empyreumatic oil, and volatile salt, besides full four pounds of good salt of tartar. It is not to be expected, however, that every parcel of this lee should yield fully in this proportion. *Shaw's Essay on Distillery.*

VINOUS, *Vinosus*, something that relates to wine, or has the taste and smell thereof.

All vegetables, by a due treatment, afford a vinous liquor; as corn, pulse, nuts, apples, grapes, &c.

All sorts of vinous and fermented liquors, both before and after the fermentation, consist not of similar, but heterogeneous parts, which are joined together in one certain and determinate order; thus, the action of fermentation being a separation and destruction of the former connection of the subject, and transposing its parts anew, there must of necessity have been a kind of firm or durable texture in the subject so disjoined, separated, and new ranged. For example:

Grapes laid up on dry straw, in a cold place, will, for some time after they are separated from the vine, preserve that texture which gives them their saline, unctuous, and slimy sweetness; which the juice also retains after pressing, and becomes a clear and transparent must, without separating itself into parts, but continuing regularly and uniformly mixed, so as to preserve the different matters it consists of intimately connected among themselves. In this firmly connected state they may be kept many months, if a cask be filled with this juice, and set in a cool place, as we evidently see in itum. *Shaw's Essay on concentrating Wines.*

Wine, in the precise chemical or philosophical notion of it, is a saline, clammy, oleaginous matter, diluted with a large proportion of water, whereby it is expended, or set at distance from itself, while the saline parts are saturated with and interspersed among the subtle earthy ones that make the sliminess; thus, they together imbibe, detain, and hold the grosser parts; besides which there are other oily parts vastly more subtle, which, by means of the highly attenuated saline portion adhering closely to them, remain as much connected with the water as the rest; and these are what we call the spirituous parts; but the connection of them all together is so strong and durable, that they move for a long time as one body, without separating, if carefully preserved. An acquaintance with the true nature, history, and effect of vinous fermentation, will fully explain and justify these positions.

If the spirituous part be once separated and drawn away from the wine by distillation, though it were immediately to be returned back to the remaining mass from whence it came, and ever so well shook again with it, the whole by no means retains its former taste, odour, and durability, but turns to a confused turbid mixture, of a different and nauseous taste, and a disagreeable smell; and, on the whole, approaches nearly to a state of vapidness.

The only objection to this general rule is, that if a new fermentation, or even but a fret be raised, when the spirit is newly joined to the remainder in the still, the spirit may be thus reinstated, and the wine rendered perfect. The process is difficult and uncertain; but a nice management, and a proper intermedium, will bring it about.

If an inflammable spirit distilled from the same, or any other wine, be put to a parcel of wine which is too saline, or not sufficiently spirituous, the bare addition, or tumultuous admixture thereof, very far from giving the fine and intimate softness of a good wine, will rather manifest its own burning acrimony and noxious flavour to the smell and taste, and will add a nauseous bitterness to the former tartness or acidity. This is an observation of Stahl's, and is allowed by Dr. Shaw to be true in general; but he observes, that, under a nice and proper management, a fine and tasteless spirit may be prepared and introduced into wines, and will, after a time, become intimately mixed with their other part, and remain absolutely undiscoverable to the taste or smell, unless by the excellency and the strength it gives. *Stahl's Schediasma de Concentrat. Vini.*

VINTAGE, a crop of wine, or what is got from the vines each season.

The word is also used for the time or season of gathering or pressing the grapes.

VINUM, a liquor or drink commonly called wine. See WINE.

VINUM,

VINUM, in medicine, *vinum medicatum*, is particularly applied to several medicated wines, that is, medicinal preparations, of which wine is the basis. The original intention of medicated wines, was for exhilarating medicines, which were to be continued for a length of time in the most familiar and agreeable form: by this means a course of remedies was complied with, notwithstanding the repugnance and aversion which the sick often manifest to those directly furnished from the shops; and hence the inferior sort of people had their medicated ales. Nevertheless, as vinous liquors are excellent for extracting the virtues of several simples, and are not fitted for keeping, they have been employed as officinal menstrua also; and substances of the greatest efficacy are trusted in this form. The most noted of these medicated wines to be met with in dispensaries, are the *vinum aleoticum*, or *aleotic wine*: *vinum amarum*, or *bitter wine*; *vinum antimoniale*, or *antimonial wine*: *vinum aromaticum*, or *aromatic wine*: *vinum chalybeatum*, *steel wine*: *vinum emeticum*, *emetic wine*: *vinum croceum*, *saffron wine*; *vinum guaiacum*, *guaiacum wine*: *vinum ipecacoanhæ*, wine of *ipecacoanha*: *vinum millepedatum*, wine of *millepedes*: *vinum Peruvianum*, wine of *Peruvian bark*; *vinum scorbuticum*, *scorbutic wine*: and *vinum viperinum*, *viper wine*.

VIOL, *Viola*, a musical instrument of the same form with the violin, and struck like that with a bow.

There are viols of divers kinds; the first, and principal, among us, is the *bass-viol*, called by the Italians, *viola-digamba*, or the *leg-viol*, because held between the legs. It is the largest of all, and is mounted with six strings: its neck is divided in half notes by seven frets fixed thereon; its sound is very deep, soft, and agreeable.

The tablature, or music for the *bass-viol*, is laid down on six lines or rules. What the Italians call *alto viola*, is the counter-tenor of this; and their *tenore viola*, the tenor. They sometimes call it simply the *viol*: some authors will have it the *lyra*, others the *cithara*, others the *chelys*, and others the *testudo* of the ancients.

2. The *love-viol*, *viola d'amore*, which is a kind of triple viol, or violin, having six brass or steel strings, like those of the harpsichord, ordinarily played with a bow. This yields a kind of silver sound, which is very agreeable.

3. A large viol with forty-four strings, called by the Italians, *viola di bardone*, but little known among us.

4. *Viola bastarda*, or *bastard-viol* of the Italians: not used among us. Brossard takes it to be a kind of *bass-viol*, mounted with six or seven strings, and tuned as the common one.

5. What the Italians call *viola di braccio*, *arm-viol*, or simply, *braccio*, *arm*, is an instrument answering to our counter-tenor, treble, and fifth violin.

6. Their *viola prima*, or first viol, is really our counter-tenor violin; at least, they commonly use the cliff *C sol ut* on the first line, to denote the piece intended for this instrument.

7. *Viola secunda*, is much the same with our tenor-violin, having the cliff of *C sol ut* on the second line.

8. *Viola terza*, is nearly our fifth violin, the cliff *C sol ut* on the third line.

9. *Viola quarta*, or fourth viol, is not known in England or France, though we frequently find it mentioned in the Italian composition; the cliff on the fourth line.

Lastly, their *violetta*, or little viol, is in reality our triple-viol, though strangers frequently confound the term with what has been said of the *viola prima*, *secunda*, &c. See **VIOLIN**.

VIOL, is also a term used among mariners, when a hawser, or strand-rope, is bound fast with nippers to the cable, and brought to the jeer-capstan, for the better weighing of the anchor when the main-capstan proves insufficient.

VIOLA, the violet, in botany. See **VIOLET**.

VIOLATION, the act of violating; that is, forcing a woman, or committing a rape upon her.

This term is also used, in a moral sense, for a breach or infringement of a law, ordinance, or the like; and it is also used for profanation. See the articles **RAPE**, &c.

VIOLENT, in the schools, a thing done by force; in which sense it stands opposed to spontaneous. See **SPONTANEOUS**.

A thing is said to be violent when effected by some external principle, the body that undergoes it contributing nothing thereto, but struggling against it. The schoolmen allow, that man, as being endued with reason, is capable of suffering such violence, but brute and inanimate bodies are not. See the articles **INANIMATE**, &c.

VIOLET, *Viola*, in botany, a genus of plants, whose flower consists of five ringent irregular petals, with a corniculated nectarium at the base; the stamina are five small filaments, topped with obtuse antheræ, which are sometimes connected: the fruit is an ovate trigonal obtuse capsule, having one cell, which contains many ovate seeds.

The common sweet-scented violet is so well known as to need no description; it grows in gardens, in woods, and under hedges, in many parts of England, and is easily increased by parting the roots.

The leaves and flowers are used in medicine, and sometimes the roots; the flowers are a little purgative, and the syrup made of them is common, which, when well managed, is of a beautiful colour, and an useful laxative for children.

VIOLIN, or **FIDDLE**, a musical instrument mounted with four strings, or guts, and struck or played with a bow.

The violin, like most other instruments, consists of three parts, the neck, the table, and the sound-board. At the sides are two apertures, and sometimes a third is added towards the top, shaped like a heart. Its bridge, which is below the apertures, bears up the strings which are fastened to the two extremes of the instrument, at one end of them to a screw, which stretches or loosens them at pleasure.

The style and sound of the violin is the gayest, most lively, and sprightly, of all other instruments; and hence it is, of all others, the fittest for dancing: yet there are ways of touching it which render it grave, soft and languishing, and fit for church or chamber music. It generally makes the treble or highest parts in concerts. It is tuned by fifths: its play is composed of *bass*, *counter-tenor*, *tenor*, and *treble*: each part has four-fifths, which rise to a greater seventeenth. See the article **FIFTH**, &c.

In compositions of music the violin is denoted by *V*; two *V V* denote two violins. The word *violin*, alone, stands for treble violin. When the Italians prefix *alto*, *tenore*, or *basso*, it then expresses the counter-tenor, tenor, or *bass* violin. In compositions, where there are two, three, or more different violins, they make use of *primo*, *secundo*, *terzo*, or of the characters *I^o*, *II^o*, *III^o*, or *1^o*, *2^o*, *3^o*, &c. to denote the difference.

The violin has only four strings, each of a different thickness; the smallest whereof makes the *e si mi* of the highest octave of the organ; the second, a fifth below the first, makes the *a mi la*; the third, a fifth below the second, is *d la re*; lastly, the fourth, a fifth below the third, is *ge re sol*. Most nations ordinarily use the cliff *ge re sol* on the second line, to denote the music for the violin only. In France they use the same cliff as the first line at bottom. The first of these methods is best where the song goes very low; the second, where it goes very high.

VIOLONCELLO of the Italians is properly our fifth violin; which is a little *bass-violin*, half the size of the common *bass-violin*, and its strings just half as thick and half as long, which renders the sound just an octave higher than the same.

VIOLONE, in music, a double *bass*, almost twice as big as the common *bass-violin*, and the strings bigger and longer in proportion, and consequently its sound an octave lower than that of our *bass-violin*, which has a noble effect in great concerts.

VIPER, a species of serpent, common to most parts of the world. This is by far the most noxious animal of the serpent kind, that our part of the world affords; and it is as much the most useful in medicine. Indeed, ballancing

ballancing the good we receive from it, and the mischief known to be done by it, it seems far more our interest that such a creature should be among us.

The viper is a serpent usually between two and three feet in length, when at its full growth, and about an inch or usually less in thickness. The colour in the male is generally more brown and dusky than in the female; but, in both, there runs down the whole back, from the head to the tail, an undulated and broad black line; this is properly a chain of black spots, of a rhomboidal figure, inserted into each other at the ends; and by their prominent angles, and the depressions between, forming the indented line that terminates the edge of the row of figures sideways. A little below this broad line, there is on each side a series of black spots disposed regularly along; and below these, near the belly, there is on each side a line of small whitish spots, and another of larger and blackish ones; and, finally, under this there is still another row of small white spots. The belly is covered with long and narrow black scales placed transversely; the tail is not so long as in many other serpents; it is not carried to more than one fifth part of the length of the body beyond the anus, and it terminates in an extremely sharp point. This smallness of the tail is one of the most obvious characters of the viper; the colours are not perfectly certain or regular; the belly indeed in all vipers is black, and the distribution of the lines and spots, where they are any thing distinct, is always as just mentioned; but the intermediate colour of the body, which may be called the general colour, is very variable; in some it is of a pale brown, in some an iron colour; in some it has a faint cast of yellow, in some of green, and in others of a pale whitish. Some vipers have the general colour so near that of the variegations, that they are scarce distinguishable; and there have some been met with absolutely black, but these are more rare. The poison of the viper is situated wholly in its mouth, in which, beside the common rows of teeth, each viper, as well male as female, has on each side a phang or long dens caninus, which is hollowed at the base, and has about the root a bag of poisonous liquor, secreted from a peculiar gland destined to that purpose, and opening by a duct into the bottom of the bag. When the creature inflicts a wound, it is with these long teeth, and there is always discharged into it a quantity of the poisonous juice, secreted for that purpose in the bag just mentioned. The eyes of the viper are small, and its tongue forked; it darts this out with great violence, when provoked.

The viper is of the number of viviparous serpents, according to the common distinction, not laying its eggs in a dunghil or other warm places, as the common serpent and most others do, but retaining them in its body till hatched, and excluding the living young ones. Its food is principally of the animal kind; there are authors who speak of its eating herbs, but on dissecting vipers, there are generally found in their stomach the wings of beetles, the leg bones of mice, and sometimes whole mice, frogs, and other animals of the like size; which, considering the natural smallness not only of the throat, but of the whole neck of the viper, it is amazing to conceive in what manner it goes down. The method indeed is by suction, and is very slow; the creature's body being drawn out into the utmost possible thinness, and the viper's neck distending gradually at the same time, till between both it is managed. What greatly facilitates this to the viper and to all the serpent kind, for it is common to them all, is, that there is no danger of suffocation for want of breath from it, though the whole cavity of the throat be filled up; for, tho' these creatures have lungs and respiration, yet, it is not of the nature of ours, or of that of quadrupeds; they are not under a necessity of taking in and discharging a quantity of air, at quick intervals, as we are; but what they have once taken in they retain a long while, so that they are under no necessity of breathing during this operation, which is therefore not painful to them, as we might naturally imagine, but pleasant.

It is not easy to see the viper thus employed, because, after taken, it will scarce be brought to eat at all; we have indeed no instance of any thing of the serpent kind

eating while in confinement, except a female viper big with young; and, if possessed of such a one, it may be possible to be a witness to it, and to the strange terror of any little animal proper for its preying on, on being thrown in its way. Whoever has an opportunity of throwing a mouse to a viper in this condition, will see how much foundation there is for the stories of the rattlesnake, and other serpents enchanting, as it is called, the creatures they are to prey upon, in their mouths.

The viper is common in England, but much more so in the warmer countries, and there more mischievous. We may find vipers in the heat of the day, on the dry banks under hedges exposed to the sun, and in places not too much frequented almost at any time in the hotter months: in winter they retire into holes, and lie torpid the whole cold season.—However mischievous the bite of the viper is, its flesh is safe and wholesome; indeed, there is no part of it will do any harm, except the poison lodged in the wound made by the bite; this very poison separated from the bag, diluted with any liquor and swallowed, not being capable of producing any bad consequence.

The bite is attended with very terrible symptoms, and in the hotter countries is often fatal; with us many have escaped with life, without the assistance of medicines, some in spite of bad management; we have lately had the famous remedy of the people who deal in them, and must be often bit by them, explained to us. It is no more than common oil, which is to be rubbed on the wounded part over some hot coals, and repeated occasionally. With the assistance of this we have seen people escape after very terrible symptoms, such as perhaps we have not had an opportunity of seeing any body under, who did not use the same means for relief. Other more painful methods have been prescribed, but they are now wholly out of use. These were the making strong ligatures on the limb above the wound, then scarifying and burning it with a hot iron, or making a large incision, and filling it with gun-powder, and setting them on fire.

Vipers are best taken for medicinal use in the months of July and August; they are then most vigorous and fattest, though those which are taken in spring, as soon as they come out of their winter's torpid state, are always found to be in very good case; they are best for use, when first taken; but the people who sell them will never tell the truth on this head. They keep them alive in large chests, in which they will live a year or more without eating any thing.

Vipers are to be chosen large and vigorous; if intended for use while fresh, they should be killed immediately before the time, for their flesh corrupts very soon. If for drying, they should be killed at home, and after skinning hung up. Those who buy them ready dried, often have common snakes instead of vipers, and frequently such as have died of themselves in confinement.

Vipers distilled in a retort yield first a moderate quantity of a limpid phlegm, insipid, and with very little smell; after this comes over a phlegm loaded with volatile salt, a small quantity of a black and extremely foetid oil; a large quantity of a volatile salt in the mean time concreting and fixing itself in a dry form to the sides of the receiver.

The ancients were very well acquainted with the viper; they called it echis and echidna; they had many fanciful and foolish stories about it, one of which was, that the young ones always destroyed the parent animal by gnawing their way out of her body; and this is believed by many to this day, though without the least foundation in truth. They imagined also that it fed on scorpions, cantharides, and other fatal and poisonous animals, and that by that means its own poison became so very fatal.

Many of the ancients, notwithstanding all the mischief they dreaded from the viper, esteemed it sacred, and on medals its image is frequently used as a symbol of divine power. And, in the East Indies, princes have erected buildings for their entertainment, and have made it a capital crime to kill them. It is so certain that the poison of the viper is wholly in the yellowish fluid lodged

at the base of the tooth, that, when that was taken away, creatures have been bitten by the viper, and suffered no harm; the poison of this bag is separated from the blood by a conglomerated gland, lying in the lateral anterior part of the os sincipitis behind the orbit of the eye, from which gland there is a duct that conveys it into the bag at the root of the teeth. The teeth are hollowed in their lower part for the reception of this poison, and the cavity is extended upwards for the conveyance of it, though not to the very top, as some have supposed. It terminates in a long and narrow slit below the point out of which the poison is emitted into the wound. Galen tells us of people who would stop up the apertures of the teeth with a kind of paste, and then suffer themselves to be bit by the creature and receive no harm from it; but it is much more likely they imposed on people, and were bitten by other serpents that had no poison at all.

The poisonous liquor, taken from the bag and examined by the microscope, appears to be composed of minute spiculæ, or darts resembling the threads of a spider's web, but much finer; mixed with syrup of violets, it turns it reddish, so that it is evidently an acid, not, as many have supposed, an alcali. It is amazing that so small a quantity as is received of this poison into the blood, should be capable of producing such wonderful and terrible effects.

A violent pain is first felt about the wound, then a swelling, red at first, but soon after livid, extending itself very quick to the other parts; then faintness, a quick, low, and often uninterrupted pulse, convulsive vomiting of bilious matter, cold sweats; and, if death does not succeed these, the swelling continues some time, the wound becomes a foul ulcer, and the skin is usually discoloured for a long time after.

The ancients knew well enough the nature of the viper, to be convinced that its flesh was not poisonous; they ate vipers and esteemed them, as they truly are, nutritive, restorative, and cordial; the best way to feed on vipers is to cut them into pieces and boil them in chicken broth; they give it no disagreeable taste, though they communicate to it all their restorative virtues.

Dried or powdered, they are given twenty or thirty grains for a dose; but this way they lose the greater part of their virtues. The volatile salt is a noble sudorific. Its dose is from three to eight or ten grains. The oil is recommended to discuss tumours, and to be held to the nose of people in hysteric fits; but it is so very foetid, that it is now wholly out of use.

VIRAGO, a woman of extraordinary stature and courage; and who, with the female sex, has the mien and air of a man, and performs the actions and exercises of men.

VIRGA, a yard. See **YARD**.

VIRGA is particularly used in law for a verge, or rod, such as sheriffs and bailiffs carry as a badge of their office.

VIRGÆ, in physiology, a meteor called also columellæ and funes tentorii; being an assemblage of several streams of light, representing a bundle of rods or ropes. It is supposed owing to the streaming of the sun's beams through certain rimulæ, or chinks, at least through the more lax and open parts of a watery cloud, happening chiefly in the morning and evening. There is also another kind, consisting not of streams of mere white light, but, as it were, painted of various colours like those of the rainbow.

VIRGIN, *Virgo*, a female who has had no carnal commerce with man; or more properly, who has still the flos virginis or maidenhead.

In the ancient christian church, there was a kind of religious order, consisting of women, who made open and public profession of virginity; and this before the monastic life or name was known in the world. This appears from the writings of Cyprian and Tertullian, who speak of virgins dedicating themselves to Christ, before there were any monasteries to receive them. These, for distinction sake, are sometimes called Ecclesiastical virgins; and canonicæ, because they were enrolled in the canon, or matricula, of the church. They differed from

the monastic virgins chiefly in this, that they lived privately in their father's houses, and in cases of necessity, were maintained by the church; whereas the others lived in community, and upon their own labour.

Whether they made any solemn vow, is not agreed among learned writers. Cyprian thinks, their profession of virginity was not so strict, but they might afterwards marry, if they could not, or would not, persevere. But, in the following ages, the censures of the church were inflicted on such of them as broke thro' their profession. The council of Ancyra enjoins them a year's penance: the council of Chalcedon excommunicates them. However, there never was any ecclesiastical decree for rescinding, or pronouncing null, such marriages.

As to the consecration of virgins, it was usually performed publicly in the church by the bishop, or some presbyter deputed by him. When a virgin had signified her purpose to the bishop, she came and made open profession thereof in the church, and then the bishop, or his substitute, put upon her the accustomed habit of sacred virgins. One part of this habit was the sacrum velamen, or veil: another was, a purple and golden mitre, or crown, which they wore on their heads as a badge of distinction. The ordo Romanus has a long form of prayer, and the ceremony of a ring and bracelet, at their consecration: but the ancient liturgies having nothing of this, their silence seems to be an argument against the antiquity of them.

It is to be observed, that the sacred virgins were not consecrated to any special offices in the church, as the deaconesses were. However, they were in great esteem; and had particular honours paid them. They were exempt from the same taxes as the clergy were. Their persons were sacred, and there were very severe laws against any who offered the least violence to them. Constantine charged his own exchequer with their maintenance; and his mother Helena used to entertain them, and wait upon them at her own table. The church gave them a share of her own revenues, and assigned them a particular place or apartment in the house of God, whither the most noble and religious matrons used to resort, to receive their salutations and embraces.

VIRGIN is also applied figuratively to several things that retain their absolute purity, and have never been made use of. Thus virgin-wax is that which has never been wrought, but remains as it came out of the hive. Virgin-oil is that which oozes spontaneously out of the olive, &c. without pressing. Virgin-gold, is that metal such as it is found pure in the mine, without any mixture of alloy; in which state it is sometimes so soft that it will take the impression of a seal. Virgin-copper is a native copper found in the mine, and which has never been melted down. Virgin quick-silver is that found perfectly formed and fluid in the veins of mines; or at least such as is got from the mineral earth by mere lotion, without fire. Virgin-parchment is that made of the skin of an abortive lamb, &c. See **WAX**, **OIL**, &c.

VIRGIN'S-THREAD, a sort of meteor that flies in the air like small untwisted silk; which falling upon the ground, or upon plants, changes itself into a substance like a spider's web. In these northern climates it is most frequent in summer, the days being then temperately warm, the earth not exceeding dry, nor yet overcharged with moisture. This has formerly passed for a sort of dew of an earthy slimy nature: but naturalists are now agreed that the virgin's threads are no other than so many spiders webs.

VIRGINITY, *Virginitas*, the test or criterion of a virgin, or that which intitles her to the denomination. The physicians, both ancient and modern, are exceedingly divided upon the subject of virginity, some holding that there are no certain marks or testimonies thereof, and others, that there are. Moses established a test, that was to be conclusive among the Jews. The nuptial sheets, it seems, were to be viewed by the relations on both sides, and the maid's parents were to preserve them as a token of her virginity, to be produced in case her husband should ever reproach her on that score. In case the token of virginity was not found thereon, the

was to be stoned to death at her father's door. This test of virginity has occasioned abundance of speculation about the parts concerned; but the nicest enquiries cannot settle any thing certain about them. Dr. Drake says expressly, that whatever might be expected among the Jews, there is not the same reason to expect those tokens of virginity in these countries; for, besides that the Hebrews married extremely young, as is the custom in all the Eastern countries, there are several circumstances which may here frustrate such expectations, even in virgins not vitiated, either by any male contact, or any wantonness of their own. In effect, in these northern countries, the inclemency of the air exposes the sex to such checks of perspiration, as gives a great turn to the course of the humours, and drives so much humidity through the parts, as may extraordinarily supple and relax those membranes from which the resistance is expected, and from which, in hotter countries, it might more reasonably be depended on.

What most commonly passes among us for a test of virginity, is the hymen; and yet the most curious among the anatomists are greatly divided, not only about the figure, substance, place, and perforations of this membrane, but even about the existence thereof; some positively affirming, and others as flatly denying it. See **HYMEN**.

VIRGO, in astronomy, one of the signs or constellations of the zodiac, and the sixth according to order.

It is marked thus ♍, and in Ptolemy's catalogue consists of 32 stars, in Tycho's of 39, and in the British of 89.

VIRGULA DIVINA; or **BACULUS DIVINATORIUS**, &c. a forked branch, in the form of a Y, cut off a hazle stick, by means whereof people have pretended to discover mines, springs, &c. under ground.

The method of using it is thus: the person who bears it, walking very slowly over the places where he suspects mines or springs may be, the effluvia exhaling from the metals, or vapour from the water, impregnating the wood, makes it dip or incline, which is the sign of a discovery.

Some dispute the matter of fact, and deny it to be possible. Others, convinced by the great number of experiments alledged in its behalf, look out for the natural causes thereof: the corpuscles, say those authors, rising from the springs or minerals, entering the rod, determine it to bow down, in order to render it parallel to the vertical lines which the effluvia describe in their rise.

VIRGULTUM, in our ancient law books, is used for a holt or a plantation of twigs or osiers. See the article **OSIERS**.

VIRILE, something that belongs or is peculiar to a man, or the male sex: thus the virile member is used for the penis; virile age, the strength and vigour of a man's age, viz. from thirty to forty-five years, being the age wherein we are equally removed from the extremes of youth and of old age.

VIRILIA, a man's genitals, or privy members, including the penis and testes. See the articles **PENIS** and **TESTES**.

VIRTSUNGIANUS DUCTUS, in anatomy, a canal usually called ductus pancreaticus.

VIRTUAL, or **POTENTIAL**, something that has a power or virtue of acting or doing. The term is chiefly understood of something that acts by a secret invisible cause, in opposition to actual and sensible.

VIRTUAL FOCUS, in optics. See **FOCUS**.

VIRTUALITY, in the schools, denotes some mode or analogy in an object, which, in reality, is the same with some other mode, but, out of regard to contradictory predicates, is considered as if distinct therefrom.

VIRTUALLY, in the schools, is applied to a mode of existence. A thing is said to be virtually any where, when it is deemed to be there by some virtue, influence, or other effect, produced by it: thus the sun is virtually on earth, i. e. by his light, heat, &c. A thing is also said to be virtually present, when the virtues or proper-

ties belonging to it, and issuing from it, remain: in which sense the forms of the elements are held to be virtually in mixed bodies. A thing is said to be a cause virtually, or a virtual cause, and that two ways; the first, when there is no real distinction between it, and the effect attributed to it, and yet it is conceived by us, as if it were really the cause thereof: thus immutability in God, is the cause of eternity. Secondly, when an effect is not of the same kind with the cause, and yet the cause has the power or virtue of producing the effect; thus the sun is not formally but virtually hot; and the fire is not contained formally but virtually in heat.

VIRTUE, *Virtus*, a term used in various significations. In the general it denotes power, or perfection of any thing, whether natural or supernatural, animate or inanimate, essential or accessory. But in its more proper or restrained sense, virtue signifies an habit, which improves and perfects the possessor and his actions.

In this sense virtue is a principle of acting or doing well and readily, and that either infused from above, such as are the theological virtues; or acquired by our own application, as the intellectual or moral virtues.

For as there are two things in man, from which all his actions proceed, viz. the understanding and the will; so the virtue by which he is perfected, or whereby he is disposed to do all things rightly, and to live happily, must be twofold: the one of the understanding, and the other of the will. That which improves the understanding is called intellectual, or dia-noetic; and that, the will, moral and ethic; for since there are two things required, in order to live aright, viz. to know what should be done, and, when known, readily to perform it; and since man is apt to err various ways in each respect, unless regulated by discipline, &c. he alone can deport himself rightly in his whole course of life, whose understanding and will have obtained their utmost perfection.

Intellectual virtue, then, according to Aristotle, is an habit of the reasonable soul, whereby it conceives or speaks the truth, either in affirming or denying. The virtues which come under this class are divided into speculative, which are those conversant about necessary things, that can only be known or contemplated; and practical, which are conversant about contingent things, that may likewise be practised. Aristotle has another division of intellectual virtues, fetched from the subject, as some of them are seated in the contemplative part, viz. those conversant about necessary things, as science, wisdom, intelligence; and others in the practical part, such as those conversant about contingent things, as prudence, art, &c.

Moral virtue is defined, by Aristotle, to be an elective habit, placed in a mediocrity, determined by reason, and as a prudent man would determine. Moralists usually distinguish four principal, or, as they are vulgarly called, cardinal virtues, viz. prudence, justice, fortitude, and temperance: the reason of which division is founded in this, that for a man to live virtuously and honestly, it is necessary he know what is fit to be done, which is the business of prudence: that he have a constant and firm will to do what he judges best; which will perfect the man, either as it restrains too violent perturbations, the office of temperance; or as it spurs and urges on those that are too slow and languid, which is the business of fortitude; or, lastly, comparatively with regard to human society, which is the object of justice. To these four virtues all the rest are referred, either as parts, or concomitants.

VIRTUES, in the celestial hierarchy, the third rank or choir of angels, being that in order between the dominations and powers: to these is attributed the power of working miracles, and of strengthening and reinforcing the inferior angels in the exercise of their functions.

VIRTUOSO, an Italian term lately introduced into English, signifying a man of curiosity and learning, or one who loves and promotes the arts and sciences; but among us the term seems to be appropriated to those who apply themselves to some curious and quaint, rather than immediately

mediately useful, art or study, as antiquaries, collectors of rarities of any kind, microscopical observers, &c.

VIRULENT, a term applied to any thing that yields a virus, that is, a contagious or malignant pus.

VIS, a Latin word, signifying force, or power; adopted by physical writers, to express divers kinds of natural powers, or faculties.

Vis Inertiæ, or power of inactivity, is defined by Sir Isaac Newton to be a power implanted in all matter, whereby it resists any change endeavoured to be made in its state, either of rest, or motion.

This power, then, coincides with the vis resistendi, power of resisting, whereby every body endeavours, as much as it can, to persevere in its own state, whether of rest, or uniform rectilinear motion: which power is still proportional to the body, and only differs from the vis inertiae of the mass, in the manner of conceiving it.

Bodies only exert this power, in changes brought on their state by some vis impressa, force impressed on them. — And the exercise of this power, is, in different respects, both resistance, and impetus: resistance, as the body opposes a force, impressed on it to change its state; and impetus, as the same body endeavours to change the state of the resisting obstacle.

Vis Impressa, is defined by Sir Isaac Newton, to be the action exercised on any body, to change its state, either of resisting, or moving uniformly in a right line.

This force consists altogether in the action; and has no place in the body after the action is ceased. For the body perseveres in every new state, by the vis inertiae alone.

VISCERA, in anatomy, a term signifying the same with entrails, including the heart, liver, lungs, spleen, intestines, and other inward parts of the body.

Wounds of the VISCERA. — If any of the viscera situated in the abdomen, as the liver, spleen, or kidney, has received a wound from a sharp instrument, at the first dressing the wound must be filled as tenderly as possible with lint well saturated with highly rectified spirit of wine, or spirit of turpentine, securing the dressings with compresses and a bandage; by this means the hæmorrhage will be stopped, if no large vessel is divided. When this part is gained, the wound must be treated in the common manner, and the patient kept very low; bleeding him, if of a plethoric habit, and giving daily two or three doses of Locatellus's balsam; for balsams of this kind are of great service in healing internal wounds.

This is the method to be taken with wounds of the viscera, which may be discovered by the eye or touch. But in such of them as are hidden, and not to be thus discovered, all that can be done is to inject vulnerary decoctions, and keep a passage open for the evacuation of serdes, or grumous blood.

VISCIDITY, or **Viscosity**, the quality of something that is viscid or viscous, that is glutinous and sticky, like bird lime, which the Latins call by the name *viscus*. Viscid bodies are those which consist of parts so implicated within each other, that they resist a long time a complete separation; and rather give way to the violence done them, by stretching or extending every way. The too great viscosity of foods has very ill effects; thus meats or farinæ not fermented, jellies, &c. of animals, tough cheese, or curds too much pressed, produce weight or oppression in the stomach, wind, yawnings, crudities, obstructions of the minuter vessels in the intestines, &c. Hence an inactivity of the intestines themselves, a swelling of the abdomen; and hence a viscosity of the blood, from the re-union of the viscid particles; obstructions of the glands; paleness, coldness, tremors, &c.

VISCUM, mistletoe, in botany. See the article **MISTLETOE**.

VISIBLE, something that is an object of sight, or vision; or something whereby the eye is affected, so as to produce a sensation. See **VISION**.

The school philosophers make two kinds of visibles, or visible objects: the one proper, or adequate; which are such as are no other way perceivable, but by sight alone:

the other common, which are subject to divers senses, as the sight, hearing, feeling, &c.

Again, the first, or proper object of vision, is of two kinds, viz. light, and colour; for these two are only sensible by sight. — The first, and primary, viz. light, they make the formal, and colour the material object.

The Cartesians think they philosophize better, when they say, that light, alone, is the proper object of vision; whether it flow from a luminous body through a transparent medium, and retain its first name, light; or whether it be reflected from opaque bodies, under a certain new modification, or habitude, and exhibit their images; or, lastly, whether in being reflected, it is likewise refracted, after this, or that manner, and affects the eye with the appearance of colour.

But, agreeable to Sir Isaac Newton's sentiments, colour alone is the proper object of sight: colour being that property of light, whereby the light itself is visible, and whereby the images of opaque objects are painted on the retina.

Aristotle, *De Anima*, Lib. II. enumerates five kinds of common visibles, which are usually received for such in the schools, viz. motion, rest, number, figure, and magnitude. — Others maintain nine, as in the verses,

*Sunt objecta novem visus communia: quantum,
Inde figura, locus, sequitur distantia, situs,
Continuumque & discretum, motusque, quiesque.*

Authors reason very variously as to these common objects of vision: there are two principal opinions among the schoolmen. The adherents to the first, hold, that the common visibles produce proper representations of themselves, by some peculiar species or image, whereby they are formally perceived, independently of the proper visibles.

But the second opinion prevails most, which imports, that the common visibles have not any such formal peculiar species to become visible by: but that the proper objects are sufficient to shew themselves in this or that place or situation, and in this or that distance, figure, magnitude, &c. by the circumstances of their conveyance to the sensory.

In effect, since these common visibles cannot be represented alone, for who ever saw place, distance, figure, situation, &c. of itself, but are always conveyed along with the images of light and colour to the organ; what necessity is there to conceive any such proper images, whereby the common visibles should be formally perceived by the soul? It is much more probable that from the peculiar manner wherein the sensitive faculty perceives a proper object, it is apprised of its being in this or that situation or place, in this or that figure, magnitude, &c. How this is effected, may be conceived from what follows.

1. The situation and place of visible objects are perceived without any intentional species thereof, merely by the impulse being made from a certain place, and situation, either above, or below, on the right, or left, before, or behind; whereby the rays of the proper visibles are thrown upon the retina, and their impression is conveyed to the sensory.

For since an object is seen by those rays which carry its image to the retina, and in that place to which the visive power is directed by the rays it receives: as it perceives the impulse of the rays to come from any place, &c. it is abundantly admonished.

From this principle, several remarkable phenomena of vision are accountable for, as,

1. That if the distance between two visible objects be an angle that is insensible, the distant bodies will appear as if contiguous: whence, a continuous body being the result of several contiguous ones; if the distance between several visibles subtend insensible angles, they will appear one continuous body: which gives a pretty illustration of the notion of a continuum.

2. If the eye be placed above a horizontal plane, objects, the more remote they are, the higher they will appear, till the last be seen in a level with the eye. Whence it is, that the sea, to persons standing ashore, seems to rise higher and higher the further they look.

3. If

3. If any number of objects be placed below the eye, the most remote will appear the highest: if they be above the eye, the most remote will appear the lowest.

4. The upper parts of high objects appear to stoop, or incline forwards; as the fronts of churches, towers, &c. — And statues at the tops of buildings, to appear upright, must recline, or bend backwards.

II. The mind perceives the distance of visible objects from the different configuration of the eye, and the manner wherein the rays strike the eye, and in which the image is impressed thereon. For the eye disposes itself differently, according to the different distances it is to see, viz. for remote objects the pupil is dilated, and the crystalline brought nearer the retina, and the whole eye is made more globous; on the contrary, for near objects the pupil is contracted, the crystalline thrust forwards, and the eye lengthened.

The distance, again, is adjudged of by the angle the object makes from the distinct or confused representation of the objects, and the briskness or feebleness, or the rarity or spissitude of the rays. To this is owing, 1. That objects which appear obscure or confused, are judged to be more remote: a principle which the painters use, to make some of their figures appear farther distant than others on the same plane. To this it is likewise owing, that rooms whose walls are whitened, appear the smaller: that fields covered with snow, or white flowers, shew less than when clothed with grass: that mountains covered with snow, in the night time, appear the nearer: and that opaque bodies appear the more remote in the twilight.

III. The magnitude or quantity of visible objects, is known chiefly by the angle comprehended between two rays drawn from the two extremes of the object, to the center of the eye. An object appears so big as is the angle it subtends: or bodies seen under a greater angle appear greater; and those under a less, less, &c. Hence, the same thing appears now bigger, and now less, as it is less or more distant from the eye. This we call the apparent magnitude.

Now, to judge of the real magnitude of an object, we consider the distance: for since a near and a remote object may appear under equal angles, the distance must necessarily be estimated; that if it be great, and the optic angle small, the remote object may be judged great, and *vice versa*.

The magnitude of visible objects, is brought under certain laws, demonstrated by the mathematicians, as,

1. That the apparent magnitudes of a remote object, are as the distances reciprocally.

2. That the co tangent of half the apparent magnitudes of the same objects, are as the distances: hence, the apparent magnitude and distance being given, we have a method of determining the true magnitude: the canon is this, as the whole sine is to the tangent of half the apparent magnitude, so is the given distance to half the real magnitude. — The same canon, inverted, will, from the distance and magnitude given, determine the apparent one.

3. Objects, seen under the same angle, have their magnitudes proportional to their distance.

4. The subtense AB (plate CXXXVI. fig. 1.) of any arch of a circle, appears of equal magnitude in all the points DCEG, tho' one point be vastly nearer than another; and the diameter DG, appears of the same magnitude in all the points of the periphery of the circle. Hence we take a pretty hint for the most commodious form of theatres.

5. If the eye be fixed in A, (fig. 2.) and the right line BC be moved in such manner, as that the extremes thereof always fall on the periphery; it will always appear of the same magnitude. — Hence, the eye being placed in any angle of a regular polygon, the sides will appear equal.

6. If the magnitude of an object directly opposite to the eye, be equal to its distance from the eye, the whole object will be taken in by the eye, but nothing more. Whence, the nearer you approach an object, the less part you see of it.

IV. The figure of visible objects is estimated chiefly from our opinion of the situation of the several parts thereof,

This opinion of the situation, &c. enables the mind to apprehend an external object under this or that figure, more justly than any similitude of the images in the retina with the object can; the images being frequently elliptical, oblong, &c. when the objects they exhibit to the mind are circles, squares, &c. The laws of vision, with regard to the figures of visible objects, are,

1. That if the center of the pupil be exactly against, or in the direction of a right line, the line will appear as one point.

2. If the eye be placed in the direction of a surface, so that only one line of the perimeter can radiate on it, it will appear as a line.

3. If a body be opposed directly towards the eye, so as only one plane of the surface can radiate on it, it will appear as a surface.

4. A remote arch, viewed by an eye in the same plane, will appear as a right line.

5. A sphere, viewed at a distance, appears a circle.

6. Angular figures, at a distance, appear round.

7. If the eye look obliquely on the center of a regular figure, or a circle, the true figure will not be seen; but the circle will appear oval, &c.

V. The number of visible objects is perceived, not only by one or more images formed in the fund of the eye; but also by such a position of those parts of the brain, whence the optic nerves spring, as the mind has been used to, in attending to a certain place, and that either single, or manifold.

Accordingly, when either of the eyes, with the contiguous part of the brain, are forced out of their just parallelism with the other, *v. gr.* by pressing it with the finger, &c. all things appear double: but when they are in the requisite parallelism, though there be two images in the fund of the two eyes, yet the object will appear single. Again, one thing may appear double, or even manifold, not only with both eyes, but even with only one of them open: by reason, the common concurrence of the cones of rays, reflected from the object to the eye, either falls short of the retina, or goes much beyond it.

VI. Motion and rest are seen, when the images of objects represented in the eye, and propagated to the brain, are either moved, or at rest; and the mind perceives these images either moving or at rest, by comparing the moved image to another with respect to which it changes place: or, by the situation of the eye to the object being continually changed. So that motion is only perceived, by perceiving the images to be in different places and situations: nor are these changes perceived, unless effected in time. So that to perceive motion, a sensible time is required. — But rest is perceived by the visual faculty, from the perception of the image in the same place of the retina, and the same situation, for some sensible time.

Hence the reason, why bodies moving exceeding fast appear at rest: thus, a live coal, swung briskly round appears a continued circle of fire; the motion not being commensurate with visible time, but much swifter than the same: so that in the time the soul requires to judge of any change of situation of the image on the retina, or that it is moved from this place to that, the thing itself performs its whole circuit, and is in its former place again.

Laws of vision with regard to the motion of visibles, are — 1. That if two objects, unequally distant from the eye, move from it with equal velocity; the more remote one will appear the slower: or, if the celerities be proportionable to their distances, they will appear to move equally swift.

2. If two objects, unequally distant from the eye, move with unequal velocities in the same direction, their apparent velocities are in a ratio compounded of the direct ratio's of their true velocities, and the reciprocal one of their distances from the eye.

3. A visible object, moving with any velocity, appears to be at rest, if the space described in the interval of one second be imperceptible at the distance of the eye. Hence it is, that a near object, moving very slowly, as the index of a clock, or a remote one very swiftly, as a planet, seem at rest.

Visible.

Fig. 3.

operation for the Unguis.

4. An object, moving with any degree of velocity, will appear to rest, if the space it runs over in a second of time be to its distance from the eye, as 1 to 1400 : nay, in fact, if it be as 1 to 1300.

5. The eye proceeding straight, from one place to another, a lateral object, either on the right or left, will seem to move the contrary way.

6. If the eye and the object move both the same way, only the eye much swifter than the object, that last will appear to go backward,

7. If two or more objects move with the same velocity, and a third remain at rest, the moveables will appear fixed, and the quiescent in motion the contrary way. Thus, clouds moving very swiftly, their parts seem to preserve their situation, and the moon to move the contrary way.

If the eye be moved with a great velocity, lateral objects at rest appear to move the contrary way. — Thus, to a person, sitting in a coach, and riding briskly thro' a wood, the trees seem to retire the contrary way; and to people in a ship, &c. the shores seem to recede.

VISI^{ER}, or VIZI^{ER}, an officer or dignitary in the Ottoman empire, of which there are two kinds; the first called by the Turks visier-azem, that is, grand visier, is the prime minister of state of the whole empire. He commands the army in chief, and presides in the divan or great council. Next to him are six other subordinate visiers, called visiers of the bench, who officiate as his counsellors, or assessors in the divan.

VISION, *Visio*, in optics, the act of seeing or perceiving external objects, by means of the organ of sight, the eye. See EYE.

Such is the substance and form of the humours of the eye, when lodged in their proper receptacles, that rays of light in passing through them, are affected in like manner as in passing through a convex lens; and therefore, to understand perfectly the nature of vision, we must first be acquainted with the doctrine of light and lenses. See LIGHT and LENS.

Now as the several pencils of rays flowing from the distinct points in the surface of an object placed before a lens, are collected into so many points at a certain distance on the other side of the lens, and form an image there, when received upon paper; so pencils of rays proceeding from an object placed before the eye at a proper distance from it, and being refracted in passing thro' the humours of it, are collected into their respective foci upon the retina, where they form a representation of that object; and by their impulses upon the tender nerves of the retina, an idea of the object is excited in the mind. See REFRACTION.

Vision is distinguished into bright and obscure, distinct and confused. It is said to be bright when a sufficient number of rays enter the pupil at the same time; and obscure, when too few; it is called distinct when each pencil of rays is collected into a focus exactly upon the retina; and confused, when they meet before they come at it, or when they would pass it before they meet.

Now since parallel rays only have their focus upon, or meet in, the retina, they alone can paint there a distinct image of an object, or produce a distinct vision of it. If therefore, the object be so near, that the rays from any particular point come diverging to the pupil, they will necessarily require a greater focal distance than the retina or bottom of the eye; whence the rays not being united upon the retina, that point cannot be there distinctly represented, but will appear confused: thus, AB, A B (plate CXXXVI. fig. 3.) are two parallel rays falling upon the pupil of the eye; and CB, CB, two other rays, which though really diverging, yet, by reason of the remoteness of the point C, whence they proceed, will at the entrance of the eye be so nearly coincident with the parallel rays, as to have nearly the same focal point on the retina, so that the point C will there be distinctly represented by c. But if any other point E, be viewed very near the eye, so that the angles EBA, which they contain with the parallel rays, be very considerable, they will, after refraction, tend towards the point f, in the axis of the eye produced, and upon the retina will represent only a circular indistinct area; like that at

e, whose breadth is equal to *ab*, the distance of the rays upon the retina. The same point at D, will not be quite so much dilated, as the rays DB, DB, have a less degree of divergence.

It is found by experience, that the nearest limit of distinct vision, is about six inches from the eye; for if a book be held nearer to the eye than that, the letters and lines will immediately become confused and indistinct. Now this cause of indistinct vision may be in some measure remedied, by lessening the pupils, which we naturally do in looking at near objects, by contracting the annular fibres of the uvea; and artificially, by looking through a small hole made with a pin in a card, &c. for then a small print may be read much nearer than otherwise: the reason is plain, for the less the diameter of the aperture or pupil BB, the less will the rays diverge in coming from D or E, or the more nearly will they coincide with parallel rays.

Besides the contraction of the pupil, nature has furnished the eye with a faculty of adapting the conformation of the several parts to the respective positions of objects, as they are nigh or more remote; for this purpose the cornea is of an elastic yielding substance, and the crystalline is inclosed with a little water in its capsula, that by the contraction and relaxation of the ciliary ligament, the convexity of both the surfaces of the capsula may be a little altered, and perhaps the position of the crystalline; by which means the distance from the retina may be fitted and adjusted to nigh objects, so as to have their images very distinctly formed upon the retina.

Nigh objects only have been mentioned, by which are meant such as are near the limit of distinct vision, as between six and a hundred inches distance, because remoter objects require scarce any change of the conformation of the eye; the focal distance in them varying so very little. Thus, suppose all the refraction of the eye were equivalent to that of a double and equally convex lens, whose radius $r = 1$ inch: if then the object were 10 inches distant or $d = 10$, we should have the focal distance

$$f = \frac{dr}{d-r} = \frac{10}{9} = 0.11111; \text{ and if another object be}$$

$$\text{distant 100 inches, then } d = 100, \text{ and } f = \frac{dr}{d-r} = \frac{100}{99} = 0.10101.$$

The difference between these two focal distances is 0.0101, viz. something more than the hundredth part of an inch, which the eye can easily provide against. If we go beyond this, suppose to an object 1000

$$\text{inches distant, we have } f = \frac{dr}{d-r} = 0.1001001, \text{ which is}$$

only the thousandth part of an inch less than the former, and is therefore inconsiderable.

Now, rays proceeding from any point, more than 6 inches distant from the eye, will, when they enter the pupil, be very nearly coincident with parallel rays; and therefore, to a sound eye, distinct vision cannot be effected at less than 6 or 8 inches distance, as may be found by any one who will make the experiment.

Six inches, therefore, constitutes the limit of distinct vision, for near objects: we shall now consider the limit for remote objects; for objects may appear indistinct and confused, by being removed too far from the eye, as well as when they are too near it. And in this case, we find objects will appear distinct so long as their parts are separate and distinct in the image formed on the retina; and those parts will be separate so long as the axis of the pencils of rays, which paint them, are separate at their incidence on the retina; that is, so long as the angle they contain is not less than one-tenth of a degree: for it is found, by experience, that objects and their parts become indistinct, when the angle they subtend at the pupil of the eye is less than that quantity.

Thus, suppose OB (fig. 4.) to be a circle one-tenth of an inch in diameter, it will appear distinct with its central spot, till you recede to the distance of 6 feet from it, and then it becomes confused; and if it be one-fifth of an inch, it will begin to be confused at 12 feet distance, and so on; in which cases, the angle subtended at the eye, viz. OAB, is about one-tenth of a degree, or 6 minutes.

And thus all objects, as they are bigger, appear distinct at a greater distance; a small print will become confused at a less distance than a larger; and in a map of England, the names of places in small letters become first indistinct, where those in capitals are very plain and legible; at a bigger distance these become confused, while the several counties appear well defined to a much greater distance: these also at last become so indistinct as not to be known one from another, when at the same time the whole island preserves its form very distinctly to a great distance; which may be so far increased, that it also, at last, will appear but a confused and unmeaning spot.

We have seen the causes of indistinct vision in the objects, and shall now enquire what may produce the same in the eye itself.

And first it is to be observed, that there is a proper degree of convexity in the cornea K P L (*fig. 5.*) and crystalline S T, for converging parallel rays to a focus on the bottom of the eye, in a sound state; hence every distant object O B, will have its image I M, accurately depicted on the retina, and by that means produce distinct vision.

But if the cornea K P L (*fig. 6.*) or crystalline S T, or both, should chance to be a little more convex than just, it will cause the pencil of rays $o C o$, which comes to the pupil $o o$, from any point C in the object O B, to unite in a focus before they arrive at the retina in the bottom of the eye; the image I M, of the object O B, will be formed in the body of the vitreous humour, and will therefore be very confused and indistinct on the retina at $i m$. A person having such an eye, is called myops, in allusion to the eye of a mouse, by reason of its great convexity. To remedy this defect of the eye, a concave lens E F is applied before it; for, by this means the rays C a, C b, which fall diverging on the lens, will, after reflection through it, be made to proceed still more diverging, viz. in the directions $a r$, $b r$, instead of $a o$, $b o$, as if they came from the point c instead of C. Hence it follows, that since the rays are made to fall with greater divergence upon the eye, they will require a greater focal distance to be united in the axis; and, consequently, the focus may be made to fall very nicely on the retina, by using a lens E F, of a proper degree of concavity; so that distinct vision will be effected, in the same manner as in an eye of a just conformation.

Since the point c , is nearer to the eye than the point C, the apparent place of objects seen through a concave lens is nearer than the true place; or the object will appear at O B, instead of O B; and also, since converging rays O a, B b, proceed less converging after refraction than before, the object appears under a less angle; and, therefore, the apparent magnitude of objects, seen by a concave lens, is less than the true: the object is also less luminous or bright, seen thro' such a lens, than without it; because the rays being rendered more divergent, a less quantity enters the pupil of the eye, than otherwise would do: for the picture is always more or less bright, according as it is made by a greater or less quantity of rays. Lastly, it appears from what has been said, that when a concave lens E F, cannot be applied, we may still effect distinct vision, by lessening the distance between the object and the eye: for it is plain, if O B be situated at O B, the image I M, will recede to $i m$, upon the retina, and be distinct, in the same manner as when made so by the lens E F.

On the other hand, when the cornea or crystalline is too flat, &c. (as often happens by age) an object O B (*fig. 7.*) placed at the same distance from the eye P C, as before, will have the rays C a, C b, after refraction in the eye, proceed to a focus beyond the bottom of the eye, in which if a hole were made, in an eye taken out of the head, the rays would actually go on, and form the image $i m$; which image must, therefore, be very confused and indistinct on the retina. To remedy this defect, a convex lens G H, is applied, which causes the diverging rays C a, C b, to fall less diverging upon the eye, or as if they came from a point more remote, as c ; by which means the focal distance is shortened, and the image duly formed on the retina at I M, by which distinct vision is produced.

Hence the apparent place of the object at c , is more distant than the true place is at C; and its apparent magnitude O B is greater than the true, because the converging rays O a, B b, are by this lens after refraction made to unite sooner than before, and so to contain an angle O P B greater than the true O P B. The object appears through a lens brighter than without, because by this means a greater quantity of rays enter the pupil; for the rays $a o$, $b o$, are by the lens made to enter in the directions $a r$, $b r$, which are nearer together, and leave room for more to enter the pupil all around between o and r .

As the image of the object painted on the retina is greater or less, so will the apparent magnitude of the object be likewise; or, in other words, the angle I P M (*fig. 8.*) subtended by the image is always equal to the angle O P B subtended by the object at the eye, and therefore the image I M will be always proportionable to the object O B. Hence it follows, that the angle O P B under which an object appears, is the measure of its apparent magnitude.

Therefore objects of different magnitudes, as O B, A C, D E, which subtend the same angle at the eye, have the same apparent magnitude, or form an equal image in the bottom of the eye. Hence it is that objects at a great distance have their magnitude diminished proportionally; thus the object D E removed to D E appears under a less angle D P E, and makes a less image on the retina, as is shewn by the dotted lines.

The angles of apparent magnitude O A B, O C B, (*fig. 9.*) when very small, are as their sines, and therefore as the sides O C and O A, or B C and B A; that is, the apparent magnitude of the object O B, at the distances B C and B A, is inversely as those distances; or its magnitude at C is to that at A as A B to C B.

The more directly any object is situated before the eye, the more distinctly it will appear; because those rays only which fall upon the eye near its axis can be convened to a point in the bottom of the eye on the retina, and therefore that part of the image only which is formed by the direct pencil of rays can be clear and distinct; and we are said to see an object by such a pencil of rays, but only to look at it by the others which are oblique. Suppose A, B, C, (*fig. 10.*) represent three pieces of paper stuck up against the wainscot of a room at the height of the eye; if then a person places himself so before them, and shutting his right eye views them with his left, it is very remarkable that the paper B, whose pencil of rays falls upon the insertion D of the optic nerve D E, will immediately vanish or disappear, while the two extreme papers C and A are visible; and by altering the position of the eye, and its distance, any of the papers may be made to vanish, by causing the pencil of rays to fall on the point D. Why the rays of light should not excite the sensation of vision in the point D, where the fibres of the nerves begin to separate and expand every way to form the retina, is not easy to say. But it is worth notice, that the nerve D E is for that reason placed on one side of the eye, where only the oblique rays come, the loss of which is not considerable, and no way affects or hinders the perfection of sight: whereas had it entered in the middle of the bottom of the eye, it had rendered useless all the direct rays, by which the most perfect and distinct vision is effected; and we could have had only a confused imperfect conception of objects, by oblique collateral rays.

The laws of vision, brought under mathematical demonstration, make the subject of optics, taken in the greatest latitude of the word; which is commonly used, in a more restrained sense, for the doctrine of direct or simple vision, performed by rays passing directly, or in a straight line, from the object to the eye. The doctrine of real vision, or that performed by means of rays reflected from mirrors, makes the subject of catoptrics; and refracted vision, or that performed by rays refracted thro' glass lenses, or other mediums, constitutes that branch of optics, called dioptrics.

VISION, among divines, is used for an appearance, which God occasionally sent his prophets and saints; either by way of dream, or in reality.

Such were the visions of Ezekiel, Amos, &c. the vision of St. Paul, lifted up to the third heaven, &c. of Joseph, by which he was assured of the purity of the virgin, &c.

Many among the Romish saints still pretend to visions: thus the Revelations of St. Bridget are so many visions.

Hence the word has come into disrepute, and become a common name for all chimeras, or spectres, which either our folly or fear possesses us with: and hence, a person that frames to himself wild romantic notions, is called a visionary. Quevedo's visions are descriptions of what passed in the imagination of that author.

Beatific Vision, denotes the act whereby the angels and blessed spirits see God in paradise.

VISITATION, in law, an act of jurisdiction, whereby a superior, or proper officer, visits some corporation, college, church, or other public or private house, to see that the laws and regulations thereof be duly observed.

Among us, visitation is that office performed by the bishop in every diocese once in three years, or by the archdeacon every year, by visiting the churches and their rectors throughout the whole diocese, &c. The bishop's commissary also holds a court of visitation, to which he may cite all church-wardens and sidesmen; and to whom he exhibits his articles, and makes inquiry by them.

VISUAL, in general, something belonging to vision. See **VISION**.

Thus, rays of light, coming from an object to the eye, are called visual rays; and the visual point in perspective is a point in the horizontal line, wherein all the visual rays unite. See **RAY** and **PERSPECTIVE**.

VITAL, in physiology, an appellation given to whatever ministers principally to the constituting or maintaining of life in the bodies of animals: thus, the heart, lungs, and brain are called vital parts; and those operations of these parts, whereby the life of animals is maintained, are called vital functions. See **FUNCTION**.

VITREOUS Humour of the Eye, is so called from its resemblance to glass infusion, being very like a fine clear jelly in appearance: it probably, says Heister, consists of extremely fine vesicles, containing a limpid and perfectly pellucid humour. It fills the posterior part of the eye, and is every where contiguous to the hinder part of the retina, which it serves also to expand. See the article **EYE**.

VITRIFICATION, in chemistry, is the converting a body into glass, by means of fire. See **GLASS**.

Of all bodies, fern-ashes, sand, pebbles, &c. vitrify the most readily; and accordingly, it is of these that glass is principally made.

VITRIOL, *Vitriolum*, a saline crystalline concrete, composed of metal united with a certain acid called the vitriolic acid. There are three metals with which this acid is found naturally combined, zinc, copper, and iron: with the first it forms a white, with the second a blue, and with the third a green salt.

1. White vitriol, or vitriol of zinc; found in the mines of Goslar, sometimes in transparent pieces, more commonly in white efflorescences; which are dissolved in water, and crystallized into large irregular masses, somewhat resembling fine sugar; in taste sweetish, nauseous, and styptic.

The common white vitriol of the shops contains a quantity of ferruginous matter; of which, in keeping, a part is extricated from the acid, in an ochery form, so as to tinge the mass of a yellow hue. On dissolving the whitish pieces in water, a considerable portion of ochre immediately separates: the filtered solution, transparent and colourless, becomes again turbid and yellow on being made to boil, and deposits a fresh ochery sediment; and a like separation happens, though much more slowly, on standing without heat. Hence, when the solution is evaporated to the usual pitch, and set to crystallize, the crystals generally prove foul; unless some fresh acid be added, as an ounce of the strong spirit or oil of vitriol to a pound of the salt, to keep the ferruginous matter dissolved: this addition both secures the whiteness

of the crystals, and prevents their growing soon yellow in the air. White vitriol generally contains also a small portion of copper, distinguishable by the cupreous stain which it communicates to polished iron immersed in solutions of it, or rubbed with it in a moist state. The quantity of this metal is so exceedingly minute, that it is not, perhaps, of any inconvenience in any of the intentions for which white vitriol is employed: the separation, if it should be thought necessary, may be effected, by boiling the solution for some time, along with bright pieces of iron, which will extricate all the copper; by continued or repeated coction, greatest part of the ferruginous matter also may be separated.

White vitriol is sometimes given, from five or six grains to half a dram or more, as an emetic; and appears to be one of the quickest in operation of those that can be used with safety. Externally, it is employed as a cooling restraining and desiccative: a dilute solution of it, of a dram for instance in a pint of water, is an excellent collyrium in defluxions and slight inflammations of the eyes, and, after bleeding and purging, in the more violent ones: a solution of it with alum, in the proportion of two drams of each to a pint of water, is used as a repellent fermentation for some cutaneous eruptions, for cleansing foul ulcers, and as an injection in the fluor albus and gonorrhoea, when not accompanied with virulence. This vitriol is sometimes likewise employed as an errhine, and said to be a very effectual dissolvent of mucous matters; in which intention it is recommended, in the German Ephemerides, against obstructions of the nostrils in new-born infants.

2. Blue vitriol or vitriol of copper, commonly called Roman or Cyprian vitriol or blue-stone. This kind of vitriol is in many places produced from sulphureous ores of copper: the acid of sulphur is no other than the vitriolic; and the inflammable principle of the sulphur being dissipated either by fire or by a spontaneous resolution of the mineral, the acid remains combined with the copper: the vitriol, now formed, is either extracted by the application of water, or washed out by rain or subterraneous waters: hence in some copper mines are found blue waters, which are true vitriolic solutions of copper, and which deposit that metal on the addition of iron or of any other substance which the acid more strongly attracts. The greatest part of the blue vitriol, now met with in the shops, is prepared in England, by artificially combining copper with sulphur, or its acid.

The vitriol of copper is of an elegant sapphire blue colour, hard, compact, and semitransparent; when perfectly crystallized, of a flattish, rhomboidal, decahedral figure; in taste extremely nauseous, styptic, and acrid. Exposed to a gentle heat, it first turns white, and then of a yellowish red or orange colour: on increasing the fire it parts, difficultly, with its acid, and changes, at length, to a very dark red calx reducible, by fusion, with inflammable fluxes, into copper.

This salt, like the other preparations of copper, acts, in doses of a few grains, as a most virulent emetic. Its use is only external, as a detergent, escharotic, and for restraining hemorrhages: for which last intention, a strong styptic liquor is prepared in the shops, by dissolving three ounces of blue vitriol, and two of alum in a pint and a half of water, then adding two ounces of oil of vitriol, and filtering the mixture for use.

3. Green vitriol or vitriol of iron; commonly called English vitriol or copperas. This species of vitriol has iron wholly for its basis. It is formed solely of that metal, dissolved by the acid of sulphur, and by means of water, reduced to the form of salt. It is of two kinds, natural and factitious; the natural, or native kind, is known by the name of green vitriol, the common appellation of the other is copperas.

It is a tolerably pure and pellucid salt, of a compact and regular texture, considerably heavy, but friable, and easily shattering to pieces on the smallest blow. It is of a fine, pale, grass-green colour: it will not melt, or wholly run to water in a damp air, but it is very apt to be moist on the surface; it very readily dissolves in water, and after evaporation, freely shoots again into regular crystals, the true figure of which is a regular rhomboid;

rhomboid; but they are seldom perfect or regular. Exposed to the fire, it becomes thin like water, boiling and bubbling up, and emitting a very thick fume. After this it grows thicker, and, finally, calcines to a grey powder; and from this, if the fire be continued and made more violent, to a fine purple matter, called calcothar of vitriol.

A solution of this vitriol will curdle milk. It gives a greenish colour to syrup of violets. It makes no change in a solution of corrosive sublimate; with lime water, or a solution of tartar, it becomes of a dusky yellowish colour; and with a decoction of galls, which is the readiest of all tests for it, it becomes ink. It is to be chosen in large pieces, dry, clear, and transparent, of a fine green colour, and with none of that earthy matter among it, which is too frequent in the larger parcels of it.

The native green vitriol is found often in irregularly shaped masses, from an ounce or two, to a pound or more in weight, among the ore in the mines where there is iron. These masses are frequently covered over with irregular prominences, sometimes with regularly figured crystals of a rhomboidal form on their surfaces. It is also frequently found hanging down from the roofs, and along the sides of caverns, in form of icicles, perfectly resembling those of sparry matter, which our Derbyshire mines abound with, and which are commonly known by the name of stalactitæ. This is called stalactical vitriol. There are of these from the thickness of a straw to three or four inches in diameter, and from an inch to two feet in length. They are generally formed pretty regularly, tapering from the base to the opposite end; but they are not smooth or equal on the surface, but usually full of roundish protuberances; they appear transparent, if held up to the light, and when broken, shew an even and glossy surface.

Native vitriol, of both these forms, is frequent in the mines of Gosselaer in Saxony, in those of Bohemia, and in several of those of the Harts-forest, in Germany.

The factitious green vitriol which we usually call copperas, is, in all respects, the same with the native, except in its form, and manner of production.

The vitriol, in masses of fossil matter from which this is separated, is truly in the state of ore; it does not appear to the eye, but it is more or less discoverable by the taste.

The several kinds of vitriol ores, in this sense of the term, are very different from one another, and are very numerous. The most frequent, and one of the richest in vitriol, is the common pyrites of our clay-pits. This is a body which assumes various forms in its several masses, but is always of a dusky greenish colour; and where it has not been determined in its shape by some animal or vegetable mould, is usually flattish, and is seldom found in very large masses. It is extremely frequent in all our clay pits about London, in which places we meet with it, also, in a multitude of other various forms, it sometimes having been cast in shells of sea-fish, especially of the buccinum, nautilus, and concha anomia kind, and very frequently in the form of wood, whose pores it has entered, and lodged itself in the same manner as in the particles of stone in the ordinary petrified wood. Among the various pieces of wood it meets with in these strata, some of which appear to have been fragments of the bodies of trees, others of the smaller branches, it not unfrequently has lodged it among such masses as have before been eaten by sea-worms, and have formed the syringoides. These species, when petrified in the common way, make what is called the lapis syringoides; in this state they are called the pyrites syringoides; in all these, and the thousand other shapes in which this pyrite offers itself to our view, it is itself the same substance in every respect. It is hard, compact, and firm, as it lies in the earth, though it soon grows friable and shattery on being exposed to the air. It is covered with no coat or crust, but shews its own natural surface; and when broken, it appears of a simple uniform structure, and of the same colour within as at the surface. If struck against a piece of steel, it gives fire freely, and the sparks are large and very bright. It

will not ferment with any acid, and when tried by fire, it cracks and bursts, and burns with a fine blue flame, and a strong smell of sulphur, finally, calcining to a fine, deep, red colour.

Besides this species of the pyrites, which is the most frequent, the richest in vitriol, and the most usually worked for it, all the other pyritæ, and all the marcasites, without one exception, contain it. There are several stony substances, also, very highly impregnated with it, of which, in Germany particularly, they meet with some that are of a reddish hue, as if they had been naturally calcined in the earth; others of a fine, bright, golden yellow, from the quantity of the yellow mundic contained in them; others of a dusky grey, and others of a deep black. The ores of metals, also, frequently contain large quantities of the ore of this vitriol among them, and even the last mentioned kinds of genuine ores of the vitriol, not unfrequently, contain, also, particles of the metals among them. The mundic, or common marcasite of Cornwall, is of this number, containing, frequently, metalline matter in it, and always vitriol and sulphur.

The pyritæ that afford this vitriol, always contain iron and sulphur in them, and copper very frequently, and sometimes arsenic: when they contain only iron, they generally crack and shoot out their salt very quickly and easily on being exposed to the air; those which contain copper, especially if there is arsenic among the mass, do not break so soon, but often will stand the effects of the air ever so long, and require to be calcined and wetted before they will shoot, or give any token of the salt they contain, though they have it in great abundance.

A multitude of other substances contain the green vitriol, which one would hardly suspect of it; among these we may mention the brown iron ore of the Gosselaer mines, the reddish ferrugineous stones found over the strata of coal in Mendip-hills, and in some other parts of England, and the common calamine. All calamine contains some of this green vitriol; but from the naturally red pieces, it separates in a very large proportion; and in the cavernous hollows of some of its masses sent from the German mines, small masses of the native white vitriol have also been seen, which is the less wonderful, indeed, as zinc, which is the metalline matter contained in calamine, is the very substance which gives the vitriol of iron its white colour.

The calamines are all of the number of those ores which will not shoot on being merely exposed to the air; they must be previously roasted and sprinkled, at times, with water.

The ores of alum, also, frequently contain vitriol, and the alum is less easily separable from these, than from such as contain only that salt. Hence arises the account we meet with, among people less informed of these things, of stones and earths very strongly tasting of alum, but from which no alum can be obtained. The business is, that in working them for their salt, the vitriol shoots first, as the common salt mixed with nitre does, in the purifying that salt; but if these people, after the vitriol is shot, would throw some alkali into the remaining liquor, they would soon find their alum. The common Irish slate, and many other of the fossil alum ores, contain vitriol in abundance.

The Germans make green vitriol from any of the ores we have been mentioning, by burning, and afterwards exposing them to the air; and in some places they first of all melt the sulphur from them, and then work them for their vitriols.

In England, where the greatest quantity of this vitriol is made, it is formed from the common greenish pyrites, with the addition of old iron. The people who collect these pyrites, are not at the pains of searching it among the strata, but they pick it up on the sea coasts of Essex, and other places, under cliffs, composed of strata of clay, out of which the sea washes it, and leaves it on the shore. This pyrites they expose to the air in vast heaps, and, in consequence of that, it by degrees begins to swell and burst, and shoot out in salts. They pile up these heaps in a kind of pits lined with clay,

clay, now and then turning them when their salt begins to appear in a downy efflorescence on the surfaces of the pieces they fall into, on breaking; the time of making vitriol being near.

These efflorescences dissolve by the rains and dews, and are, in fine, converted into an acrid liquor, which is conveyed from the bottom of the pits into leaden boilers, into which a quantity of old iron is also thrown; the fire is made under these, and the liquor is kept boiling for three days, or more, and is all the time supplied with fresh parcels of iron, so long as it will act upon them. The old iron, picked up by the poor people about our streets, is sold to the vitriol or copperas makers with this intent. When the liquor is boiled to a proper consistence, it is let out into large coolers, in which there are sticks placed across, to which, as well as to the sides of the vessel, the vitriol adheres in large crystals, of the form and texture above described.

Pure vitriol of iron is considerably transparent; of a fine bright, though not very deep, grass green colour; of a nauseous astringent taste, accompanied with a kind of sweetishness. Dissolved, and set to crystallize, it shoots into thick rhomboidal masses; a part generally rising at the same time in efflorescences about the sides of the vessel. The solution deposits in standing a considerable quantity, and in boiling a much larger one, of the metallic basis of the vitriol, in form of a rusty calx or ochre: iron seems to be the only body that thus separates spontaneously, in any considerable quantity, from the vitriolic acid. On exposing the vitriol itself to a moist air, a similar resolution happens on its surface; which, sooner or later, according as the acid is more or less saturated with the metal, changes its green to a rusty hue. In a warm dry air, it loses a part of the phlegm or water necessary to its crystalline form, and falls by degrees into a white powder. Exposed to a gentle fire, it liquefies and boils up; but soon changes, on the exhalation of the watery part that rendered it fluid, to a solid, opaque, whitish or grey mass: this, pulverised and urged with a stronger fire, continues to emit fumes, becomes yellow, afterwards red, and, at length, having parted with most of its acid as well as its phlegm, turns to a deep purplish-red calx, revivable by inflammable substances into iron.

Pure green vitriol is in no respect different from the artificial *sal martis*. It is one of the most certain of the chalybeate medicines, scarcely ever failing to take effect where the calces and other indissoluble preparations pass inactive through the intestinal tube. It may be conveniently given in a liquid form, largely diluted with aqueous fluids: two or three grains or more, dissolved in a pint or a quart of water, which from this quantity receives no disagreeable taste, may be taken in a day, divided into different doses. This vitriol is used also, especially when calcined, as an external styptic: the styptic of Helvetius, and as is said that of Eaton, is no other than French brandy very slightly impregnated with the calcined vitriol: a dram of the vitriol is commonly directed to a quart of the spirit, but only a minute portion of the dram dissolves in it. As French brandy has generally an astringent impregnation from the oaken casks in which it has been kept, the vitriol changes it, as it does the watery infusions of vegetable astringents, to a black colour: but makes no such change in spirituous liquors that have not received some astringent tincture.

It is from the green vitriol that the acid called vitriolic has been generally extracted; by distilling the calcined vitriol in earthen long necks, with a strong fire continued for two days or longer. The distilled spirit appears of a dark blackish colour; and contains a quantity of phlegm, greater or less, according as the vitriol has been less or more calcined. On committing it a second time to distillation, in a glass retort placed in a sand-heat, the phlegmatic parts rise first, together with a portion of the acid, and are kept apart under the name of spirit or weak spirit of vitriol: at the same time the remaining strong spirit, or oil as it is called, loses its black colour and becomes clear, and this is the usual mark for discontinuing the rectification.

The strong acid or oil of vitriol is the most ponderous of unmetallic fluids, and the most fixed of saline ones; yielding no smell in the greatest heat of the atmosphere, and requiring, to make it boil or distil, a heat considerably greater than that in which lead melts. Exposed to the air, it imbibes its humidity, so as to gain by degrees an increase of about twice its own weight. Mixed directly with water, it produces a heat so great as to render the vessel insupportable to the hand: glass vessels are apt to crack from the suddenness of the heat, unless the commixture is very slowly performed. The most ready method of distinguishing it, in a dilute state, or when mixed with other acids, is by adding a solution of some calcareous earth, as chalk, made in any kind of acid liquor: this solution is by a minute portion of the vitriolic acid rendered milky, but suffers no change from any other species of acid.

If the long-neck, in the extrication of the acid from vitriol, happens to crack in the fire, the acid that rises after this period is found remarkably changed. It emits in the air suffocating vapours like the fumes of burning brimstone, and rises in distillation with a heat not much greater than that which the hand can bear: to the taste it discovers little corrosiveness or acidity. Combined with alkaline salts, it loses its pungent odour; but on the addition of any other acid, it is disengaged from the alkali, so as to rise again in distillation as volatile and suffocating as before. It destroys or whitens the blue and red colours of the flowers of plants; whereas, in its fixt state, like the other acids, it changes the blue to red, and heightens those which are naturally red. This volatile spirit loses its suffocating odour, and resumes its corrosiveness, fixedness, and other qualities, by exposure to the air, which seems to carry off the inflammable principle whereon its volatility depended.

The fumes of burning brimstone are no other than the vitriolic acid in its volatile state. If a little burning sulphur be suspended over some water in a close vessel till the fumes subside, and this repeated with such portions of sulphur till about half a pound has been used to a quart of water, the liquor will be found strongly impregnated with the volatile suffocating acid; and in keeping for some time, if the vessel is not closely stoppt, it will become exactly similar to water acidulated with the fixt acid. If a very large glass, open at bottom, be hung over the burning sulphur, in a damp place screened from wind, a part of the fumes will condense upon the sides of the glass, and run down in drops, which may be collected by placing a glass dish underneath: the acid thus obtained is called, from the shape of the vessel that has been generally used for condensing the fumes, spirit or oil of sulphur by the bell. The quantity of acid collected by this process is very small, greatest part of the fumes escaping: sixteen ounces of sulphur, in the most favourable circumstances, yield scarcely one ounce of phlegmatic spirit; though it is certain, that out of this quantity of sulphur, more than fifteen ounces are pure acid, of such strength as to require being diluted with above an equal quantity of water to reduce it to the pitch of common spirit of sulphur; so that if sulphur could be burnt without the loss of any of its fumes, we might obtain double its weight of an acid of the ordinary strength. The process has lately been improved, by some particular persons, though not perhaps to this degree, yet so far as to afford at a very low price almost all the acid now sold under the name of oil of vitriol. The improvement consists in burning the sulphur in very large glass vessels, in the bottoms of which some warm water is placed, whose steam serves to collect and condense the fumes; and in mixing with the sulphur a small portion of nitre, which enables it to burn without communication with the atmosphere.

The acid of vitriol or sulphur, largely diluted so as to be supportable, or be gratefully tart to the palate, is the most salubrious of all the mineral acids. It is mixed with watery infusions, spirituous tinctures, and other liquids, as an antiphlogistic; as a restraining in hemorrhages; and as a stomachic and corroborant in weaknesses, loss of appetite, and decays of constitution, accompanied with slow febrile symptoms, brought on by irregularities,

ties, or succeeding the suppression of intermittents by Peruvian bark. In several cases of this kind, after bitters and aromatics of themselves had availed nothing, a mixture of them with the vitriolic acid has happily taken place: the form commonly made use of is that of a spirituous tincture: six ounces of oil of vitriol are dropt by degrees into a quart of rectified spirit of wine, the mixture digested for three days in a very gentle heat, and afterwards digested for three days longer with an ounce and a half of cinnamon, an ounce of ginger, and half an ounce of the dry leaves of pepper-mint; or a pint of an aromatic tincture drawn with proof spirit is mixed with four ounces of the strong acid: these liquors are given from ten to thirty or forty drops, in any convenient vehicle, at such times as the stomach is most empty. A mixture of oil of vitriol with spirit of wine alone, in the proportion of one part of the former to three of the latter, digested together for some time, is used in France as a restraining in gonorrhœas, female fluors, and spittings of blood.

When oil of vitriol and rectified spirit of wine are long digested together or distilled, a part of the acid unites with the vinous spirit into a new compound, very volatile and inflammable, of no perceptible acidity, of a strong and very fragrant smell, and an aromatic kind of taste: this dulcified part, more volatile than the rest, separates and rises first in distillation, and may thus be collected by itself. The college of London directs a pound of oil of vitriol and a pint of rectified spirit of wine to be cautiously and gradually mixed, a great conflict and heat ensuing if they are mixed hastily, and set to distil with a very gentle heat: that of Edinburgh orders the same quantity of the oil of vitriol to be dropt into four times as much of the vinous spirit, and the mixture to be digested in a close vessel, for eight days, previously to the distillation, with a view to promote the coalition of the two ingredients. The different proportions of the acid spirit to the vinous, in these prescriptions, make no material variation in the qualities of the product, provided the distillation is duly conducted; for the smallest of the above proportions of acid is much more than the vinous spirit can dulcify, and all the redundant acid remains in either case behind. The true dulcified spirit rises in their subtle vapours, which condense upon the sides of the recipient in straight striæ: these are succeeded by white fumes, which form either irregular striæ, or large round drops like oil; on the first appearance of which, the process is either to be stopt, or the receiver changed. The spirit which these fumes afford, very different from the dulcified one, has a pungent acid smell like the fumes of burning sulphur: on its surface is found a small quantity of oil, of a strong penetrating and very agreeable smell, readily dissoluble in spirit of wine, to a large proportion of which it communicates the smell and taste of the aromatic or dulcified spirit. The college of Edinburgh, in order to secure against any acidity in the dulcified spirit, order it to be rectified, by mixing it with an equal measure of water, in every pint of which a dram of salt of tartar has been dissolved, and drawing off the spirit again by a gentle heat.

This spirit, taken from ten to eighty or ninety drops, strengthens the stomach and digestive powers, relieves flatulencies, promotes urine, and in many cases abates spasmodic strictures and procures rest. It is not essentially different from the celebrated mineral anodyne liquor of Hoffman; to which it is frequently, by the author himself, directed as an alternative. It is evident, from Hoffman's writings, that his anodyne was composed of the dulcified spirit and the aromatic oil which comes over after it, but the particular proportions of the two he has no where specified: the faculty of Paris directs, under the title of his preparation, twelve drops of the oil to be dissolved in two ounces of the spirit; the college of Wirtemberg seems to think, that all the oil and all the spirit, obtained in one operation, were mixed together, without regard to the precise quantities.

The dulcified spirit is sometimes used as a menstruum for certain resinous and bituminous bodies, which are more difficultly and languidly acted upon by pure vinous spirits. It is often mixed with aromatic and stomachic

tinctures, in cases where the stomach is too weak to bear the acid elixirs abovementioned: eight ounces are commonly added to a pint of the officinal aromatic tincture, in which it does not, like the acid undulcified, occasion any precipitation. A medicine of this kind was formerly in great esteem under the name of Vigan's volatile elixir of vitriol, the preparation of which was long kept a secret, and first made public in the *Pharmacopœia Reformata*: it is prepared by macerating, in some dulcified spirit of vitriol free from acidity, a small quantity of mint leaves curiously dried, till the spirit has acquired a fine green colour: to prevent the necessity of filtration, during which the more volatile parts would exhale, the mint may be suspended in the spirit in a fine linen cloth.

If the dulcified spirit, rectified as above prescribed from a solution of fixt alkaline salt, be shaken with equal its quantity of a like solution, and the mixture suffered to rest; an ethereal fluid rises to the surface, and great part of the dulcified spirit may be recovered again from the remainder by distillation. We are informed by Dr. Hadley, that he has observed the largest proportion of ether to be obtained, by using the strongest vitriolic acid of the shops with twice its quantity of spirit of wine, and distilling immediately by a heat sufficient to make the mixture boil; and that by this management, from three pounds of oil of vitriol and six pints of rectified spirit of wine, he obtained two pints and a half of the ether.

The ether or ethereal spirits is the lightest, most subtle, volatile, and inflammable, of all known liquids: it quickly exhales in the air, diffusing an odour of great fragrance: it does not mingle with water, with acid liquors, with alkaline liquors, or with vinous spirits, but dissolves oils, balsams, and resins, and extracts the oily and resinous parts of vegetables. It has been hitherto regarded chiefly as a matter of curiosity, nor are its medicinal qualities as yet much known. Malouin looks upon it as one of the most perfect tonics, friendly to the nerves, cordial and anodyne; and says he has found it to be a good remedy in rheums, for abating coughs, especially those of the convulsive kind. Its great volatility renders the taking of it very inconvenient: the author abovementioned orders, as the most convenient form, from three to twelve drops to be dropt on sugar or powdered liquorice, a little warm water or some warm infusion to be immediately added, and the whole swallowed directly. It has been reported to give immediate ease in violent head-achs, by being rubbed on the temples.

The vitriolic acid saturates a larger quantity of fixt alkaline salts than any of the other acids, and dislodges therefrom such other acids as have been previously combined with them: of the strong spirit or oil of vitriol, about five parts are sufficient for eight of the common vegetable fixt alkalies. The neutral salt, resulting from its coalition with this kind of alkali, is of a bitterish taste, very difficultly soluble in water, and scarcely fusible in the fire: in small doses, as a scruple or half a dram, it is an useful aperient; in larger ones, as four or five drams, a mild cathartic, which does not pass off so hastily as the sal catharticus, and seems to perform its office more thoroughly. This salt has been commonly prepared with the alkali obtained from tartar, and is hence called vitriolated tartar: some dilute the oil of vitriol with an equal quantity of warm water, and drop into it a solution of the alkaline salt till a fresh addition occasions no further effervescence: others, instead of the pure acid, use vitriol in substance, which being dissolved in boiling water, any alkaline salt, gradually superadded till the effervescence ceases, absorbs the pure acid, and throws down the metallic basis of the vitriol; one part of the alkali is nearly sufficient for two of the vitriol: this last method, more troublesome than the other in regard to the preparation, more effectually secures the medicine from a redundancy of acidity. The wholesale dealers substitute for this salt that which remains after the extraction of the acid of nitre by means of oil of vitriol, which when duly prepared, is exactly the same: but as they commonly employ in that process an over-proportion of the vitriolic acid, and vend the remaining salt uncrystallized, we often meet with it so very acid as to be utterly unfit for use.

With

With the mineral fixt alkali, and the earth called magnesia, this acid forms compound salts of a bitterer taste, somewhat less purgative, and much easier of solution, than that with vegetable alcalies: with volatile alcalies a very pungent ammoniacal salt, whose medicinal effects are not well known. The strong acid, boiled on argillaceous earths to dryness, corrodes a portion of them, and concretes therewith into an austere styptic salt. Calcareous earths it does not dissolve into a liquid state, but may be combined with them, by precipitation from other acids, into an indissoluble concrete seemingly of no medicinal activity. Among metallic bodies, it dissolves zinc and iron readily; copper, silver, quicksilver, lead, and tin, very difficultly: it is fitted for acting on the two first by dilution with three or four times its quantity of water: the others require the undiluted acid, and a heat sufficient to make it boil; when, the more phlegmatic parts exhaling, so much of the pure acid matter remains combined with the metals, as to render them, in part at least, dissoluble in water.

The medical qualities of the acid in its volatile state are very little known, and those of the combinations thereof with alcalies not at all, though they should seem to deserve enquiry. The volatile acid of burning brimstone may be commodiously transferred into fixt alcalies, by dipping linen clothes in a strong solution of the alkali, and suspending them over the fumes, of which they will quickly imbibe so much as to neutralize the alkali: this neutral salt being rubbed off, the clothes may be again moistened with the alkaline ley, exposed to the acid fumes, and these processes alternately repeated. The neutral salt thus obtained differs greatly in its taste and other properties, and doubtless also in its medical virtues from that which is produced by the coalition of the fixt acid with the same alkali, that is from vitriolated tartar. It dissolves more easily in water, and shoots, not into octangular crystals, but into small slender ones like short needles. On adding to it the fixt vitriolic acid, or even the weaker acids of nitre or sea-salt, the volatile acid is disengaged from the alkali, and though, in the compound salt, its pungent smell was wholly suppressed, it now rises in distillation as pungent and suffocating as the original fumes of the brimstone. The neutral salt, in a dry form, may be kept unchanged for years: dissolved in water and exposed for some time to the air, or if roasted with a gentle heat, it becomes the same with vitriolated tartar.

VITRIOL of Copper. The glass-makers have a method of making this without corrosives, which was originally practised by Neri, and with which they make very fine colours in glass, particularly a fine sea-green.

The method of making the preparation is this: take little thin pieces of brass, and lay them stratum super stratum in a crucible, with powder of brimstone. When the vessel is full, set it luted and covered in an open wind furnace, with burning coals over it, and let it stand two hours, then let the furnace cool of itself, and take out the crucible; the mass within will be of a blackish obscure purple; powder and sift it fine, and then, mixing with every pound of it six ounces of powdered brimstone, take a round vessel of earth that will bear the fire, place it upon iron bars set across in an open wind furnace, fill it with coals, and then put in the powder; keep it burning and stirring about till all the brimstone is burnt up; then take out the pan, and powder the calcined mass again, sift it fine, and proceed with it thrice as before; the last time let it stand on the fire till it become red. Put a pound of this calcined copper into a glass body, with six pints of water; evaporate two pints or thereabouts in a sand heat; the water is then of a fine blue, and must be poured off clear; then filtrate it. Evaporate the water from the remaining sediment of copper left in the glass, and with new sulphur calcine it again and again; repeat this five or six times, and extract the blue tincture with water as before; filtrate all the waters, and put them together. Evaporate all to a fifth part or thereabouts, and set it in a cool place, and fine pointed crystals will be formed, resembling emeralds; separate these crystals, and evaporate the water again, till all the crystals be procured.

Then put a pound of them into a glass retort, well luted and fitted to a capacious receiver; let the joints be well closed, and make a moderate fire for four hours; then make it violent for twenty hours, or till no more white fumes arise. The next day open the receiver, and separate the liquor into a glass, where it must be kept carefully sealed up. *Neri's Art of Glass.*

VITRIOLATED, among chemists, something that has vitriol infused in it.

VITRIOLIC, an appellation given to whatever abounds with, or partakes of, the nature of vitriol: thus such fossile bodies as contain vitriol, are called vitriolic minerals, or ores of vitriol; as the pyrites, chalcitis, misy, sory, melanteria, marcasites, &c.

VITRIOUS, or **VITREOUS Humour of the Eye.** See **VITREOUS**.

VITTA, in anatomy, that part of the amnios, which sticks to an infant's head, when just born.

VITUS's DANCE, *Chorea Sancti Viti*, in medicine, a sort of convulsion, which boys and girls are subject to; from the age of ten years, to the time of puberty: it discovers itself first by a kind of lameness, or an instability of one of the legs, which they draw after them in a ridiculous manner; nor can they hold the arm of the same side still for a moment; and before they can bring a cup to their mouth, they use a thousand odd gesticulations. In a convulsive paroxysm, the limbs are strongly agitated; the hands are sometimes put behind them, and soon after they seem to be beating the air; and their legs will be drawn hither and thither, as if they were dancing some antic dance. See **CONVULSION** and **SPASM**.

Dr. Mead thinks this disorder to be rather paralytic than convulsive, and that it may be cured by use of cold baths, and chalybeate medicines. Sydenham's method of cure is this: first take off seven or eight ounces of blood, more or less according to the strength of the patient, from the arm; and the next day, let the patient take a gentle purge of rhubarb, senna, manna, &c. In the evening of the same day, let him take a draught, with a scruple of Venice-treacle, and eight drops of liquid laudanum mixed in honey and milk-water. This purging and opiate draught is to be repeated at some days distance; the bleeding is also to be repeated to the fourth time; and in the intermediate days, a cordial and nervous electuary is to be given, composed of the conserves of rosemary, orange-peel, and Roman-wormwood, with Venice-treacle, candied nutmeg, and candied ginger; of this, the bigness of a nutmeg may be given every morning and afternoon, drinking after it a decoction of piony, master-wort, and elecampane, and angelica-roots, the leaves of rue, sage, betony, and other cephalic plants, with orange peel and juniper-berries. Spirit of hartshorn may also be given every night in small doses, in a nervous julep, and plasters of gum-caranna may be applied to the soles of the feet. According as the cure advances, the patient recovers the use of his hand and foot; and his amendment may always be discovered by letting him attempt to bring a glass of any liquor to his mouth in a strait line: though the bleeding should not be repeated beyond the fourth time, yet the alterative and purging medicines should be continued till the patient is quite well; and as people are subject to relapses in this disorder, it is proper to give the same medicines, and to bleed at the return of that season of the year.

VIVA VOCE, a Latin phrase frequently used in English writers, and literally signifying by word of mouth.

VIVIFICATION, in medicine, the art of vivifying; that is, of contributing to the action that gives life, or maintains life.

The chemists, also, use the word in speaking of the new force, vigour, and lustre, which, by this art, they give to natural bodies; particularly to mercury, which, after having been fixed or amalgamated, they restore to its first state.

VIVIPAROUS, *viviparus*, in natural history, an epithet applied to such animals as bring forth their young alive and perfect, in contradistinction to them that lay eggs, which are called oviparous animals.

The

The females of all the quadruped class are viviparous, and those of the bird class are all oviparous. The laws of nature in the larger animals, are therefore, in a great measure, fixed and certain, but it is not so in the insect tribes, nor in the fishes; for of these some are viviparous, and others oviparous; and those of genera nearly allied to one another. Among insects, the much greater number are oviparous; but there are many which are not so, as the pucerons, progallinsects, cochineal, &c. The millepedes and scorpions are also well known to be so; all the females of the butterfly, and of some other classes, lay only eggs; but the most singular and remarkable inconstancy in nature, if we may be allowed the expression, is that in the fly kingdom; the same class of insects, and even the same genus, will furnish us with some which are viviparous, and others which are oviparous; the two-winged flies give us instances of this: but these are not single in that respect; for among the reptile world, there are other creatures which are subject to the same varieties; and Swammerdam has observed a viviparous snail. The two winged viviparous flies bring forth worms in all respects the same with those hatched from their eggs in the other species.

VIVO, in architecture, the shaft or fust of a column.

The term is also used in a more particular sense for the naked of a column, or other part.

ULCER, *Ulcus*, in surgery, is a solution of the soft parts of our bodies, together with the skin, produced by some internal cause, as an inflammation, abscess, or acrimonious humours. But wounds which become inveterate, and even contusions, when difficult of cure, come within this definition, and pass, at length, into ulcers, and are commonly so called.

The proper and usual seat of an ulcer, then, is in any of the softer parts of the body, as the skin, fat, glands, flesh, and internal viscera. For if there be any exulceration or corrosion in the harder parts, as the bones, it comes rather under the notion of a caries, or what is commonly called spina ventosa, than that of an ulcer; though, on account of some kind of resemblance which it has with the ulcer, or erosion, of the softer parts, they are sometimes treated of in conjunction.

Ulcers can by no means be reckoned all of one kind, but are distinguished into various species, on many accounts; as, 1. With respect to the different parts of the body in which they are seated; for, sometimes they infect the skin, at other times the fat, and sometimes the glands and flesh.

2. As to their magnitude; for some ulcers are large and extended, others small, and contracted within narrow limits; some deep, others shallow, and more superficial: in particular, ulcers of a considerable depth, but narrower, and more especially distinguished by the narrowness of their orifice or beginning, usually pass under the peculiar denomination sinus or fistula. Ulcers differ,

3. With regard to duration; for some are recent, others inveterate.

4. On account of their attendant symptoms; in which respect some ulcers are mild and favourable, others malignant, that is, attended with very acute pains, or fetid, putrid, pinguious, rheumy, or discharging much ichor, creeping or spreading, cancerous, or inclining to a cancer, callous, fistulous, or verminous; there is a difference between them.

5. With respect to their causes, in which light they assume the epithets of scorbutic, venereal, carious, cancerous, pestilential, and such as are supposed to proceed from fascination. In the last place, ulcers are distinguished by the parts in which they are seated. Thus, some infect the nostrils, others the fauces, palate, breasts, and anus; and one sort has the name of fistula lacrymalis.

The method of cure in ulcers is extremely various, as adapted to the great variety of the disease; for when the ulcer is but recent, it is to be healed in the same manner as a recent wound or abscess. We must first, then, begin with mundification, or cleansing the ulcer; after that proceed to incarnate, or fill the cavity with new flesh; and, lastly, cover and conglutinate the same as much as possible, with a fair and even cicatrix.

Mundification of an ulcer is, according to Heister, usually performed in the following manner: first, the corrupted matter is evacuated; or, when it discharges itself not so freely as it ought, gently expressed with the fingers; if there be a deep sinus belonging to the ulcer, it is to be extirped by some proper injections; or, if the place be open enough, by repeating intromissions of fresh lint. If there be any pieces of membranes, or other corrupted pinguious parts, left in the ulcer, the best way to eject them is, at every dressing, to introduce into the place lint moistened with some digestive ointment, and cover it with a plaster of diachylon, diapalma, or something of the like nature; and upon that, apply compresses, and over the whole a bandage: this method is to be carefully followed till the place be thoroughly cleansed, or till the bottom of the ulcer appears quite red, and covered with new flesh.

After due mundification, the next business is to fill the ulcer with new flesh, which is performed by the help of such medicines as are commonly called sarcotics.

The best and most effectual, by many degrees, is the digestive ointment; for without some extraordinary impediment, this digestive is, of itself, sufficient to produce new flesh. It is, indeed, the manner of almost all surgeons very gravely to recommend every one his proper balsamics for the procuring of new flesh; but it is presumed, there is no necessity for them to be so careful and solicitous in this point, since there is, in this very digestive, a balsamic virtue; and it ought, besides, to be considered, that this new flesh owes its generation, not so much to the assistance of medicines, as the benefit of nature: for all the care and diligence of the surgeon have scarce any other effect, than to remove all such things as are hurtful, and may prove impediments to a cure. If any one, however, should think this digestive ointment not strong enough for his purpose, he may try balsam of Arcæus, balsam of Peru, balsam of Mecca, balsam of sulphur, essence of myrrh and aloes, oil of myrrh per deliquium, oil of eggs, and other vulnerary balsams of the like kind, which may be used in its stead; and, by the best means he can procure, to accomplish a perfect conglutination.

When an ulcer has penetrated so deep as to have its bottom remote, not only from sight, but from the reach of medicines, it may seem necessary in every dressing, after expressing the corrupted matter collected within, to make an injection of some cleansing and healing liquor; such as a decoction of agrimony and birthwort mixed with honey of roses, or essence of myrrh and aloes, or what Belloste, in his Hospital Surgeon, recommends, a decoction of walnut leaves mixed with sugar before the place be bound up, till the bottom is conglutinated, and to continue the same till the ulcer is filled up.

The ulcer being, by some means or other, as may seem most adviseable, incarnated and filled up, the induction of a fit and decent cicatrix must be completed; but if by such means you cannot prevent a luxuriancy of flesh, with a moistness of the ulcer, it will be proper to sprinkle on the part some drying powders, such as those of mastic, frankincense, sarcocolla, colophony, lapis calaminaris, and tutty; applying, afterwards, to the place dry lint, and a plaster accommodated to retain and hold together all the things applied, continuing the same till the place be perfectly whole and sound: but if the luxuriant and fungous flesh has already elevated itself above the rest, above the skin, the best way to consume it, is to rub it with blue vitriol; or, if this be not strong enough, to sprinkle on it some powder of red precipitate and burnt alum, till its growth be entirely suppressed, and nothing appears prominent.

In the last place, it is hardly to be expressed how much a prudent regimen in diet and manner of living contributes towards the incarnating and conglutination of ulcers: for it has been an old observation of the professors of the salutary art, that very bad ulcers have been cured by means of a regimen, without any considerable assistance from medicine; and, on the contrary, that the slightest and most contemptible sores have, by a neglect of the rules of diet, and preposterous way of living, degenerated into very bad, and even incurable, ulcers.

Great care, therefore, is to be taken by every person troubled with an ulcer, to avoid salt, acrid and acid food, and such as is too fat or heating, with swine's flesh, and all such as is difficult of concoction. If a bad habit of body be an impediment to the cure of an ulcer, the advice of a skilful physician is required, who, by the prescription of proper internal medicines, may not only prevent an ulcer of a mild and favourable kind from becoming malignant, and perhaps incurable, but as much as possible promote and hasten its cure.

In callous and fistulous ulcers, that have formed variety of sinuses, and when either nothing can be done by corrosive medicines, or else that they tear and corrode the nerves, and bring on convulsions, and other bad symptoms, before they affect the callus; in these cases, the best and safest way is to lay open the sinus, taking care not to wound the nerves, tendons, and arteries; and, after that, all the calluses may be easily destroyed by the common methods. Or, if even this method should not have the desired effect, and if the patient has a considerable share both of strength and courage, and the situation of the nerves and arteries is favourable, the callous parts must be all either entirely cut out with the knife, or burned away by the actual cautery.

When ulcers are attended with a large discharge, the acrimonious serum, wherewith the blood abounds, should be evacuated by cathartic and diuretic medicines. Mil-lepedes, in any form, are very properly prescribed to be taken internally in these, as are also the essence of amber, myrrh, balsam of Peru, tincture of salt of tartar, tartarized tincture of antimony, and the like: large and frequent draughts of small liquors are frequently the cause of these disorders, and are therefore most carefully to be avoided; strong ale, or old wine, should be drank sparingly at meals, and nothing between them. Such meats are best, on these occasions, as have fewest juices in them, and are very well roasted; and the external medicines must be those which have the greatest reputation as dryers. The principal of these are lime-water, lapis calaminaris, tutty, chalk, mastix, frankincense, colophony, and native cinnabar; and when any of these have been sprinkled in fine powder upon the ulcer, a plaster of diapompholygos, or the like, is to be laid over it.

For the cleansing venereal ulcers, Heister recommends the phagedenic water; or lime-water, impregnated with calomel: either of these may be applied often every day, and the parts may also, if necessary, be touched with the caustic; and when they are thoroughly cleansed, they may very successfully be healed, either with an ointment made only of crude mercury mixed with turpentine, or with the following: take of the diapompholygos-ointment and crude mercury, killed with a small quantity of Venice turpentine, of each equal quantities; mix them in a glass mortar into an ointment: or, take of the amalgama of lead and tin an ounce, of bole armenic two ounces; mix these, and make them into an ointment by mixing with them a sufficient quantity of ointment of roses, or any other simple ointment, in a glass-mortar. If there be at the same time a caries of the bone, which is, indeed, too frequently the case, this is to be dressed with euphorbium, oil of cloves, phagedenic-water, or spirit of nitre with quicksilver dissolved in it; or, if it can conveniently and safely be done, the actual cautery is of signal service.

ULCERATION, or EXULCERATION, in surgery, a little hole in the skin, caused by an ulcer.

ULIGINOUS, in agriculture, an appellation given to a moist, moorish, and fenny soil.

ULLAGE, in gauging, is so much of a cask, or other vessel, as it wants of being full. See GAUGING.

ULMUS, the elm, in botany. See ELM.

ULNA, in anatomy, one of the bones of the forearm, reaching from the elbow to the wrist: it is big at its upper extremity, and grows gradually smaller towards its lower end.

This bone is longer than the radius, and has a motion of flexion and extension: at its upper extremity, it articulates with the os humeri and the crista of the radius; and its lower extremity articulates with the carpus, as also with the radius by means of a crisis.

ULNA, an ell. See the articles ELL and MEASURE.

ULNARIS, in anatomy, the name of two muscles of the carpus, or hand; one called ulnaris internus, which is a flexor muscle terminating in the internal ossicle of the carpus; and the other, called ulnaris externus, is an extensor muscle, terminating in the metacarpal bone that supports the little finger.

ULTERIOR, in geography, is applied to some part of a country or province, which, with regard to the rest of that country, is situated on the farther side of the river, mountain, or other boundary, which divides the country into two parts. Thus Africa, with regard to Europe, is divided, by mount Atlas, into Citerior and Ulterior, i. e. into two portions, the one on this side mount Atlas, and the other on that.

ULTRAMARINE, *Ultramarinum*, a beautiful blue colour used by the painters, prepared from lapis lazuli, by calcination. See LAZULI.

The German lapis lazuli does not answer well in this process, and discovers itself by its calcining easier than the African or Asiatic, and turning greenish. The oriental kind calcines to a finer blue than it naturally has, and retains the colour for ever.

After calcining the stone in a clear fire of charcoal, they grind it to an impalpable powder on a porphyry, and then mixing it up in a paste, composed of pitch, wax, and oil, they work it about with the hands; and, finally, kneading this in a vessel of clear water, as the powder separates from the viscid matter, it sinks to the bottom: when all that is perfectly fine in this, is worked out, they let the water be drained off, and dry the powder for use. What remains embodied in the paste, is afterwards separated, and makes a worse kind than the former; though even the very meanest ultramarine is a very beautiful colour.

Ultramarine must be chosen of a high colour, and well ground, which may be known by putting it between the teeth, and if it feel gritty, it is a sign it has not been well ground.

To know whether it be pure and unmixed, put a little of it into a crucible, and heat it red-hot; and if the powder has not changed its colour after this trial, it is certainly pure; on the contrary, if there be any change, or any black specks in it, then it has been adulterated.

There is also a spurious sort, called common or Dutch ultramarine; which is only smalt well ground and pulverized. See SMALT.

ULTRAMONTANE, something beyond the mountains. The term is principally used in relation to Italy and France, which are separated by the mountains of the Alps.

ULTRAMUNDANE, *Ultramundanus*, beyond the world; is that part of the universe supposed to be without, or beyond, the limits of our world, or system.

ULVA, in botany, a genus of water-plants, belonging to the cryptogamia class; the fructifications of which are disposed in membranous bladders, without the leaf.

UMBEL, *Umbella*, among botanists, is the extremity of a stalk or branch divided into several peduncles, or rays, beginning from the same point, and opening in such a manner as to form an inverted cone: these are either simple or compound; a simple umbel, is when the receptacle is but once divided into foot-stalks; but, a compound umbel, is when all the common footstalks are subdivided into umbellulæ, or little umbels. They are of different figures; as plane, convex, concave, or radiated.

UMBELLIFEROUS PLANTS, are those whose flowers are produced in an umbel, on the top of the stalks, somewhat representing an umbrella.

All the plants of this kind belong to the pentandria class of Linnæus; the flower is pentapetalous, and succeeded by two naked seeds, joined together. Those which grow wild in dry soils, are aromatic, warm, resolvent, and carminative; but those which grow in moist places are often poisonous: the virtue is chiefly in the roots and seeds; such are fennel, parsley, parsnips, carrots, hemlock, &c.

UMBER, or **UMBRE**, *Umbria*, among painters, &c. a kind of dry dusky-coloured earth, which diluted with water, serves to make a dark brown colour, usually called with us, a hair colour.

It is called umber, from *umbra*, a shadow, as serving chiefly for the shading of objects; or, rather, from *Umbria*, a country of Italy, whence it is used to be brought.

UMBILICAL, among anatomists, something relating to the umbilicus, or navel. See the articles **NAVEL** and **ABDOMEN**.

UMBILICAL POINTS, in mathematics, the same with foci. See **FOCUS**.

UMBILICUS, the navel, in anatomy. See the article **NAVEL**.

UMBONE, a name used by some for the style or pistil of a flower. See the articles **FLOWER**, **PISTIL**, &c.

UMBRA, or **SHADOW**. See **SHADOW**.

UMBRE, or **UMBER**, among painters. See the article **UMBER**.

UMBRELLA-TREE, in botany, a curious species of magnolia. It grows in Carolina to the height of sixteen or eighteen feet; the trunk is slender, and the wood is soft and spongy; the leaves are large, deciduous, and produced in horizontal circles, resembling an umbrella; whence the name: the flowers are composed of ten or eleven white petals, which hang down, and are afterwards succeeded by scarlet fruit of the same form with the other species of magnolia, and is increased from seeds in the same manner. See **MAGNOLIA**.

UMPIRE, a third person chosen to decide a controversy left to arbitration. See the article **ARBITRATION**.

UNCASING, among sportsmen, signifies the cutting up, or flaying of a fox.

UNCIA, in general, a Latin term denoting the twelfth part of any thing; particularly the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called an inch.

UNCIAE, in algebra, the numbers prefixed before the letters of the members of any power produced from a binomial, residual, or multinomial root. Thus, in the fourth power of $a+b$, viz. $a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4$, the unciae are 4, 6, 4; being the same with what others call co-efficients. See **BINOMIAL**, **INVOLUTION**, and **CO-EFFICIENT**.

UNCIAL, an epithet which antiquaries give to certain large sized letters or characters, anciently used in inscriptions and epitaphs. The word is formed from the Latin *uncia*, the twelfth part of any thing, and which in geometrical measure signified the twelfth part of a foot, viz. an inch, which was supposed to be the thickness of the stem of one of those letters.

UNCTION, *Unctio*, the act of anointing or rubbing with oil, or other fatty matter.

The cure of divers wounds, ulcers, &c. greatly depend upon repeated unctions with oil, unguents, cerats, &c. For the mercurial unction applied to bring on a salivation, see **SALIVATION**.

UNCTION, in matters of religion, is used for the character conferred on sacred things, by anointing them with oil.

Unctions were very frequent among the Hebrews.—They anointed both their kings and high-priests, at the ceremony of their inauguration. They also anointed the sacred vessels of the tabernacle and temple, to sanctify and consecrate them to the service of God. The manner of making the oil, or perfumed ointment, with which the priests, and the vessels of the tabernacle, were to be anointed, was revealed to Moses by God himself, who calls it “An holy anointing oil.” The most exquisite perfumes and balsams were ingredients in it. The ceremony of anointing and consecrating Aaron to the high-priesthood is recorded in scripture. The sacred oil was poured upon his head and ran down upon his beard, and to the skirts of his garment. The Rabbins have a conceit, that the oil was poured upon his head in the form of a cross, or of the Hebrew letter *Caph*. They add, that, as long as the ointment or perfume, composed by

Moses, lasted, they continued to anoint the succeeding high-priests therewith: but when that was all spent, they were only installed by the ceremony of the habit, or investing them with the pontifical ornaments. And they say, the Mosaic unction lasted till the Babylonish captivity. But the Christian writers are of opinion, that the unction of the high-priests continued to the coming of the true anointed, the Messiah. And it seems as if Moses intended its continuance, by his setting down so punctually the manner of its composition.

In the ancient Christian church, unction or anointing always accompanied the ceremonies of baptism and confirmation. Persons to be baptized were anointed with oil, before they went into the water. This unction was performed by a deacon for the men, and by a deaconess for the women. The design of it was to prepare them for their spiritual combat, in like manner as the athletes were anointed before they entered the lists. After the baptized person came out of the water, he was again anointed with oil, as the completion and confirmation of baptism. This was administered by the bishop, or some presbyter acting by his authority.

Extreme unction, or the anointing of persons in the article of death, was likewise practised by the ancient Christians, in compliance with that precept of St. James: “Is any sick among you? let him call for the elders of the church, and let them pray over him, anointing him with oil in the name of the Lord.”

The Romish church has advanced extreme unction to the dignity of a sacrament. It is administered to none but such as are afflicted with some mortal disease, or are in a decrepit age. It is refused to impenitent persons, as also to criminals sentenced to die, because they are not in a state of death by disease or any other infirmity. The parts to be anointed are, the eyes, the ears, the nostrils, the mouth, the hands, the feet, and the reins: but men only are anointed in the part last mentioned. The laity are anointed in the palms of the hands; but priests on the back of it, because the palms of their hands have been already consecrated by ordination.

When a dying person is to receive the sacrament of extreme unction, the priest prepares seven balls of cotton, to wipe the parts anointed; some crumbs of bread, to rub his fingers with, water to wash them, a napkin to wipe them, and a taper to light him during the ceremony. In entering the sick person's apartment, he bids peace to the house, and, having set down the vessel of holy oil on the table, he gives the dying person the cross to kiss. Then he sprinkles him with holy water, and exhorts him to repentance and confession of his sins. Before the ceremony of anointing is performed, all the persons present fall down upon their knees, and repeat the penitential psalms and litanies. Then the unction is performed in this manner: the priest dips the thumb of his right hand, and sometimes a little spatula, into the vessel, and anoints therewith the above-mentioned parts in the form of a cross. The clerk lights him with a consecrated taper, and holds a basin or dish in which the pieces of cotton are laid. The priest begins with anointing the sick man's eyes, saying, “May God, by his holy anointing, pardon you the sins you have committed by the eyes.” In like manner he proceeds to the other parts, carrying the form of words according to the part he anoints. The anointing being ended, the priest repeats some prayers, and, when he goes away, leaves a crucifix with the sick person, that the sight of the dying Saviour may administer some consolation to him.

UNCUTH, *Unknotun*, is used, in the ancient Saxon laws, for him that comes to an inn guest-wise, and lies there but one night, in which case his host is not bound to answer for any offence he committed, of which he was guiltless himself.

UNDECAGON, is a regular polygon, of eleven sides. See **POLYGON**.

UNDE, **UNDEE**, or **UNDEY**. See **WAVY**.

UNDER the Sea, in the sea-language. A ship is said to be so when she lies still, or waits for some other ships, with her helm lashed, or tied up a-lee.

U N D

UNDER CURRENTS, currents distinct from the upper or apparent currents of the seas.

Some naturalists conclude that there are in divers places under currents, which set or drive a contrary way from the upper current; whence they solve the remarkable phenomena of the sea's setting strongly through the Straights into the Mediterranean, with a constant current twenty leagues broad; as also, that running from the Euxine through the Bosphorus into the Hellespont, and thence into the Archipelago: they conjecture, that there is an under current whereby as great a quantity is carried out as comes in. To confirm this, it is observed, that between the north and south foreland, it is either high or low water upon the shore three hours before it is so off at sea; a certain sign, that though the tide of flood runs aloft, yet the tide of ebb runs under foot, or close by the ground. Yet Dr. Halley solves the currents setting in at the Straights without overflowing the banks, from the great evaporation, without supposing any under current. See SEA.

UNDER Chamberlain of the Exchequer, an officer that clears the tallies written by the clerk of the tallies, and reads the same, in order that the clerk of the pell and the comptrollers thereof may see their entries to be true: he likewise makes all searches for records in the treasury, and has the custody of domesday book.

UNDER Treasurer of England, was an officer said to be first created by king Henry VII. whose duty was to chest up the king's treasure at the end of every term, to note the content of the money in each chest, and see it carried to the king's treasury for the ease of the lord treasurer.

UNDERSTANDING, *Intellectus*, is defined by the Peripatetics to be a faculty of the reasonable soul, conversant about intelligible things, considered as intelligible. They also make it twofold, viz. active and passive. Active understanding, they hold that faculty of the soul by which the species and images of intelligible things are framed, on occasion of the presence of phantasms or appearances thereof. For maintaining the intellect to be material, they hold it impossible it should be disposed to think by any disproportionable phantasms of mere body, and therefore that it is obliged to frame other proportionate species of itself, and hence its denomination active.

Passive understanding, is that which receiving the species framed by the active understanding, breaks forth into actual knowledge. See the article KNOWLEDGE.

The moderns set aside the Peripatetic notion of an active understanding. The Cartesians define the understanding to be that faculty whereby the mind conversing with, and, as it were, intent on itself, evidently knows what is true in any thing not exceeding its capacity. The Corpuscular philosophers define the understanding to be a faculty expressive of things which strike on the external senses, either by their images or their effects, and so enter the mind. Their doctrine is, *nihil esse in intellectu quod non prius fuerit in sensu*; and to this doctrine Mr. Locke, and most of the latest English philosophers, subscribe. See IDEA.

Between the Cartesians and Corpuscularians there is this farther difference, that the latter make the judgment to belong to the understanding, but the former to the will. Hence, according to the most approved opinion of the Corpuscularians, the understanding has two offices, viz. perception and judgment; according to the Cartesians, it has only one, viz. perception. See the articles PERCEPTION, JUDGEMENT, and WILL.

UNDERSTANDING is also used for the act, exercise, or exertion, of this faculty, or the action whereby the mind knows things, or represents them in idea to itself.

UNDERTAKERS, were anciently such persons as were employed by the king's purveyors, and acted as their deputies. At present the name is chiefly used for upholders, or persons who furnish out funerals, and also for such who undertake any great work.

UNDERWOOD, *sub-bosus*, is coppice, or any wood that is not accounted timber.

U N G

In the cutting the underwood of coppices, when the stubs are great, they should be stubbed up, for they only take up a great deal of room, and send up few shoots, their cracks and holes letting in water, and usually half killing them. The taking up these should be performed in winter, and the spaces they leave will be soon occupied by young trees; if not, a long branch of some neighbouring tree may be laid down, and will soon send up a sufficient supply of suckers for the place.

In felling the underwood, it is always proper to leave young trees enough. The worst of these may be taken down the next fall, especially if any of them grow near a great tree that will be fit to fell the next season, because they may be spoiled by its fall. When trees are at their full growth, there are several signs of their decay, as the withering or drying of their top branches, their taking in water at some of their knots, their being hollow or discoloured, and their making but small shoots. If wood-peckers make holes in the body, it is a bad sign, and, according to the appearance of one or more of these symptoms, it is very proper to cut down the tree before it decays farther. Large and spreading trees in coppices are often of more mischief than advantage, as they spoil a great deal of the underwood by their droppings.

The owner of a coppice must be very careful, when he fells the wood standing, by the acre, to mark beforehand what standards are to be left, because otherwise the purchaser seldom fails to cheat him, by felling some of them. *Mortimer's Husbandry*.

UNDULATION, in physics, a kind of tremulous motion or vibration observable in a liquid, whereby it alternately rises and falls like the waves of the sea.

This undulatory motion, if the liquid be smooth and at rest, is propagated in concentric circles, as most people have observed upon throwing a stone, or other matter, upon the surface of a stagnant water, or even upon touching the surface of the water lightly with the finger or the like. The reason of these circular undulations is, that by touching the surface with your finger, there is produced a depression of the water in the place of contact. By this depression, the subjacent parts are moved successively out of their place, and the other adjacent parts thrust upwards, which lying successively on the descending liquid, follow it; and thus the parts of the liquid are alternately raised and depressed, and that circularly. When a stone is thrown into the liquid, the reciprocal vibrations are more conspicuous: here the water, in the place of immersion, rising higher by means of the impulse, or rebound, till it comes to fall again, gives an impulse to the adjoining liquid, by which means that is likewise raised about the place of the stone as about a center, and forms the first undulous circle; this falling again, gives another impulse to the fluid next to it, farther from the center, which rises likewise in a circle; and thus successively greater and greater circles are produced.

Undulatory motion is likewise applied to a motion in the air, whereby its parts are agitated after the like manner as waves in the sea; as is supposed to be the case when the string of a musical instrument is struck. This undulatory motion of the air is supposed the matter or cause of sound.

UNGELD, in our ancient customs, a person out of the protection of the law; so that if he were murdered, no geld or fine was to be paid, in the way of compensation, by him that killed him.

UNGUENT, or OINTMENT, *Unguentum*, in medicine and surgery, a topical remedy or composition, chiefly used in the dressing of wounds and ulcers.

Unguents are divided into simple and compound, though it so happens that some of the former are considerably compounded; and amongst the latter there are some simple unguents, and others very little compounded. Unguents, liniments, and cerates, are external forms applied on divers parts of the body, both to cure, to ease, and to relieve them. These only differ from each other in their consistence; with regard to which, unguents hold the medium, being stiffer than liniments, but softer than cerates. Oils are the bases of all the three, to which are added wax, axungia, and several parts

of

of plants, animals, and minerals, both on account of the virtues they furnish, and to give a consistence to the oils, and to keep them longer on the part, that they may have more time to act. See the articles CERATE and LINIMENT.

Any of the officinal plasters, diluted with so much oil as will reduce it to the thickness of stiff honey, forms an ointment; but further increasing the oil it becomes a liniment.

There are some considerable compositions of this form in the intention of emollients: and amongst the compound unguents there are some which take in a number of very warm aromatic ingredients, and seem designed for paralytic infirmities, and cases that require brisk attenuating applications. At the head of the emollient unguents, is the unguentum dialthææ; and among the attenuating ones, the most in esteem is the unguentum martiatum and nervinum. There are ointments also within the intention of strengtheners; and the next intention of any consequence for which we are provided by this form, and which seems as suitable to it as any, is against cutaneous foulnesses, as the itch, and such like distempers; and this seems to be the reason that there is such a choice of them now given. But though most of these have the reputation of great antiquity, and hold their places in abundance of officinal dispensaries down to the present, yet they are so uncleanly in use, that they are almost altogether fallen into neglect, unless in some of our hospitals; those which contain mercury being much more neat and efficacious for the same purpose. Some other things of this division are little else than oils wrought into ointments, by the exchange of oil for lard. Pomatums are also ranked among the number of unguents.

UNGUIS, a Latin term, signifying a nail of the hand or foot.

UNGUIS PANNUS, or PTERIGIUM, in medicine and surgery, a preternatural membrane formed upon the coats of the eye, so as to extend itself over the cornea and pupil, and obstruct the sight.

An unguis of the eye happens when the blood-vessels of the tendinous tunic in the corners of the eyes are turgid with blood, through an obstruction or inflammation. When this distemper encreases, there is a sort of carnosus web which covers the eye in whole or in part, insomuch that the eyes are offended with the light, and look red sometimes: the web is thin and white, sometimes thicker and more fleshy, rough, obscure and painful; nay, sometimes it becomes cancerous, which is incurable, and ought not to be touched. In the cure, this preternatural coat is to be removed or taken off by abstergent and gently corroding medicines, or by the hand of a surgeon.

The medicines in use are sugar-candy-honey, white wine, bone of the cuttle-fish, burnt hartshorn, and calcined egg-shells; as also water of eye-bright, the great celandine, and the fennel, in which crocus metallorum may be infused: particularly the gall of pike dissolved in a proper water; that is, two ounces to one of the gall. Some recommend a water distilled from the dung of young geese in April. If the disorder be obstinate, the juice of the greater celandine may be used diluted in fennel water. The following collyrium is proper: take of prepared lapis hæmatitis, half a scruple; of white vitriol, twenty-five grains; of myrrh and saffron, each five grains; of white sugar candied, one scruple. Reduce this mixture to a powder, and then mix it with equal parts of the water of roses, eye-bright, and fennel, and apply it to the eye with a feather, taking care not to injure the pupil. If these methods are insufficient for destroying the pellicle, it must then be extirpated; in order to which, the patient being in a proper posture, the surgeon takes the small hook (plate CXXXVI. fig. 11.) and endeavours to pass its point under the thickest and loosest part of the pellicle; and endeavours, by this means, to elevate it a little. In the next place he takes the needle *a* (fig. 12.) armed with a thread, and passing it under the pellicle, ties it with a double knot; and then fastening the two ends in a loop, (fig. 13.) he thereby attempts to make a gentle elevation. This done, he en-

deavours to separate the upper and lower margin of the membrane with a lancet, that he may afterwards cut off the rest immediately in a straight line near the lachrymal caruncle, by a pair of small and strait scissars: he then draws back the thread and membrane towards the cornea; and if it adheres any where to the eye, frees it by degrees with a scalpel or scissars; in doing which he must take care not to injure the cornea, and observe that no part of the membrane be left adhering to the eye, though it is better to have some part of the unguis adhering to the cornea, when the separation is difficult, than to wound the cornea and leave scars in it; because any small portion of the membrane left behind may be taken off afterwards by heating the eye with gentle escharotics.

UNGUIS, in anatomy, is applied to two bones of the nose, being as thin as scales, and resembling the nail; whence their name.

The unguis are the smallest bones of the upper jaw, and are situated near the great canthus of the eyes. Some authors call them ossa lacrymalia; others, orbitaria-ossa. They are contiguous to four other bones, viz. the coronal; that of the nose; the maxillary; and that part of the ethmoides which forms the orbit.

UNGUIS, among botanists, the narrow part where the petals are inserted, when several go to make up the flower, as the broader part towards the end is called bractea.

UNGUIS ODORATUS, the nail-like sweet shell, in pharmacy, a medicine famous among the ancients; but has, for a long time, been out of credit: and the consequence of the neglect that has been shewn it is the losing its real history, and the mistaking different substances of the same origin and nature, though the produce of different animals, for it. We call what we suppose to be the unguis odoratus of the ancients, blatta byzantia; the truth is, however, that our blatta byzantia, or sweet hoof, is not the same with the unguis odoratus of the ancients, though nearly allied to it. The true unguis odoratus of the ancients, is a thin, flat, testaceous substance, of an oblong or oval figure, rounded at both ends, and marked on the surface with three or four concentric circles, or oval lines: its colour is a dusky brown with some admixture of the orange, sometimes of a purplish tinge: its usual size is that of a full grown nail of a man's thumb, and its thickness about the same with that of the nail: it is tough, flexible, and elastic; and has no peculiar smell or taste. Besides this genuine unguis odoratus, they had another smaller kind: both are the opercula of shells of the murex kind frequent in the Red Sea. The blatta byzantia is also the operculum or cover of a murex, as well as the unguis odoratus; but it belongs to a different species of that genus: there are also two kinds of the blatta byzantia, which are naturally without smell and taste.

UNGULA, in geometry, the section of a cylinder cut off by a plane passing obliquely through the plane of the base and part of the cylindric surface.

UNICORN, *μονοκερας*, an animal, famous among the ancients, but looked on by the moderns as fabulous, denominated from its distinguishing characteristic of having one horn only, which is represented as five palms long, and growing in the middle of the forehead. It is also said to be about the size of a horse: its hair short, and of a darkish brown colour, very timorous, and therefore keeping mostly in the woods. Some will have it an amphibious animal, and its horn moveable at pleasure. Others make all its strength to consist in its horn; and add, that when pursued by the hunters, it precipitates itself from the top of the highest rocks, and pitches upon its horn, which sustains the whole effect of its fall, so that it receives no damage thereby. It is added, that it is wonderfully fond of chaste persons; and therefore, in order to take it, a virgin is placed in its way, whom, when the unicorn spies, he lies down by her, lays his head in her lap, and falls asleep; upon which, the virgin making a signal, the hunters come in and take the beast; which could never be caught by any other means, because it would either cast itself from a rock or die.

The unicorn is one of the supporters of the British arms. It is represented by heralds passant, and sometimes rampant. When in this last action, as in the British arms, it is properly said to be saillant. Argent, an unicorn sejant fable, armed and unguled, or, borne by the name of Harding.

UNICORN-FISH, in natural history, the name of a fish of the whale kind, remarkable for having a horn growing out at its nose, in the manner of the supposed unicorn's horn, as described by many too credulous authors.

The fish feeds on flesh, or other fish, and is not only found in the main sea, but sometimes gets up into large rivers. In the year 1636, there was a large one caught in the river Oste, near its discharging itself into the Elbe, in the duchy of Bremen; this place is four German miles from the sea. The skin of this fish was spotted with dark brown spots upon a white ground; the epidermis was transparent, and under it was another skin very thin and spotted; but the true skin was brown, and near an inch in thickness. On the top of the head there is only a semilunar hole, as in the porpoises; this hole opens into the two channels, which run through the skull to the palate, and are called the ductus hydrogogi. The people who examined this creature, were not able to find any aperture in the body for the discharge of the excrements; whence it has been generally believed, that the creature voids them through this passage in the head.

Authors have differed in the name of the process issuing from the head, some calling it a horn, others a tooth; for some are of opinion that it serves it to break the ice for air; but others pretend that it is an offensive weapon, with which it wounds the common whale, and other large fish; and that, when it has plunged it up to the head in the whale's body, it sucks the juices of that animal.

The fish was near twenty feet long, and about four feet in diameter. The horn stood on the forepart of the head, just above the mouth, and was six feet long, white like ivory, and curiously wreathed or twisted. The body was smooth and slippery, like that of an eel; the head, in proportion to the body, was small, not exceeding sixteen inches in length: the eyes not bigger than a sixpence. It had, on each side of the neck, two black fins, one above, another at a small distance; these were two feet long, of the breadth of a hand, and about half an inch in thickness. *Phil. Trans. N^o. 447.*

UNICORNU FOSSILE, fossil unicorn's horn, the name of a substance much used in medicine in some parts of the world, and which seems to have been very little understood by many who have written of it; but is now determined to be no other than a terrene crustaceous spar, not very different from the osteocolla, and other bodies of that genus called the cibdeloplasticum.

It is esteemed as a sudorific and astringent, and is given in fevers attended with diarrhoeas, with great success.

UNIFORM, denotes a thing to be similar, or consistent, either with another thing or with itself, in respect of figure, structure, proportion, and the like; in which sense it stands opposed to difform.

Thus the uniform flowers of plants, are such as are of the same figure all around, having their fore and back parts, as also their right and left parts, exactly alike.

UNIFORM MOTION, &c. See MOTION and EQUABLE.

UNIFORMITY, a similitude, or resemblance, between the parts of a whole; such is that we meet with in figures of many sides and angles respectively equal, and answerable to each other.

UNIOLA, in botany, a genus of plants, whose flower consists of a bivalvular glume, or husk; each valve is of a lanceolato-compressed figure, like those of the cup; the inner valve appears somewhat higher than the outer one: the stamina are three capillary filaments, topped with oblong linear antheræ: there is no pericarpium, but the corolla incloses the seed, which is single, and of an ovato-oblong figure.

UNION, a junction, coalition, or assemblage of two or more different things in one.

UNION, among painters, expresses a symmetry and agreement between the several parts of a painting; e. g. when there is a great deal of relation and connection between them, both as to the figuring and colouring; so that they apparently conspire to form one thing.

UNION, in an ecclesiastical sense, denotes a combining or consolidating of two churches into one: there are two kinds of this union, as when one church is made subject to another, and one parson is made rector of both; and where a conventual church is made a cathedral.

In case two churches were so small as that the tythes did not make a competent provision for each of the parsons, they might be united at common law before any act of parliament was made for that purpose.

By statute, there may be an union of two churches where they lie not above a mile distant from each other, and where the value of the one exceeds not six pounds a year in the king's books of first-fruits; which is done by the consent of the bishop, the patron, and incumbent.

Also, in cities or corporate towns, it is ordained, that the bishop, the patron, and the mayors, or chief magistrate of the place, &c. may unite parish-churches therein: yet, when the income of the church is above one hundred pounds per ann. there the major part of the parishioners are to agree to the same; and after the union, the patrons of those churches are to present by turns, &c. but, notwithstanding, each of the parishes continue distinct as to rates, charges, &c.

UNION, or The UNION, by way of eminence, is more particularly used to express the act whereby the two separate kingdoms of England and Scotland were incorporated into one, under the title of the kingdom of Great-Britain. This happy union, in vain attempted by king James I. was at length effected in the year 1707, by the general consent of the queen and the estates of each realm. The chief articles of this union are, That the two kingdoms shall be united into one kingdom, by the name of Great Britain: that they, in consequence thereof, be represented by one parliament, of which sixteen peers and forty-five commoners are to be elected for Scotland, and have the same privileges with those of England: that the subjects of either nation shall have equal freedom of trade, and be liable to the same customs, and the like laws for public government, &c.

The kirk, or church of Scotland, is confirmed; and the courts of justice are to remain the same as they were before the union, yet subject to regulation, &c.

A court of exchequer is also erected in Scotland, to be a court of record, revenue, and judicature for ever; and barons of the said court are appointed, who shall be the judges there, &c.

UNISON, in music, the effect of two sounds which are equal in degree of tune, or in point of gravity and acuteness.

Unison may be defined a consonance of two sounds produced by two strings, or other bodies, of the same matter, length, thickness, tension, &c. equally struck, and at the same time: so that they yield the same tone or sound.

Unison is the first and greatest of concords, and the foundation of all the rest, according to Aristoxenus and most of the ancients: yet some deny it to be any concord at all, maintaining it to be only that in sounds which unity is in numbers.

Others restrain the word concord to intervals, and make it include a difference of tune; but this is precarious: for as the word concord signifies an agreement of sounds, it is certainly applicable to unisons of the first degree.

But though unisonance, or an equality of tune, makes the most perfect agreement of sound, it is not true, that the nearer any two sounds come to an equality of tune, they are the more agreeable. The mind is delighted with variety; and the reason of the agreeableness or dis-

agreeableness of two sounds must be ascribed to some other cause than the quality or inequality of the number of their vibrations. It is a famed phenomenon in music, that an intense sound being raised, either with the voice or sonorous body, another sonorous body near it, whose tune is either unison or octave to that sound, will sound its proper note, unison or octave, to the given note. The experiment is easily tried by the strings of two instruments, or by a voice and harpsichord; or a belt, or even a drinking-glass.

This our philosophers account for thus; one string being struck, and the air put in motion thereby, every other string, within the reach of that motion, will receive some impression therefrom: but each string can only move with a determinate velocity of recourses or vibrations; and all unisons proceed from equal or equidiurnal vibrations; and other concords, from other proportions. The unison string then, keeping equal pace with the sounding string, as having the same measure of vibrations, must have its motion continued, and still improved, till its motion become sensible, and it gives a distinct sound. Other concurring strings have their motion propagated in different degrees, according to the frequency of the coincidence of their vibrations with those of the sounded string; the octave, therefore, most sensibly: then in the fifth; after which the crossing of the motions prevents any effect.

This they illustrate by the pendulum, which, being set a-moving, the motion may be continued, and still improved, and augmented, by making frequent, light, coincident impulses; as blowing on it when the vibration is just finished: but if it be touched by any cross or opposite motion, and this too frequently, the motion will be interrupted and cease altogether. So of two unison strings, if the one be forcibly struck, it communicates motion by the air to the other: and being equidiurnal in their vibrations, that is, finishing them precisely together, the motion of the other will be improved and heightened by the frequent impulses received from the vibrations of the first; because given precisely, when that other has finished its vibration and is ready to return: but if the vibration of the chords be unequal in duration, there will be a crossing of motions less or more, according to the proportion of the inequality; by which the motion of the untouched string will be so checked as never to be sensible. And this, we find, is the case in all consonances, except unison, octave, and the fifth.

UNIT, UNITE, or UNITY, in arithmetic, the number one, or one single individual part of discrete quantity.

UNITED NETHERLANDS consist of the provinces of Holland, Zealand, Friesland, Groningen, Overijssel, Gelderland, with Zutphen and Utrecht; these are bounded by the German sea on the north and west; by the circle of Westphalia on the east, and by Flanders, Brabant, and the dutchy of Cleves on the south; lying between 3 deg. 20 min. and 7 deg. 30 min. east long. and between 57 deg. 35 min. and 52 deg. 40 min. north lat. being about fifty miles long, and as many broad, including the Zyder-sea, which takes up a considerable space between these limits.

UNITY, in poetry.—The critics require three unities to be observed in every regular play, viz. those of action, time, and place.

By the unity of action they mean, that one great action is to be carried on throughout the play, on which all the under actions must depend, and which they must all have a tendency to promote. For, say they, if two actions be equally laboured and driven on by the poet, the unity of the piece will be destroyed, and it will no longer be one play, but two. The action must also have a beginning, middle, and end; which F. Bossu, a celebrated French critic, thus explains: The causes and designs of undertaking an action, are the beginning; the effects of those causes, and the difficulties met with in the execution of it, are the middle; and the unravelling and removing these difficulties, is the end.

By unity of time, strictly speaking, is meant, that all the transactions represented in a play, may naturally be supposed to have passed in as little time as is taken up in

the representation. This rule indeed is very seldom observed by dramatic poets; and the critics are not agreed about the matter, some allowing twenty-four hours, others twelve, and others but four or five, for the time of the action. But, as every play ought to be a just imitation of nature, the greater the likeness in this particular, as well as others, the more perfect the piece must be esteemed.

What is meant by unity of place, is, that the scene should never be shifted throughout the play, but remain in the same place where it was laid at the beginning. This indeed would be to keep close to nature and probability; for what is presented on the same stage, which is never moved, should be supposed to have passed in the same house, and the same apartment. But, as this restraint would cramp the poet too much, and would suit very ill with abundance of subjects, the unity of place is allowed to be sufficiently observed, if the action is confined to the same town or city: the scene, however, ought never to be changed in the middle of an act. In general, the French, in imitation of the ancients, observe this law more strictly than the English; but the more judicious and accurate of our writers take care not to deviate too far from probability, by shifting the scene between the acts much farther than the persons concerned may be supposed to have gone in the interval, and therefore seldom carry it out of the same town. Others have no regard at all to unity of place; and most of our great Shakespear's plays are faulty in this respect.

UNITY, *Unitas*, the abstract, or quality, which constitutes, or denominates a thing *unum*, or one.

The school philosophers generally define unity, by a thing's being undivided in itself, and divided from every thing else. Others, more accurately, define it a mode of being, whereby it agrees to any particular being, once: these make two kinds of unity, viz. unity of simplicity, which is both undivided and indivisible; such as that of God, angels, and human souls: the other union of composition, which, though undivided, is divisible in the being, as consisting of divers parts: such is that of man, &c.

Hence, unity is also divided into that per se, which agrees to any being whose parts are collected into one substratum; and unity per accidens, whose parts are not united into one substratum; as that of a flock of sheep, &c.

Some also make a singular, or numerical unity, and an universal unity; a real, and an imaginary, unity, &c.

It is disputed among mathematicians, whether or no unity be a number? The generality of authors hold the negative, and make unity to be only inceptive of number, or the principle thereof; as a point is of magnitude, and an unison of concord.

Stevinus is very angry with the maintainers of this opinion: and yet, if number be defined a multitude of units joined together, as many authors define it, it is evident that unity is not itself a number.

UNITY, among divines.—The Romanists and the reformed dispute, whether or no the church be one single body, all the members of which are joined together, either really, or in inclination; so that whatever does not appertain to that body, is no part of the church: which is what they call the unity of the church; and which the Romanists maintain to be restrained to one single society, or one communion, under one visible head; and out of which the protestants are excluded! These last, on the contrary, hold, that the unity of the church may still subsist without the members being united under any one visible head; it being sufficient, that all Christians be united by the bonds of mutual love and charity; and that they be agreed in the fundamental points of religion.

All the difficulty is, to fix what those fundamentals are; some inclining to make the door of the church wider than others.

UNIVALVE *Shells*, in natural history, a term used to express one of the three general classes of shell fish; the other two are the bivalves and multivalves. The univalve shells are those which consist only of one piece, not of two or more joined together.

UNIVERSAL, something that is common to many things; or it is one thing belonging to many, or all things.

In logic, universal is either complex or incomplex. A complex universal is either an universal proposition, as every whole is greater than its part; or whatever raises a manifold conception in the mind, as the definition of a reasonable animal. An incomplex universal, is what produces only one conception in the mind, and is a simple thing respecting many; as human nature, which relates to every individual wherein it is found.

UNIVERSALITY, that quality which denominates a thing universal. See the preceding article.

UNIVERSE, a collective name, signifying the whole world, or the assemblage of heaven and earth with all things therein.

As space is, in its own nature, every way infinite; it gives us an idea of the infinity of the universe, which can therefore be only in part comprehended by us: and that part of the universe which we can have any notion of, is that which is the subject of our senses; and of this the eye presents us with an idea of a vast extended prospect, and the appearance of various sorts of bodies disseminated through the same.

The infinite abyss of space, which the Greeks call *το πᾶν*, the Latins *inane*, and we the universe, does undoubtedly comprehend an infinity of systems of moving bodies round one very large central one, which the Romans call *sol*, and we the sun. This collection of bodies is therefore properly called the solar system, and sometimes the mundane system, from the Latin word *mundus*, the world. See the article SYSTEM.

That the universe contains as many solar systems, or worlds, as there are what we call fixed stars, seems reasonable to infer from hence, that our sun, removed to the distance of a star, would appear just as a star does, and all the bodies moving about it would disappear entirely. Now, the reason why they disappear, is because they are opaque bodies, and too small to be seen at so great a distance, without an intense degree of light; whereas theirs is the weakest that can be, as being first borrowed, and then reflected to the eye. See the article STAR.

But the sun, by reason of his immense bulk and innate light, which is the strongest possible, will be visible at an immense distance; but the greater the distance, the less bright it will appear, and of a lesser magnitude: and therefore every star of every magnitude, may probably be a sun like our own, informing a system of planets, or moving bodies, each of which may be inhabited like our earth, with various kinds of animals, and stored with vegetable and other substances.

We can perceive, says Mr. Mac Laurin, no bounds of the vast expanse in which natural causes operate; nor can we fix any border or termination of the universe; and we are equally at a loss to trace things to their elements, and to discover the limits which inclose the subdivisions of matter.

The objects, which we commonly call great, vanish when we contemplate the vast body of the earth: the terraqueous globe itself is soon lost in the solar system; being in some parts seen as a planet, or distant star; and in great part of the system unknown, or visible only at rare times to vigilant observers, assisted perhaps with instruments like our telescopes. The sun itself dwindles into a star: Saturn's vast orbit, and the orbits of all the comets, croud into a point, when viewed from numberless places between the earth and the nearest fixed star. Other suns illuminate other systems, where our sun's rays are unperceived; but all these also are swallowed up in the vast expanse of the universe. Even all the systems of the stars that sparkle in the clearest sky, must possess a small corner only of that space over which such systems are dispersed. And after we have risen so high, and left all definite measures so far behind us, we find ourselves no nearer to a term or limit; for all this is nothing to what may be displayed in the infinite expanse, beyond the remotest stars that ever have been discovered.

In this view of the universe, an august idea arises in the mind, worthy of the infinite and wise Author of nature, who can never be supposed to have created so many glorious orbs, to answer so trifling a purpose as the twinkling to mortals by night now and then; besides that, the far greatest part of the stars are never seen by us at all, as has been shewn under the article STAR, which see.

UNIVERSITY, *Univerſitas*, a collective term, applied to an assemblage of several colleges, established in a city, or out-town, wherein are professors in the several sciences, appointed to teach them to students; and where degrees or certificates of study in the divers faculties are taken up.

In each university four faculties are usually taught; theology, medicine, law, and the arts and sciences.

They are called universities, or universal schools, by reason the four faculties are supposed to take in the whole compass of study.

In the eye of the law, an university is held a mere lay body, or community; though, in reality, it be a mixed body, composed partly of laymen, and partly of ecclesiastics.

Universities had their first rise in the XIIth and XIIIth centuries. Those of Paris and Bologna pretend to be the first that were set on foot; but then they were on a different footing from the universities among us.

Our own universities, of Oxford and Cambridge, seem entitled to the greatest antiquity of any in the world; and Baliol and Merton colleges, in Oxford, and St. Peter's in Cambridge, all made colleges the XIIIth century, may be said to be the first regular endowments of this kind in Europe. For though University college in Cambridge had been a place for students ever since the year 872, yet this, like many of the ancient colleges beyond sea, and Leyden to this day, was no proper college; but the students, without any distinction of habit, lived in citizens houses, having only meeting-places to hear lectures and disputes.

In after times, there were houses built for the students to live in society; only each to be at his own charge, as in the inns of court: these, at first, were called inns, but now halls. At last, plentiful revenues were settled on several of these halls, to maintain the students in diet, apparel, &c. and these were called colleges. See COLLEGE.

The universities of Oxford and Cambridge are governed next under the king, by a chancellor, who is to take care of the government of the whole university, to maintain the liberties thereof, &c. Under him is the high-steward, whose office is to assist the chancellor and other officers, when required, in the execution of their offices, and to hear and determine capital causes, according to the laws of the land, and the privileges of the university. The next officer is the vice-chancellor, who officiates for the chancellor in his absence.

There are also two proctors, who assist in the government of the university, particularly in the business of school exercise, taking up degrees, punishing violators of the statutes, &c. Add to these, a public orator, keeper of records, register, beadles, and verger.

The universities of Scotland are four, viz. those of St. Andrew, Aberdeen, Edinburgh, and Glasgow. In Ireland there is only one university, viz. that of Dublin.

UNIVOCAL, in the schools, is applied to two or more names, or terms, that have but one signification, in opposition to equivocal, which is where one term has two or more significations.

Our univocal terms are such, whose name, as well as nature, is the same, in opposition to equivocals, whose names are the same, but their natures very different.

The ancients believed that all perfect animals were produced by univocal generation; that is, by the sole union or copulation of a male and female of the same species or denomination; and that insects were produced by equivocal generation, without any seed, and merely of the corruption of the earth, exhaled, and, as it were, impregnated, by the sun's rays: but this doctrine of insects is now exploded.

UNLAWFUL, illegal, something prohibited by, or contrary to, the terms of law, either divine or human.

UNLAWFUL ASSEMBLY, the meeting of three or more persons together, by force to commit some unlawful act, as to assault any person, to enter his house or land, &c. and thus abiding together, whether they attempt the execution or not.

UNLIMITED, or **INDETERMINATE PROBLEM**, is such a one as is capable of infinite solution. See **PROBLEM**.

UNMOOR, a term used at sea: when a vessel which was riding at anchor weighs the same, or gets it up, in order to sail, they say she is unmooring.

VOCABULARY, *Vocabularium*, in grammar, denotes the collection of the words of a language, with their significations, otherwise called a dictionary, lexicon, or nomenclature. See the article **DICTIONARY**, &c.

A vocabulary is properly a lesser kind of dictionary, which does not enter so minutely into the origins and different acceptations of words.

VOCAL, something that relates to the voice or speech: thus vocal music is that set to words, especially verses, and to be performed by the voice, in contradistinction to instrumental music, composed only for instruments, without singing. See the article **VOICE**, **VERSE**, &c.

VOCATIVE, in grammar, the fifth state or case of nouns.

When we name the person we are speaking to, or address ourselves to the thing we are speaking of, as if it were a person, the noun, or name, requires a new relation, which the Latins and Greeks express by a new termination, called the vocative; as from *Dominus*, a Lord, is formed the vocative *Domine*, O Lord.

In English, and most of the modern languages, the vocative is expressed in nouns that have an article in the nominative, by omitting that article; as *The Lord is my hope*; *Lord, thou art my hope*; though, on many occasions, we use an interjection.

VOICE, *Vox*, a sound produced in the throat and mouth of an animal, by an apparatus of instruments for that purpose. See **SOUND**.

Voices are either articulate or inarticulate. Articulate voices are those of which several conspire together to form some assemblage or little system of sounds; such are the voices expressing the letters of an alphabet, numbers of which joined together, form words. Inarticulate voices are such as are not organized, or assembled into words; such is the barking of dogs, the braying of asses, the hissing of serpents, the singing of birds, &c.

The formation of the human voice, with all the varieties thereof observed in speech, music, &c. makes a very curious article of inquiry; and the apparatus and organism of the parts administering thereto, is something exceedingly surprizing. Those parts are the trachea or wind-pipe, thro' which the air passes and repasses into the lungs; the larynx, which is a short cylindric canal at the head of the trachea; and the glottis, which is a little oval cleft or chink left between two semicircular membranes stretched horizontally within the larynx; which membranes, though capable of joining close together, do generally leave an interval, either greater or less, between them, called the glottis.

The long canal of the trachea, terminated at top with the glottis, appears so like a flute, that the ancients made no doubt but the trachea contributed the same to the voice, as the body of the flute does to the sound of that instrument. Galen himself fell in some measure into the mistake; he perceived indeed, that the principal organ of the voice was the glottis, but he still allowed the trachea a considerable share in the production of the sound.

Galen's opinion was followed by all the ancients after him, and even by all the moderns before M. Dodart: but that author observes, that we do not either speak or sing when we inspire or take in the air, but only when we expire or expel it; and that the air coming out of the lungs, passes always out of the minuter vesicles of that part into larger, and at last into the trachea itself, which

is the largest of all: that thus its passage becoming still more free and easy, and thus more than ever in the trachea, it can never undergo such a violence, and acquire such a velocity in that canal, as is required to the production of sound: but that as the aperture of the glottis is very small, in comparison with the width of the trachea, the air can never get out of the trachea by the glottis, without a vast compression and augmentation of its velocity; and that by this means in passing, it communicates a brisk agitation to the minuter parts of the two lips of the glottis, and gives them a kind of spring, and occasions them to make vibrations, which communicated to the passing air, are what really occasion the sound. The sound thus formed, proceeds into the cavity of the mouth and nostrils, where it is reflected and resounds: and on this resonance, M. Dodart shews, it is that the agreeableness of the voice intirely depends. The different consistences, forms, &c. of the divers parts of the mouth, contribute to the resonance, each in their way; and from this mixture of so many different resonances in their due proportion, there results an harmony in the human voice inimitable by any musician.

Hence it is that when any of these parts are disordered, e. g. when the nose is stopped, the voice becomes displeasing. This resonance in the cavity of the mouth, does not seem to consist in a simple reflexion, such as that of a vault, &c. but in a resonance proportionate to the tones of the sound sent into the mouth from the glottis; and accordingly we find this cavity to lengthen and shorten itself according to the depth or acuteness of the tone.

As the organs that form the voice make a kind of wind instrument, one might imagine to find some provision therein answerable to that which produces the difference of tone in some other wind-instruments. The tone, therefore, must be attributed, either to the mouth and nostrils, which occasion the resonance, or to the glottis, which produces the sound: and as all the different tones are produced in man by the same instrument, it follows, that the part which produces them, must be capable of changes answerable thereto. The different apertures of the lips of the glottis, it is proved, produce all the different tones in the several parts of music, and the manner is thus. The voice, it is shewn, can only be formed by the glottis, but the tones of the voice are modifications of the voice, and these can only be produced by the modifications of the glottis. Now the glottis is capable only of one modification, which is the mutual approach or recess of its lips; it is this, therefore, produces the different tones. Now that modification includes two circumstances; the first and principal is, that the lips are stretched more and more from the lowest tone to the highest: the second is, that the more they are stretched, the nearer they approach. From the first, it follows, that their vibrations will be so much the quicker, as they come nearest their highest tone: and that the voice will be just, when the two lips are equally stretched; and false, when unequally; which agrees perfectly well with the nature of string instruments. From the second, it follows, that the higher the tones are, the nearer will they approach to each other, which agrees perfectly well with instruments governed by reeds or plugs.

The degrees of tension of the lips, are the first and principal cause of tones, but their differences are insensible; the degrees of approach are only consequences of that tension, but their differences are more easily assigned. They are different apertures that produce, or at least that accompany, different tones, both in natural wind instruments, and artificial ones; and the diminution of the aperture raises the tones both of the glottis, and the reed.

VOICE, in grammar, a circumstance in verbs, whereby they come to be considered as either active or passive, i. e. either expressing an action impressed on another subject, as, *I beat*, or receiving it from another, as, *I am beaten*.

The Greeks have a third voice called the medial voice, thus denominated, because it has sometimes an active

active and sometimes a passive signification: though generally it is of an active signification. With regard to the termination of this medial voice, it is to be observed, that the present and imperfect tenses are the same with those of the passive voice; or, in other words, when these tenses of the passive voice are taken actively, they are then denominated of the medial voice.

VOICE, in matters of election, denotes a vote or suffrage.

In this sense a man is said to have a deliberate voice, when he has a right to give his advice and opinion in a matter of debate, and his suffrage is taken. An active voice, when he gives his vote for the election of any one; and a passive voice, when the suffrages may fall on himself to be elected. An excitative voice, when he may act to procure another to be elected. A consultative voice, when he can only offer reasons and remonstrances, whereon the chief or head determines at his own discretion.

VOID SPACE, in physics. See the article **VACUUM**.

VOID and **VOIDABLE**, terms frequently used in our law; as a thing that is done contrary to law at the time of the doing, it is said to be void, and no person shall be bound thereby. But where a thing is only voidable, and not void, though it be what the person that did it ought not to have done, yet when it is done, the doer cannot avoid the same, notwithstanding by some act in law it may be void in his heir, &c. It has been held, that the bond of an infant, or one non compos mentis, is void, because the law has not appointed the doing any thing to avoid such bonds. A lease for term of life, which is voidable, must be made void by re-entry, &c. and a deed is generally avoided by special pleading.

VOIDANCE, or **VACANCY**, in the canon law, a want of an incumbent upon a benefice, &c.

VOIDED, in heraldry, is understood of an ordinary whose inner or middle part is cut out, leaving nothing but its edges to shew its form, so that the field appears through it. Hence it is needless to express the colour or metal of the voided part, because it must of course be that of the field. The cross voided, differs from the cross fimbriated, in that the latter does not shew the field through it, as the other does; and the same obtains in other ordinaries.

VOIDER, in heraldry, one of the ordinaries whose figure is much like that of a flask of flanch, only that it does not bend so much.

VOIDING, or **EVACUATING**, in medicine. See **EVACUATION**.

VOL, among heralds, signifies the two wings of a fowl joined together, borne in armoury, as being the whole that makes the flight. Accordingly, a demi-vol is a single wing.

VOLA, the palm, or inside of the hand, comprehended between the fingers and the wrist.

VOLANT, in heraldry, is when a bird in a coat of arms is drawn flying, or having its wings spread open.

VOLATILE, in physics, is commonly used to denote a mixed body whose integral parts are easily dissipated by fire or heat; but it is more properly used for bodies whose elements or first component parts are easily separated from each other, and dispersed in air. For as any mixed body is said to be fixed in a double sense, so may it be said to be volatile two ways; whence the same body, e. gr. mercury, is both volatile and fixed at the same time; since, as its integral parts, or those which still retain the nature of mercury, are easily separable by fire, and readily flies away, it is said to be volatile; and yet as it is very difficult to destroy its contexture, and resolve it by fire, or any other menstruum, into its first elements, it is said to be fixed; the same may be said of sulphur, antimony, &c.

Minerals, for the generality, are less volatile than vegetables, and vegetables are less so than animals. The chemists distinguish greatly between volatile salts and fixed salts. The capitals of aludels stop and collect the

volatile parts of substances, in sublimation, and make what we call flowers.

The particles of fluids which do not cohere very strongly together, says Sir Isaac Newton, and are of such a smallness as renders them most susceptible of those agitations which keep liquors in a fluor, are most easily separated and rarified into vapour; and, in the language of the chemists, they are volatile, rarifying with an easy heat, and condensing with cold. But those which are grosser, and by that means less susceptible of agitation, or cohere by a stronger attraction, are not separated without a stronger heat, or perhaps not without fermentation; these are what the chemists call fixed bodies.

When the fire decomposes any mixed body, the parts most disposed to receive a great motion are soonest loosened, and rise up in the order which the differences of that disposition give them, the rest remaining immovable at the bottom of the vessel. Those that rise first are called volatile parts; such are phlegm, oil, spirits and salts, both urinous and alcalous. The parts remaining, viz. earth and lixivial salts, are called fixed.

VOLATILISATION, or **VOLATILIZATION**, the act of rendering fixed bodies volatile, or of resolving them by fire into a fine subtle vapour or spirit, which easily dissipates and flies away. All bodies, even the most fixed, as gold, may be volatilized; either of themselves, or with the admixture of some volatile substance, or spirit, by distillation or sublimation.

VOLCANO, or **VULCANO**. See the article **VULCANO**.

VOLLEY, a military salute, made by discharging a great number of fire-arms at the same time.

VOLT, or **VOLTE**, in the manege, a round or circular tread; and hence, by the phrase, to make volts, is understood a gait of two treads, made by a horse going sideways round a center, in such a manner, that these two treads make parallel tracts, one larger, made by the fore-feet, and another smaller, made by the hind-feet, the croup approaching towards the center, and the shoulders bearing outwards.

Sometimes the volt is of one tread; as when a horse makes volts in corvets, and in caprioles, so that the haunches follow the shoulders, and move forwards on the same tread.

In general, the way and tract of a volt is made sometimes round, sometimes oval, and sometimes square, of four straight lines; so that these treads, whether round or square, inclose a terrain, or manege ground, the middle of which is sometimes distinguished by a pillar, or else by an imaginary center, which is there supposed in order to regulate the distances and the justness of the volt.

A demi-volt is a demi-round of one or two treads, made by the horse at one of the corners of the volt, or else at the end of the line of the passade; so that being near the end of this line, or one of the corners of the volt, he changes hands, to return by a semi-circle.

A renversed volt is a tract of two treads, made by the horse, with his head to the center, and his croup out; so that he goes sideways upon a walk, trot, or gallop, and traces out a small circumference with his shoulders, and a larger one with his croup.

This different situation of the shoulders and the croup, with respect to the center, gave this volt the name of renversed, as being opposite in situation to the former.

VOLUBILIS, in botany, a name used by Dillenius for a species of convolvulus. See the article **CONVOLVULUS**.

VOLUME, *Volumen*, in matters of literature, a book, or writing, of a just bulk to be bound by itself. The name is derived from the Latin *volvere*, to roll up; the ancient manner of making up books being in rolls of bark or parchment.

Foreign philosophers use the phrase, volume of a body, for its bulk, or the space contained within its superficies.

VOLUNT, *Voluntas*, in law, is when a tenant holds land, &c. at the will of the lessor, or lord of the manor,

VOLUNTARY, in music, a piece played by a musician, extempore, according to his fancy. This is often used before he begins to set himself to play any particular composition, to try the instrument, and to lead him into the key of the piece he intends to perform.

VOLUNTEERS, in the military art, persons who, of their own accord, and at their own expence, serve in the army.

VOLUTA, in natural history, a genus of univalve shells, with an oblong mouth, a clavicle sometimes erect and sometimes depressed, and sometimes coronated at top.

To this genus belong the admiral-shells, tiger-shells, &c.

VOLUTE, *Voluta*, in architecture, a kind of spiral scroll, used in the Ionic and Composite capital: whereof it makes the principal characteristic and ornament.

There are several diversities practised in the volute. In some, the list or edge, throughout all the circumvolutions, is in the same line or plane; such are the antique Ionic volutes, and those of Vignola. In others, the spires or circumvolutions fall back; in others, project and stand out. Again, in others, the circumvolutions are oval; in others, the canal of one circumvolution is detached from the list of another by a vacuity or aperture. In others, the rind is parallel to the abacus, and springs out from behind the flower thereof. In others, it seems to spring out of the vase from behind the ovum, and rises to the abacus, as in most of the fine Composite capitals.

VOLVULUS, in medicine, a name which some authors give to the iliac passion, by others called chordap-fus, and by others miserere mei.

VOMER, in anatomy, a bone of the upper jaw, situated between the bones of the palate and the sphenoidal bone, being also joined to the process of the ethmoides, and part of the lower jaw, and having its fore part, which is spongy, continued to the middle cartilage of the nose, and making, in conjunction with it, the septum nasi.

VOMICA, in medicine, is commonly taken for a suppurated imposthume, or an abscess with a suppuration.

The vomica pulmonum is a latent disease of the lungs, which often deceives under a shew of health. What goes by this name, is a small abscess seated in some part of the lungs, and straitly inclosed within a bag or membrane. This disorder is most incident to those who are afflicted with a tabes, or labour under an anastomosis or rupture of a vein in the lungs. In this disease, the breath smells ill long before the vomica breaks; sometimes blood comes up with coughing, the body is perfectly dull and heavy, and the cough very long and troublesome, and sometimes followed by an expectoration of the vomica, in which case the patient is seized with no small fever, succeeded by bloody spit, and a vast perturbation of body; the consequence of which circumstance may possibly be a recovery to a good state of health. It has often happened that the vomica, by a sudden rupture, has occasioned sudden and unexpected death.

VOMIT, or **EMETIC**, in pharmacy. See the article **EMETIC**.

VOMITING, in medicine, a retrograde spasmodic motion of the muscular fibres of the oesophagus, stomach, and intestines, attended with strong convulsions of the muscles of the abdomen and diaphragm, which, when gentle, create a nausea; when violent, a vomiting. These convulsive disorders proceed from the immoderate quantity, or acrimony of the food; from poisons; from some injury of the brain, as a wound, contusion, compression, or inflammation of that part, from an inflammation of the diaphragm, stomach, intestines, spleen, liver, kidneys, pancreas, or mesentery; from an irritation of the gula; from a disorderly motion of the spirits, by unaccustomed agitations in a coach, ship, or otherwise, or from the idea of some thing nauseous.

The two principal curative indications to be observed are, first, to quiet and compose the convulsive and un-

ruly motion of the stomach: and, secondly, to oppose and subdue the material causes of the disorder.

The first intention is answered by corroborating and antispasmodic medicines, such as saffron and castor, with the testaceous powders, as coral, crabs-claws, and oyster-shells; powders, composed of cinnamon, the leaves of mint, nutmeg, orange peel, calamus aromaticus, and other such simples, are also of great service. And if anodynes are found necessary, the storax pill, or Sydenham's laudanum, are to be given.

While these medicines are taken internally, there may also be applied outwardly, to the region of the stomach, such things as have power to repress its disorderly motions; of this kind are the oil of mint, nutmeg, and the like, with balsam of Peru: these oils may be reduced to a proper consistence, with this balsam, for the spreading on leather, and laying on for some time. Hungary water, and other the like spirits, are of great use also, rubbed on with the hand; and to these may be added yeast, and the strongest wine-vinegar applied hot to the part. Finally, an excellent application is balsam of Peru alone, reduced to the consistence of a cataplasm, with crumb of bread. The methods to be used to remove the material causes of the vomiting, are next to be considered: if it be of the pituitous kind, and owing to crudities in the primæ viæ, and a viscid mucus sticking to them, it is best cured by an emetic: if the vomiting of itself be found not sufficient to carry off the fordes which occasion it, and the patient continues, after the fits of vomiting, afflicted with a nausea and heart-burn; in this case, a large quantity of warm water, with a little butter, may serve the purpose; or if this be found insufficient, a dose of ipecacuanha is to be given.

VOMITING of blood, *vomitus cruentus*, a very dangerous kind of hæmorrhage, consisting in a bringing up by vomit of pure and unmixed blood from the stomach, and being a method used by nature to throw off a portion of the blood, which molests the whole in the vena porta, and by that means to facilitate the circulation of the rest of the mass.

This distemper sometimes arises from internal causes, and is regularly periodical, observing the stated times of the eruptions of the menses, or other natural discharges; sometimes it arises from accidents, such as the giving of violent purging or emetic medicines, or corrosive ones. Among the preceding signs of this disorder, are to be reckoned a sensation of straitness and anxiety in the præcordia, with tension, and involuntary sighs; with a nausea or sickness of the stomach, and a straining to vomit; which is more violent than in vomiting on any other occasion; after this the blood is thrown up pure, and the vomiting then ceases, till, after a plain sensation of more blood being collected in the stomach, the efforts to discharge it in the same manner are again renewed. The quicker the blood is thrown up, after its being discharged into the stomach, the more fluid and more florid it appears; the longer it is detained there, the blacker and thicker it appears.

A vomiting of blood is but an uncommon disorder. It more frequently attacks women than men; among the female sex it is principally seen in those whom the menses have left too early in life, or who have had violent suppressions of them for a long time. In men, this distemper seldom seizes any but those who have been used to periodical discharges from the hæmorrhoidal vessels, and who have had them suddenly stopped; and they are then usually first attacked with violent pains in the left hypochondrium. People of scorbutic habits, and such as have had quartan agues of long standing, have been sometimes thus affected. And, beside these natural causes, people of all ages and sexes may vomit blood, from external injuries.

A vomiting of blood is ever a dangerous disorder; for though the quantity of blood thrown up is seldom so great as to occasion immediate death, yet it generally degenerates into a tabes in men, and into a cachectic habit in women. It is less dangerous to young women, than to any other persons; and when it is periodical, especially when it observes the time of the menstrual discharges, is much less dangerous than under any other circumstances.

stances. During the paroxysm, the proper medicines are powder of nitre, cinnabar, and the absorbent substances, such as crab's-eyes, or the like, and afterwards bleeding, cupping, and gentle purges; and diaphoretics are to be given for some time.

VORTEX, in meteorology, a whirlwind, or sudden, rapid, or violent motion of the air in gyres or circles.

Vortex is also used for an eddy or whirlpool; or a body of water, in certain seas or rivers, which runs rapidly around, forming a sort of cavity in the middle.

An artificial **VORTEX**, expressive of the phenomena of the natural ones, may be made with a cylindric vessel, placed, immoveable, on a horizontal plane, and filled to a certain height with water. In this water a stick being plunged, and turned round as briskly as may be, the water is necessarily put into a pretty rapid circular motion; and rises to the very edge of the vessel; and when there arrived, ceases to be further agitated.

The water thus raised, forms a cavity in the middle, whose figure is that of a truncated cone; its base is the same with the upper cavity of the vessel; and its vertex is the axis of the cylinder.

What raises the water at the side of the vessel, which occasions the cavity in the middle, is its centrifugal force. For the motion of the water being circular, it respects a centre taken in the axis of the vessel; or, which is the same, in the axis of the vortex formed by the water, the same velocity then being impressed on all the water, the circumference of a smaller circle of water, or a circle less remote from the axis, has a greater centrifugal force than another that is greater, or more remote from the axis. The smaller circle, therefore, drives the greater towards the side of the vessel; and from this pressure, or impulsion, which all the circles receive from the smaller ones that precede them, and convey to the greater which follow them, arises that elevation of the water along the edge of the vessel to the very top, where we suppose the motion to cease.

With a vortex thus formed, M. Saulmon, of the Royal Academy of Sciences, made divers experiments, by putting several solid bodies therein, to acquire the same circular motion; with intent to discover which of them, in making their revolutions round the axis of the vortex, approach toward, or recede from it, and with what velocity. The result was, that the heavier the body, still the greater was its recess from the axis.

M. Saulmon's view in this attempt, was, to shew how the laws of mechanics produce the celestial motions; and that it is probably to those motions that the gravity or weight of bodies is owing. But, unhappily, the experiments shew just the contrary of what they should do, to confirm the Cartesian doctrine of gravity.

VORTEX, in the Cartesian philosophy, is a system or collection of particles of matter moving the same way, and round the same axis.

Such vortices are the grand machines, whereby those philosophers solve most of the motions and other phenomena of the heavenly bodies. Accordingly, the doctrine of these vortices makes a great part of the Cartesian philosophy.

The matter of the world, they hold to have been divided at the beginning into innumerable little equal particles, each endowed with an equal degree of motion, both about its own centre and separately, so as to constitute a fluid.

Several systems, or collections of this matter, they further hold to have been endowed with a common motion about certain points, as common centres, placed at equal distances; and that the matters moving round these, composed so many vortices.

Then the primitive particles of the matter they suppose, by these intestine motions, to become, as it were, ground into spherical figures, and so to compose globules of divers magnitudes; which they call the matter of the second element; and the particles rubbed, or ground off them, to bring them to that form, they call the matter of the first element.

And since there would be more of this first element than would suffice to fill all the vacuities between the

globules of the second, they suppose the remaining part to be driven towards the center of the vortex, by the circular motion of the globules; and that being there amassed into a sphere, it would produce a body like the sun.

This sun being thus formed, and moving about its own axis with the common matter of the vortex, would necessarily throw out some parts of its matter, through the vacuities of the globules of the second element constituting the vortex; and this especially at such places as are farthest from its poles; receiving at the same time by these poles, as much as it loses in its equatorial parts. And, by this means, it would be able to carry round with it those globules that are nearest, with the greater velocity; and the remoter, with less. — And by this means, those globules which are nearest the center of the sun, must be smallest; because, were they greater, or equal, they would, by reason of their velocity, have a greater centrifugal force, and recede from the center. If it should happen that any of these sun-like bodies, in the centers of the several vortices, should be so incrustated, and weakened, as to be carried about in the vortex of the true sun: if it were of less solidity, or had less motion than the globules towards the extremity of the solar vortex, it would descend towards the sun, till it met with globules of the same solidity, and susceptible of the same degree of motion with itself; and thus, being fixed there, it would be for ever after carried about by the motion of the vortex, without either approaching any nearer to, or receding from the sun; and so would become a planet.

Supposing then all this, we are next to imagine, that our system was at first divided into several vortices, in the center of each of which was a lucid spherical body; and that some of these being gradually incrustated, were swallowed up by others which were larger, and more powerful, till at last they were all destroyed, and swallowed up by the biggest solar vortex; except some few which were thrown off in right lines from one vortex to another, and so become comets.

But this doctrine of vortices is at best, merely hypothetical. It does not pretend to shew by what laws and means the celestial motions are really affected, so much as by what means they possibly might, in case it should have so pleased the Creator. But we have another principle which accounts for the same phenomena, as well, nay, better, than that of vortices; and which we plainly find has an actual existence in the nature of things; and this is gravity, or the weight of bodies.

The vortices then should be cast out of philosophy; were it only that two different adequate causes of the same phenomena are inconsistent.

But we have other objections against it. For, 1. If the bodies of the planets and comets be carried round the sun in vortices, the bodies of the parts of the vortex immediately investing them, must move with the same velocity, and in the same direction; and besides, must have the same density, or the same vis inertiae. But it is evident that the planets and comets move in the very same parts of the heavens, with different velocity and in different directions. It follows, therefore, that these parts of the vortex must revolve at the same time in different directions, and with different velocities; since one velocity and direction will be required for the passage of the planets, and another for that of comets.

2. If it were granted that several vortices were contained in the same space, do penetrate each other, and revolve with divers motions; since those motions must be conformable to those of the bodies which are perfectly regular, and performed in conic sections; it may be asked, how they should have been preserved entire to so many ages, and not disturbed nor confounded by the adverse actions and shocks of so much matter as they meet withal?

3. The number of comets is very great and their motions perfectly regular, observing the same laws with the planets, and moving in conical orbits, which are exceedingly excentric. Accordingly they move every way, and to all parts of the heavens, freely pervading the planetary regions, and going frequently contrary to the order

order of the signs; which would be impossible, unless these vortices were away.

4. If the planets move round the sun in vortices, those parts of vortices next the planets, we have already observed, would be equally dense with the planets themselves, consequently, the vortical matter, contiguous to the perimeter of the earth's orbit, would be as dense as the earth itself: and that between the orbits of the earth and Saturn, it must be as dense or denser. For a vortex cannot maintain itself, unless the more dense parts be in the center, and the less dense towards the circumference; and, since the periodical times of the planets are in a sesquialterate ratio of their distances from the sun, the parts of the vortex must be in the same ratio. Whence it follows, that the centrifugal force of the parts will be reciprocally as the squares of the distances. Such, therefore, as are at a greater distance from the center, will endeavour to recede therefrom with the less force. Accordingly, if they be less dense, they must give way to the greater force, whereby the parts nearer the center endeavour to rise. Thus the more dense will rise, and the less dense descend; and thus there will be a change of places, till the whole fluid matter of the vortex be so adjusted, as it may rest in æquilibrium.

Thus will the greatest part of the vortex without the earth's orbit, have a degree of density and inactivity, not less than that of the earth itself. Whence the comets must meet with a very great resistance, which is contrary to all appearances.

The doctrine of vortices, Sir Isaac Newton observes, labours under many difficulties: for a planet to describe areas proportional to the times, the periodical times of the vortex should be in a duplicate ratio of their distances from the sun; and for the periodical time of the planet to be a sesquuplicate proportion of their distances from the sun, the periodical times of the parts of the vortex should be in the same proportion of their distances: and, lastly, for the lesser vortices about Jupiter, Saturn, and the other planets, to be preserved, and swim scarcely in the sun's vortex, the periodical times of the parts of the sun's vortex should be equal. None of which proportions are found to obtain in the revolutions of the sun and planets around their axis.

Besides, the planets, according to this hypothesis, being carried about the sun in ellipses, and having the sun in the umbilicus of each figure, by lines drawn from themselves to the sun, do always describe areas proportionable to the times of their revolutions; which that author shews the parts of no vortex can do.

Again, Dr. Keil proves, in his Examination of Burnet's Theory, that if the earth were carried in a vortex, it would move faster in the proportion of three to two, when it is in Virgo, than when it is in Pisces; which all experience proves to be false.

VOTE, the suffrage or resolve of each of the members of an assembly, where any affair is to be carried by a majority; but more particularly used for the resolves of the members of either house of parliament. See **PARLIAMENT**.

VOTIVE MEDALS, those on which are expressed the vows of the people for the emperors or empresses. See **MEDAL**.

VOUCHER, in law, is a person called into court, to make good another's warranty, who is either to defend the right against the demandant, or yield him other lands to the value, &c.

This extends to lands or tenements of freehold or inheritance, but not to any thing personal or mixed.

Here he that voucheth is called the voucher, and the person that is vouched is called the vouchee. There is also a foreign voucher when the tenant impleaded in a particular jurisdiction, voucheth one to warranty in some other county, out of the jurisdiction of that court, and prays that he may be summoned.

Voucher also signifies a receipt or acquittance in cases of account.

VOW, a solemn and religious promise, or oath.

The use of vows is found in most religions. They made a considerable part of the pagan worship; being made, either in consequence of some deliverance, under

some pressing necessity, or for the success of some enterprise.

The use of vows is observable throughout the history of the Old Testament. When Jacob went into Mesopotamia, he vowed to God the tenth of all he possessed, and promised to offer it at Beth-el, to the honour of God. Jephthah's vow, and the fatal consequences of it to his family, are well known. Samuel was vowed, or devoted, to the service of the Lord. The Levitical law is very particular in laying down rules concerning the observation of vows; the substance of which, as understood and practised by the Jews, is as follows.

All vows were to be voluntary: nevertheless, if a person, who was wholly in his own power, made a vow, in a thing lawful and possible, and promised something solemnly to God, either by a simple vow, or the addition of a solemn curse, he was obliged to fulfil his vow: otherwise he was liable to be punished by God for the robbery and injustice offered him. If he appointed no particular time for accomplishing his vow, he was bound to do it instantly, lest, by delay, he should prove less able, or be unwilling to execute his promise, or perhaps forget it. If the thing devoted chanced to be lost, during the delay, he was obliged to give the value of it.

Though no human power could absolve or acquit from lawful vows once made, yet there were persons appointed to judge, whether they were lawful or not, and to determine concerning their obligation: and, as a modern writer informs us, there is a traditional doctrine among the Jews, practised at this day, that if any person makes a vow, which afterwards he wishes unmade and repents of, and it be not to the prejudice of any third person that it should be broken; in this case, he may go to a rabbin, or to any other three men, who, hearing the reasons of his repentance, and approving them, have power to free him from the obligation, by saying, "Be thou absolved from this vow;" and so he is discharged. But this casuistical solution is expressly contrary to the letter of the law, which insists upon the strict execution of vows in things lawful; for which reason the Jewish doctors very prudentially advise their scholars not to accustom themselves to vows, and be content to obey the precepts of the law, without laying any other bonds upon themselves.

All persons, who bound themselves by vows, were supposed to be absolutely at their own disposal, and under no power, that had authority to make them void. Sons in the family of their father, and undisposed of in marriage, and servants under the government of their masters, had no power to vow, without the express consent of their superiors.

But the Mosaic law is most explicit in directing women in the nature and execution of vows. It considers them in a threefold state; before they are married, after marriage, and in their widowhood. If a maiden, in the family and under the government of her father, made a simple vow, or bound it by an oath, and her father, being acquainted therewith, did not disallow her promise, she was obliged by her vow, and it was not in his power afterwards to disannul it: but if the father, upon notice of her vow, refused his consent, though she had bound it with an oath, it was entirely void, and she contracted no guilt by her not performing it.

When a married woman, or one espoused to a husband, though still in her father's house, made a vow; her husband, under whose power she then was, was to determine concerning it; and the case was exactly the same as that of a daughter under the authority of her father. If the husband, after he had consented, refused the woman the liberty of fulfilling her vow, she was acquitted, and the guilt lay wholly at his door.

A widow, or a woman divorced, though she returned to her father's house, who by that means might be supposed to recover his ancient right over her, yet remained perfectly at her own disposal, and was obliged to stand to her vows.

The matter of these vows of women seldom extended to the devoting any part of their goods to the service of the priests, or other sacred purposes; but consisted generally

nerally in abstaining from such and such meats, though in themselves lawful; or in binding themselves to fast upon other days, as well as upon the great day of expiation, which was the only fast ordained by the law of Moses. And this kind of vow was called a vow of prohibition or obligation.

There was another sort of vow, called a vow of consecration, that is, when any thing was devoted to the service of the altar, the temple, or the priests, in which this distinction was observed, that, when a thing was devoted simply in such words as these, "Let this thing be a devoted thing," it was always understood to be set apart wholly for the priests: but when there was an addition, that determined it to a certain use, as in this manner, "Let this be a thing devoted, offered by me, to holy uses;" the thing devoted was then employed about the reparation of the temple, the sacred vessels, the garments of the priesthood, or other holy purposes.

The vow of consecration admitted of several degrees. The highest is what the law calls a singular or extraordinary vow, when a man vowed himself, or his children, wholly to the service of God in the tabernacle; it being thought a singular instance of devotion and piety, to assist the priests in the meanest offices, such as bringing in wood, carrying out ashes, sweeping away the dust, and the like. However persons, thus devoted, were not admitted to any part of the holy service: but a value was set upon them by the priest, which was employed to holy uses. The reason, why God would not accept of the persons themselves, as they desired, but the value of them for his service, seems to be, because there was a sufficient number of persons peculiarly designed for the service of the tabernacle. But that the priest might not either overvalue or undervalue any person, the law has expressly fixed the rates which he should demand for their redemption. A man, from twenty years old to sixty, was to be redeemed for fifty shekels of silver. This was the highest value, and not without reason; for from twenty to sixty, men are the most able to do service. Women, under the same restriction for age, were not able to be so useful as men; and therefore they were valued at no more than thirty shekels.

A parent had power to devote a child to the service of God. If the child was a male, between the age of five years and twenty, the price of redemption was twenty shekels; if a female, she was redeemed for ten. A child was not capable of being devoted before it was a month old: but then it might; and the price between that age, and five years old, was five shekels for the male, and three for the female. A man beyond sixty was redeemed for no more than fifteen shekels, because his labour then is almost past, and his life likely to be short: a female was redeemed for ten.

If a person was so poor as not to be able to pay the prices of redemption abovementioned, the priest was to examine into his circumstances and abilities, and, upon the best information, to set such a rate upon him, as he was able to pay, without injuring himself or his family.

If a man vowed a clean beast to divine use, he had no power to alter it for any other beast or thing: if he presumed to change what he had vowed, he was to be beaten, and both the beasts were reputed holy. A devoted beast, that was unclean, and not fit for sacrifice, was to be valued by the priest; and if the man who vowed it, was willing, he might redeem it at the price set upon it: but it was in his choice, either to leave the beast with the priest, or to pay the money set upon it.

Nothing vowed had the benefit of redemption, but what was set apart by a simple vow only: whatever was devoted with a cherem, or a curse upon him that vowed, if he did not fulfil his engagement, remained irreversibly and unalterably to the use to which it was sanctified; and the person was accursed, who applied it to any other purpose. Such devoted things were called most holy, and no one might touch them but the priests; and they were so strictly applied to divine service, that they could not be alienated either by sale, redemption, commutation, donation, or any other way.

The Sanhedrim, or the whole congregation, had a power to devote their enemies to death, before they went to war with them, and such of their own people who refused to obey the military laws. In this case, there was no redemption allowed; but the persons so devoted were put to death.

Under the New Testament we see the practice of vows. St. Paul made a vow of Nazariteship, when he left the harbour of Cenchrea, in order to go to Jerusalem. And, when he arrived at Jerusalem, St. James advised him to join himself with four Judaizing Christians, who had made the like vow.

Pilgrimages, and other acts of devotion, among Christians, have, in all ages, been undertaken in consequence of vows; and the monastic life is supported thereby, the religious obliging themselves, by solemn vows, to chastity, poverty, obedience, and other observances.

The practice of devoting one's self to the service of some saint was formerly much in vogue, and is still practised in several catholic countries. A yearly tribute was paid to the patron-saint; and the vassal often bound himself and his whole posterity, or at least his children.

VOWS, *Vota*, among the Romans, signified sacrifices, offerings, presents and prayers made for the Cæsars and emperors, particularly for their prosperity and the continuance of their empire. These were at first made every five years, then every fifteen, and afterwards every twenty, and were called quinquennialia, decennialia, and vincennialia.

VOWEL, *Vocalis*, in grammar, a letter which affords a complete sound of itself, or a letter so simple as only to need a bare opening of the mouth to make it heard, and to form a distinct voice.

The vowels are six in number, viz. A, E, I, O, U, Y, and are called vowels in contradistinction to certain other letters, which, depending on a particular application of some part of the mouth, as the teeth, lips, or palate, can make no perfect sound without an opening of the mouth, that is, without the addition of a vowel, and therefore called consonants.

Grammarians reckon also eight semi-vowels, viz. F, H, L, M, N, R, S, Z, so denominated because they approach nearer a vowel in the pronunciation. Of these semi-vowels four, viz. L, M, N, R, are called liquid.

UPLAND, denotes high ground, or, as some call it, terra firma, by which it stands opposed to such as is moorish, marshy, or low.

The uplands lie either on the tops of hills, or on their sides, or on the slopes of rising grounds. They sometimes have a sandy soil, sometimes a rocky, gravelly, or loamy one; and sometimes they consist of tough clay, or a black mould. They are used by the farmers either for grazing or corn, as they happen to be more moist or more dry; and this difference depends upon their situation and nature.

Those lands which lie flat upon the tops of hills are usually the driest, and those which form the slopes or sides are usually the moistest, because of the wet that is continually oozing through them. The chalky, and especially the clayey soils in these places, are most of all subject to be wet, especially in winter, because they retain the moisture a long time; though they have also the inconveniencies of the sandy and rocky lands in the same situations, chapping in summer. The black mould, and the hazely loams in these places, are the best for corn, as well as for pasture, especially if the latter escapes the common misfortune of being full of worms. These lands neither are washy in winter, nor parch up in summer.

The upland meadows have some disadvantages, as they often need mending or feeding, which those that lie lower do not; but then they make amends for this in their hay, which is always much finer and sweeter than that of the low-lands.

UPLOPER, a name given to one particular species of pigeon, called by Moore *columba gutturosa faliens*.

It was first brought to England from Holland, and much resembles that kind of pigeon called the English powder, but that it is smaller: its crop is very round, and in this it buries its bill. Its legs are very small and slender, and its toes are short, and close together, on which it treads so nicely, that, when moving, any small thing might be put under the ball of its foot. The pigeons of this species are generally all blue, all black, or all white, seldom or never pied. They are very scarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word *oplopen*, which signifies to leap up; and it was thus named from its manner of approaching the hen, which is always by leaping upon her. *Moore's Columbarium*.

UPRIGHT, in architecture, a representation or draught of the front of a building, called also an elevation or orthography.

UPRIGHT, in heraldry, is used in respect of shell fishes, as crevices, &c. when standing erect in a coat. Inasmuch as they want fins, they cannot, according to Guillim, be properly said to be hauriant; that being a term appropriated to scaly fishes.

UPUPA, the hoopoe, in ornithology, a genus of birds with the beak arcuated, convex, compressed, and equal, and having a furrow running along each side of it; there is a crest on the head, which is capable of folding back. This is an extremely singular bird, but it is so thick covered with feathers, that it appears large in proportion to its weight; the head is large, and ornamented with an elegant crest; the eyes are small, but very bright and piercing; the tail is between four and five fingers breadth long, in the middle of which there is an elegant spot of white, of the figure of a new moon; the back is variegated with black and white in an elegant manner; the legs are short, and the outer toe is connected to the middle one some part of the way down, without the help of a membrane.

URACHUS, in anatomy, a membranous canal in the foetus of quadrupeds in general, of a pyramidal figure, extended immediately from the fundus of the bladder to the navel, and after passing through this, it is by degrees enlarged, and makes its way into the allantois at right angles each way, or nearly so, and conveys the urine from the bladder into the cavity of this membrane. In the human foetus, the whole urachus is not pervious, or very rarely so; it is usually found solid, in form of a ligament. It scarce appears probable, therefore, that it serves the office of discharging the urine from the bladder in this as in the former case, and especially as there is no such membrane as the allantois in the human body, nor any cavity formed for the reception of so great a quantity of fluid.

URANOSCOPUS, the star-gazer, in ichthyology, a species of trachinus, with numerous cirri on the under jaw.

This fish is of an extremely singular figure; the body is round, a little depressed, the back broad, the sides prominent, and the belly somewhat flattened; the head is large and depressed; the mouth divided, as it were, into three spines under the tongue, and the lower jaw turning upwards; the eyes are large, and stand near one another, not on the sides, but on the top of the head, so that the fish naturally looks straight upwards; the iris is of a gold yellow, the pupil is of a bluish black, the nostrils have each a double aperture, and are placed at some distance under the eyes; the whole head, and the coverings of the gills, are beset with a great number of rough and sharp tubercles; there are two back fins, the first has three prickly rays, the second has fourteen; the pectoral fins have each sixteen rays, the ventral ones have each five, and the pinna ani has thirteen.

URDE, or *Urdée*, in heraldry. A cross *urde* seems to be the same with what we otherwise call *chleche*, or *chlechee*.

URED, the blasting or blighting of trees or herbs. See **BLIGHT**.

It is sometimes used by physicians for an itching or burning of the skin.

URETERS, *ουρητρες*, in anatomy, two membranaceous tubes or pipes, nearly cylindric in figure, and of about the thickness of a quill: but their diameter is very uncertain.

They arise from the kidneys, one from each, and terminate in the urinary bladder. At their origin in the kidneys, they are expanded into the form of a funnel, and this expansion makes the pelvis of the kidneys. See the article **PELVIS**.

At their termination, which is in the hinder and lower part of the bladder, they pass obliquely in between its membranes, and open into the bladder by very narrow orifices, and can admit nothing into them from the bladder. They are not straight, but somewhat bent, so as to resemble the letter S; their substance is membranaceous, and they are composed of three coats: the first, a common one, from the peritonæum; the second, a thin muscular one; and the third, a nervous one, covered with a lubricous humour; and in this there are sometimes discovered glands. The blood vessels and nerves come from the adjacent parts.

The use of the ureters is to receive the urine secreted in the kidneys from the pelvis, and to carry it to the urinary bladder. When these are obstructed, a suppression of urine is the consequence; for there is no other way for the urine to get into the bladder but through them. They are often found of an unnatural size, owing to stones concentered from among the urine.

URETHRA, *ουρηθρα*, in anatomy, a membranaceous tube or canal, of a cylindric figure, arising from the neck of the bladder, and continued to the pudendum, serving to discharge and carry off the urine and semen.

The length of the urethra is very different in both sexes. In man it is twelve or thirteen inches, from the neck of the bladder to the extremity of the glans. It is situated in a kind of narrow furrow, formed between the corpora cavernosa, in the bottom or lower part of the penis. It does not run perfectly straight, but is bent in a very singular manner. Its cavity is as large as that of a goose quill.

It is composed of two robust membranes, an exterior and interior; their substance is thin and tough, and between them there is a spongy or cavernous matter, in which some authors pretend to have discovered glands, but this is uncertain.

The bulb of the urethra is that part of it next to the prostate; it is much thicker than the rest of the tube, and is about an inch long, and in some measure resembles a walnut. It is of a thick and spongy texture.

The interior surface of the urethra is full of roundish and oblong foraminulae and furrows, out of which there may often be pressed a thick viscous fluid, the use of which is to lubricate the urethra, and to defend it from the acrimony of the urine. See **PENIS**, &c.

The urethra or urinary passage in women, usually called *meatus urinarius*, is situated straight under the clitoris, and shews itself by a little eminence. Its length is about two fingers breadth; its diameter is greater than that in man, but somewhat narrower at the end than elsewhere. It is capable of great dilatation. There are in it certain little ducts, which convey to its inner surface a mucous humour, for lubricating and defending it from the acrimony of the urine, like those in man; but their origin is uncertain.

URIM and **THUMMIM**, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral, or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus and several others maintain, that it meant the precious stones set in the high-priest's breast-plate, which, by some extraordinary lustre, made known the will of God to those who consulted him.

Spencer believes, that the urim and thummim were two little golden figures shut up in the pectoral, as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim, as there are particular authors that wrote about them.

The

The safest opinion, according to Broughton, seems to be, that the words *urim* and *thummim* signify some divine virtue and power, annexed to the breast-plate of the high-priest, by which an oracular answer was obtained from God when he was consulted by the high-priest; and that this was called *urim* and *thummim*, to express the clearness and perfection which these oracular answers always carried with them; for *urim* signifies light, and *thummim*, perfection; these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident.

The use made of the *urim* and *thummim* was to consult God, in difficult cases, relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons.

It is usually of glass, and crooked; and sometimes it is filled with milk to assuage the pain of the gravel.

URINAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician. See the preceding article.

URINARIA FISTULA, the urinary passage, or urethra. See **URETHRA**.

URINE, *Urina*, a serous and saline fluid, of a citron colour, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is, from time to time, emitted thence by the canal of the urethra.

The urine is therefore the serosity of the blood, but not pure, for it is loaded with saline, sulphureous, and terrestrial particles, of which it is the menstruum and the vehicle. The sides of the bladder are guarded by a mucilaginous fluid, excreted by the glands which are between its coats, by which means the urinous salts make the less impression upon it. This fluid forms the glair, which falls to the bottom of the vessel when a person is afflicted with the stone.

It is observable, that there are three sorts of substances differently placed in the urine, viz. the *nubecula*, the *encœrema*, and the *hypostasis*. The *nubecula* is a sort of pellicle which swims on the top of the urine, and consists of the saline and fibrous particles of the blood mixed with the serosity. When it is exposed to the fire, it changes to a crustaceous substance. The *encœrema*, or suspension, is a white, light, spongy matter which swims in the middle of the urine, consisting of particles of a different nature. The *hypostasis*, or sediment, is a saline, sulphureous, and terrestrial matter, which precipitates to the bottom of the urine.

The urine of four-footed beasts is troubled and muddy, that of men is more clear and limpid. In infants it is more pale and thick than that of middle aged persons. In the very old it is more clear, thin, and has not so much colour. In hot, bilious constitutions, it is more of a saffron colour: in the cold and pituitous, pale. Wine-drinkers have it of a higher colour, and more thick: in those that use much exercise it is little and red: in the idle it is pale, with a large sediment. After meals it is copious, insipid, light, raw, and without smell: after long fasting, it is of a higher colour, acrid, and little. Those that sweat much make little water, which is more muddy and yellow. Diseases cause a remarkable change in the urine. Light, thin, watery urine, shews the person to be afflicted with internal spasms, the hysteric passion, the hypochondriac pains, the cardialgia, the stone or gravel, or convulsive colic. In diseases of the head, such as the vertigo, phrensy, madness, melancholy, and epilepsy, the urine is always thin and light. It is likewise the same in the more grievous afflictions of the nerves from poison or worms. This state of the urine not only happens in the fits, but some days before and after.

When the urine is thin, aqueous, and always white, it presages danger in obstinate diseases: if it is copious in the state of fevers, and before the crisis, it portends a

phrensy. In internal inflammations it is always dangerous, the more copious the worse. After a dysentery, a spotted fever, or the small-pox, this kind of urine is common. In a cachexy, leucophlegmatia, enormous bleedings in the beginning of an anasarca, in the green-sickness, in a suppression of the menses, the urine is crude, turbid, pale, greenish, or of a light citron-colour, and copious. In all preternatural febrile heats, the urine is yellow or red, and in small quantities: such kind of urine as is more or less red, or thin and light, or thick and heavy, is usually in intermitting and continual fevers. In the fit, that is, in its exacerbation or state, the urine is thin, clear, and without sediment. In an ardent and bilious fever, the urine is generally pellucid, but of a flame-colour. In intermittents after the fit, and on the well day, it is thick, and deposits a sediment. If this happens in continual fevers after the crisis, it shews the fever to be ended. If the sediment is of a roty or purple-colour, it shews the blood is in fault, as is evident in continual fevers. When it is intensely yellow, it discovers that the bile is in fault. When it is brown or black, there is plenty of black bile, as in a scorbutic or miliary fever, and in quartans of a dangerous nature. When it is very plentiful, and full of viscid and crude humours, in replete, obese, and spongy bodies, it shews the obstinacy of an intermitting fever.

As it is a good sign when the urine is thick and deposits a sediment, in fevers; so, on the contrary, if there is no sediment in intermitting fevers, but the urine continues clear, and lets fall no sediment in the cold fit, it is a very bad sign. If, after the fit, it has no sediment, but is pellucid, it is a very bad omen. In all inflammatory fevers, if the urine is clear and of a purple colour, or brown, and of a deep colour, frothy and without sediment, it is a bad sign. Likewise, it is always observed, that in a continual fever, if the urine is turbid, and does not grow clear either by the fire or rest, nor deposits a sediment, it is a very dangerous presage; it is likewise very bad, when in continual fevers, it is thick on the first days, and in the remainder, especially the critical days, it is thin and without sediment. In the decline of catarrhal fevers, and in the small-pox and measles, if the urine was clear and aqueous, but is now thick and high-coloured, with a sediment, it is a certain sign that the disease remits.

In consumptions, and all other violent and chronical diseases, if the urine is thick, high-coloured, and a dark red, with a copious sediment, and a fatness swims upon the urine, and adheres to the sides of the urinal, the body at the same time wasting away, it is a sign of a slow hectic fever, which is generally fatal. The like danger is threatened when in dropical persons the urine is like that of hectic, for its scarcity is a sign that the lymph is extravasated into some cavity or porous substance; and if the colour is of a deep red, with a gross sediment, it shews the intestine motion and heat dissolves the blood, that the liver is obstructed; whence a bilious *fordes* is separated therefrom.

In chronical diseases, without a fever, when the urine is thick, high-coloured, and of a reddish brown, as well as heavy, as in the confirmed scurvy, gout, scorbutic palsy, and in extreme old age, as also in a nephritic passion, when the pains cease, as well as in the yellow and black jaundice, it shews a plenty of saline and sulphureous excrementitious parts, wherewith the blood and humours abound, and are not duly secreted therefrom, by reason of an obstruction of the liver. Willis has observed, that patients dying of the scurvy have had their livers almost without blood, and like a cow's udder. In some the gall-bladder was either empty or full of stones, or very bitter filth.

When the urine is thick, of a deep colour, and dyes linen yellow, it is a sign that the bile is obstructed, or the duct constricted with a spasm, whence the passage of the bile into the duodenum is hindered: whence it regurgitates by the lymphatic vessels into the blood and lymph, and produces a jaundice, which proceeds from an impeded secretion of the bile in the liver.

Sometimes the urine is imbued with an oily matter, and is made without noise, there are various colours on

It was first brought to England from Holland, and much resembles that kind of pigeon called the English powder, but that it is smaller: its crop is very round, and in this it buries its bill. Its legs are very small and slender, and its toes are short, and close together, on which it treads so nicely, that, when moving, any small thing might be put under the ball of its foot. The pigeons of this species are generally all blue, all black, or all white, seldom or never pied. They are very scarce in England, and in Holland have been valued at five and twenty guineas a pair.

They have their name from the Dutch word *oplopen*, which signifies to leap up; and it was thus named from its manner of approaching the hen, which is always by leaping upon her. *Moore's Columbarium.*

UPRIGHT, in architecture, a representation or draught of the front of a building, called also an elevation or orthography.

UPRIGHT, in heraldry, is used in respect of shell fishes, as crevices, &c. when standing erect in a coat. Inasmuch as they want fins, they cannot, according to Guillim, be properly said to be hauriant; that being a term appropriated to scaly fishes.

UPUPA, the hoopoe, in ornithology, a genus of birds with the beak arcuated, convex, compressed, and equal, and having a furrow running along each side of it; there is a crest on the head, which is capable of folding back. This is an extremely singular bird, but it is so thick covered with feathers, that it appears large in proportion to its weight; the head is large, and ornamented with an elegant crest; the eyes are small, but very bright and piercing; the tail is between four and five fingers breadth long, in the middle of which there is an elegant spot of white, of the figure of a new moon; the back is variegated with black and white in an elegant manner; the legs are short, and the outer toe is connected to the middle one some part of the way down, without the help of a membrane.

URACHUS, in anatomy, a membranous canal in the foetus of quadrupeds in general, of a pyramidal figure, extended immediately from the fundus of the bladder to the navel, and after passing through this, it is by degrees enlarged, and makes its way into the allantois at right angles each way, or nearly so, and conveys the urine from the bladder into the cavity of this membrane. In the human foetus, the whole urachus is not pervious, or very rarely so; it is usually found solid, in form of a ligament. It scarce appears probable, therefore, that it serves the office of discharging the urine from the bladder in this as in the former case, and especially as there is no such membrane as the allantois in the human body, nor any cavity formed for the reception of so great a quantity of fluid.

URANOSCOPUS, the star-gazer, in ichthyology, a species of trachinus, with numerous cirri on the under jaw.

This fish is of an extremely singular figure; the body is round, a little depressed, the back broad, the sides prominent, and the belly somewhat flattened; the head is large and depressed; the mouth divided, as it were, into three spines under the tongue, and the lower jaw turning upwards; the eyes are large, and stand near one another, not on the sides, but on the top of the head, so that the fish naturally looks straight upwards; the iris is of a gold yellow, the pupil is of a bluish black, the nostrils have each a double aperture, and are placed at some distance under the eyes; the whole head, and the coverings of the gills, are beset with a great number of rough and sharp tubercles; there are two back fins, the first has three prickly rays, the second has fourteen; the pectoral fins have each sixteen rays, the ventral ones have each five, and the pinna ani has thirteen.

URDE, or *Urdée*, in heraldry. A cross *urdé* seems to be the same with what we otherwise call *chleche*, or *chlechee*.

URED, the blasting or blighting of trees or herbs. See **BLIGHT**.

It is sometimes used by physicians for an itching or burning of the skin.

URETERS, *ουρητιδες*, in anatomy, two membranaceous tubes or pipes, nearly cylindric in figure, and of about the thickness of a quill: but their diameter is very uncertain.

They arise from the kidneys, one from each, and terminate in the urinary bladder. At their origin in the kidneys, they are expanded into the form of a funnel, and this expansion makes the pelvis of the kidneys. See the article **PELVIS**.

At their termination, which is in the hinder and lower part of the bladder, they pass obliquely in between its membranes, and open into the bladder by very narrow orifices, and can admit nothing into them from the bladder. They are not straight, but somewhat bent, so as to resemble the letter S; their substance is membranaceous, and they are composed of three coats: the first, a common one, from the peritonæum; the second, a thin muscular one; and the third, a nervous one, covered with a lubricous humour; and in this there are sometimes discovered glands. The blood vessels and nerves come from the adjacent parts.

The use of the ureters is to receive the urine secreted in the kidneys from the pelvis, and to carry it to the urinary bladder. When these are obstructed, a suppression of urine is the consequence; for there is no other way for the urine to get into the bladder but through them. They are often found of an unnatural size, owing to stones concremented from among the urine.

URETHRA, *ουρηθρα*, in anatomy, a membranaceous tube or canal, of a cylindric figure, arising from the neck of the bladder, and continued to the pudendum, serving to discharge and carry off the urine and semen.

The length of the urethra is very different in both sexes. In man it is twelve or thirteen inches, from the neck of the bladder to the extremity of the glans. It is situated in a kind of narrow furrow, formed between the corpora cavernosa, in the bottom or lower part of the penis. It does not run perfectly straight, but is bent in a very singular manner. Its cavity is as large as that of a goose quill.

It is composed of two robust membranes, an exterior and interior; their substance is thin and tough, and between them there is a spongy or cavernous matter, in which some authors pretend to have discovered glands, but this is uncertain.

The bulb of the urethra is that part of it next to the prostate; it is much thicker than the rest of the tube, and is about an inch long, and in some measure resembles a walnut. It is of a thick and spongy texture.

The interior surface of the urethra is full of roundish and oblong foraminulae and furrows, out of which there may often be pressed a thick viscous fluid, the use of which is to lubricate the urethra, and to defend it from the acrimony of the urine. See **PENIS**, &c.

The urethra or urinary passage in women, usually called *meatus urinarius*, is situated straight under the clitoris, and shews itself by a little eminence. Its length is about two fingers breadth; its diameter is greater than that in man, but somewhat narrower at the end than elsewhere. It is capable of great dilatation. There are in it certain little ducts, which convey to its inner surface a mucous humour, for lubricating and defending it from the acrimony of the urine, like those in man; but their origin is uncertain.

URIM and **THUMMIM**, among the ancient Hebrews, a certain oracular manner of consulting God, which was done by the high-priest dressed in his robes, and having on his pectoral, or breast-plate.

Various have been the sentiments of commentators concerning the urim and thummim. Josephus and several others maintain, that it meant the precious stones set in the high-priest's breast-plate, which, by some extraordinary lustre, made known the will of God to those who consulted him.

Spencer believes, that the urim and thummim were two little golden figures shut up in the pectoral, as in a purse, which gave responses with an articulate voice. In short, there are as many opinions concerning the urim and thummim, as there are particular authors that wrote about them.

The safest opinion, according to Broughton, seems to be, that the words *urim* and *thummim* signify some divine virtue and power, annexed to the breast-plate of the high-priest, by which an oracular answer was obtained from God when he was consulted by the high-priest; and that this was called *urim* and *thummim*, to express the clearness and perfection which these oracular answers always carried with them; for *urim* signifies light, and *thummim*, perfection; these answers not being imperfect and ambiguous, like the heathen oracles, but clear and evident.

The use made of the *urim* and *thummim* was to consult God, in difficult cases, relating to the whole state of Israel; and sometimes in cases relating to the king, the sanhedrim, the general of the army, or some other great personage.

URINAL, in medicine, a vessel fit to receive and hold urine, and used accordingly for the convenience of sick persons.

It is usually of glass, and crooked; and sometimes it is filled with milk to assuage the pain of the gravel.

URINAL, in chemistry, is an oblong glass vessel, closed for making solutions, and so called from its resemblance to the glasses in which urine is set to settle for the inspection of the physician. See the preceding article.

URINARIA FISTULA, the urinary passage, or urethra. See **URETHRA**.

URINE, *Urina*, a serous and saline fluid, of a citron colour, separated from the blood, and carried by the emulgent arteries to the kidneys, from whence it descends to the bladder by the ureters, and is, from time to time, emitted thence by the canal of the urethra.

The urine is therefore the serosity of the blood, but not pure, for it is loaded with saline, sulphureous, and terrestrial particles, of which it is the menstruum and the vehicle. The sides of the bladder are guarded by a mucilaginous fluid, excreted by the glands which are between its coats, by which means the urinous salts make the less impression upon it. This fluid forms the glair, which falls to the bottom of the vessel when a person is afflicted with the stone.

It is observable, that there are three sorts of substances differently placed in the urine, viz. the *nubecula*, the *encorema*, and the *hypostasis*. The *nubecula* is a sort of pellicle which swims on the top of the urine, and consists of the saline and fibrous particles of the blood mixed with the serosity. When it is exposed to the fire, it changes to a crustaceous substance. The *encorema*, or suspension, is a white, light, spongy matter which swims in the middle of the urine, consisting of particles of a different nature. The *hypostasis*, or sediment, is a saline, sulphureous, and terrestrial matter, which precipitates to the bottom of the urine.

The urine of four-footed beasts is troubled and muddy, that of men is more clear and limpid. In infants it is more pale and thick than that of middle aged persons. In the very old it is more clear, thin, and has not so much colour. In hot, bilious constitutions, it is more of a saffron colour: in the cold and pituitous, pale. Wine-drinkers have it of a higher colour, and more thick: in those that use much exercise it is little and red: in the idle it is pale, with a large sediment. After meals it is copious, insipid, light, raw, and without smell: after long fasting, it is of a higher colour, acrid, and little. Those that sweat much make little water, which is more muddy and yellow. Diseases cause a remarkable change in the urine. Light, thin, watery urine, shews the person to be afflicted with internal spasms, the hysteric passion, the hypochondriac pains, the cardialgia, the stone or gravel, or convulsive colic. In diseases of the head, such as the vertigo, phrensy, madness, melancholy, and epilepsy, the urine is always thin and light. It is likewise the same in the more grievous afflictions of the nerves from poison or worms. This state of the urine not only happens in the fits, but some days before and after.

When the urine is thin, aqueous, and always white, it presages danger in obstinate diseases: if it is copious in the state of fevers, and before the crisis, it portends a

phrensy. In internal inflammations it is always dangerous, the more copious the worse. After a dysentery, a spotted fever, or the small-pox, this kind of urine is common. In a cachexy, leucophlegmatia, enormous bleedings in the beginning of an anasarca, in the green-sickness, in a suppression of the menses, the urine is crude, turbid, pale, greenish, or of a light citron-colour, and copious. In all preternatural febrile heats, the urine is yellow or red, and in small quantities: such kind of urine as is more or less red, or thin and light, or thick and heavy, is usually in intermitting and continual fevers. In the fit, that is, in its exacerbation or state, the urine is thin, clear, and without sediment. In an ardent and bilious fever, the urine is generally pellucid, but of a flame-colour. In intermittents after the fit, and on the well day, it is thick, and deposits a sediment. If this happens in continual fevers after the crisis, it shews the fever to be ended. If the sediment is of a rosy or purple-colour, it shews the blood is in fault, as is evident in continual fevers. When it is intensely yellow, it discovers that the bile is in fault. When it is brown or black, there is plenty of black bile, as in a scorbutic or miliary fever, and in quartans of a dangerous nature. When it is very plentiful, and full of viscid and crude humours, in replete, obese, and spongy bodies, it shews the obstinacy of an intermitting fever.

As it is a good sign when the urine is thick and deposits a sediment, in fevers; so, on the contrary, if there is no sediment in intermitting fevers, but the urine continues clear, and lets fall no sediment in the cold fit, it is a very bad sign. If, after the fit, it has no sediment, but is pellucid, it is a very bad omen. In all inflammatory fevers, if the urine is clear and of a purple colour, or brown, and of a deep colour, frothy and without sediment, it is a bad sign. Likewise, it is always observed, that in a continual fever, if the urine is turbid, and does not grow clear either by the fire or rest, nor deposits a sediment, it is a very dangerous presage; it is likewise very bad, when in continual fevers, it is thick on the first days, and in the remainder, especially the critical days, it is thin and without sediment. In the decline of catarrhal fevers, and in the small-pox and measles, if the urine was clear and aqueous, but is now thick and high-coloured, with a sediment, it is a certain sign that the disease remits.

In consumptions, and all other violent and chronical diseases, if the urine is thick, high-coloured, and a dark red, with a copious sediment, and a fatness swims upon the urine, and adheres to the sides of the urinal, the body at the same time wasting away, it is a sign of a slow hectic fever, which is generally fatal. The like danger is threatened when in dropical persons the urine is like that of hectic, for its scarcity is a sign that the lymph is extravasated into some cavity or porous substance; and if the colour is of a deep red, with a gross sediment, it shews the intestine motion and heat dissolves the blood, that the liver is obstructed; whence a bilious *fordes* is separated therefrom.

In chronical diseases, without a fever, when the urine is thick, high-coloured, and of a reddish brown, as well as heavy, as in the confirmed scurvy, gout, scorbutic palsy, and in extreme old age, as also in a nephritic passion, when the pains cease, as well as in the yellow and black jaundice, it shews a plenty of saline and sulphureous excrementitious parts, wherewith the blood and humours abound, and are not duly secreted therefrom, by reason of an obstruction of the liver. Willis has observed, that patients dying of the scurvy have had their livers almost without blood, and like a cow's udder. In some the gall-bladder was either empty or full of stones, or very bitter filth.

When the urine is thick, of a deep colour, and dyes linen yellow, it is a sign that the bile is obstructed, or the duct constricted with a spasm, whence the passage of the bile into the duodenum is hindered: whence it regurgitates by the lymphatic vessels into the blood and lymph, and produces a jaundice, which proceeds from an impeded secretion of the bile in the liver.

Sometimes the urine is imbued with an oily matter, and is made without noise, there are various colours on the

the surface, chiefly bluish, and it adheres so strongly to the sides of the urinal, that it cannot be washed off with a lixivious liquor. This is a sign of the colliquation of the fat: it shews a consumption, an atrophy, and an hectic. Sometimes it is observable in fevers, and the oleous matter is more plentiful in proportion to the fatness of the body.

When the urine abounds too much with a tartareous matter, which is known by its adhering to the sides of the chamber-pot, it is a sign of a disposition to the gravel and stone. When there is a small sand in the urine, it shews those disorders to be actually present. Sometimes shining yellow crystals are seen on the sides of the pot, which is a sign of arthritic or rheumatic pains. When the urine is bloody or whitish, from a mixture of pus loaded with a glutinous, thick, tenacious matter, of a bad smell, which sinks to the bottom, and does not dissolve by the agitation of the vessel, it is a certain sign of an ulcer in the kidneys or bladder. Sometimes, in the stone and ulcer of the bladder, it is like the white of an egg, and so tenacious that it will not divide, but fall from the vessel at once.

In a chronical and malignant gonorrhœa, not only the prostatae, but often the bladder, is ulcerated; whence a thick and turbid urine, with a copious sediment, which when thrown on the fire, has a most foetid smell. Likewise, in the stone in the bladder, this, or its sphincter, is so eroded, that the urine is thick and branny, with small caruncles and filaments, which the vulgar take for worms. In the strangury, there is a frequent stimulus to make water, which is little and muddy, sharp and salt, with filaments; and then there is some spasmodic disorder affects the sphincter. If blood is mixed with the urine, like the washings of flesh or red-wine, but falls to the bottom, of a purple colour, it proceeds from the kidneys; but if it be of a brownish black, it comes from the veins of the bladder.

Incontinence of URINE. This is a term used by medical writers to express an involuntary excretion of this liquor, whether it be incessantly, or in larger quantities at different intervals. This is of two kinds: in the one it is only in the night, in the time of sleep; and this arises merely from carelessness, and a bad habit: in the other, it depends on a paralytic affection of the sphincter of the bladder: and in this case it drops away continually from the patient; and this is therefore called by some a stillicidium. Authors also divide an incontinence of urine into the idiopathic and symptomatic: the idiopathic is a disease in itself, and depends upon the preceding causes; the symptomatic happens to different persons on different occasions, as a symptom of other complaints. It is common to dying persons; it is also very frequent to women who are big with child, and sometimes happens from violent sneezing, coughing, or laughing. The voiding of the urine involuntarily, and in the sleep, in infants, is not to be accounted a disease; but when this custom continues with them as they grow up, from idleness, or ill habit, it is at length to be considered as a disease, as they are by no means able to help it. Women who have suffered much in childbirth are often subject to an incontinence of urine afterwards, especially persons who have had their first child at an advanced age. People in years, who are subject to paralytic complaints, are also often afflicted with this troublesome complaint; and many who have been cut for the stone by persons not sufficiently skilled in the operation. Persons subject to the piles also sometimes fall into it, from the suppressions of their usual discharges, and sometimes from the tumours becoming fistulous, and reaching to the neck of the bladder. Imposthumes of the bladder will also occasion it, and violent external injuries.

An incontinence of urine, which happens only in the night, and is merely caused by a bad habit, and not of long standing, usually admits of a cure; but the stillicidia of urine, from paralytic disorders of the sphincter of the bladder, are very rarely cured, especially when they have been fixed some time upon the person. The involuntary voiding the urine in the night, in children, is to be cured, in a great measure, with punishment for-

the neglect, and by denying them much liquids after dinner time; by a proper diet; the avoiding all diuretics, and the making water immediately before going to bed; and when it has gone so far, that the tone of the parts is injured, the usual strengthening medicines are the proper method of curing; in this case, mastic, amber, nutmeg, and cinnabar, are found to be of great service, and pills or powders compounded of them, are an excellent general remedy to be given in small doses, two or three times a day. Externally, it is very proper to use by way of fomentation, decoctions of rosemary, sage, serpyllum, marjoram, and the like warm herbs in red wine. When the disease is occasioned by an imposthume or ulcer in the neck of the bladder, balsamics are to be given, as mastic, gum-juniper, and hoiled turpentine; but when it is owing to injuries received in child-birth, the manual operation of the surgeon is usually to be preferred to all internal medicines.

Difficulty, or Suppression, of URINE.—When the urine of children is suppressed by viscid humours which obstruct the kidneys, or from the relaxed tone of the bladder, or from spasmodic constrictions, producing pains, convulsions, and other disorders, you may give them half a scruple of some neutral salt, such as tartar vitriolate, arcanum duplicatum, and the like; or the same quantity of the seeds, Ray says the flowers, of muscus clavellatus, lycopodium, or club-moss, in parsley water; it being diuretic and antispasmodic. The pubes may likewise be anointed with oil of juniper mixed with oil of amber and aniseed; and then a cataplasm of roasted onions may be laid on hot. These things are likewise good when there is small stones, which they expel. But if these fail, and the symptoms are urgent, a catheter must be introduced into the bladder; which is much easier in girls than boys.

For the diabetes, or that disease wherein the urine comes away crude, exceeding the quantity of the liquids drank, see the article DIABETES.

URINE, in agriculture, is of excellent use as a manure.

The experienced in agriculture and gardening, prefer urine for land, trees, &c. before dung, as penetrating better to the roots; and removing divers infirmities of plants.

The decay of the ancient Kentish pippins, is a thing much complained of; and Mr. Mortimer observes, they will be quite lost, unless some persons set themselves to the ancient way of culture; which, as all ancient graziers and gardeners know, was by washing the mossy, worm-eaten, cankered, and unsound trees, two or three times in the month of March, with the urine of oxen, &c. gathered in earthen vessels, placed under the planks of the stalls wherein they were fatted.

In Holland, and in divers other parts, they preserve the urine of their beasts, &c. with as much care as their dung. Mr. Hartlib, Sir Hugh Plat, Mr. Mortimer, &c. make a common complaint, that so great an improver of land, and so remarkable a strengthener of manure, should be so much disregarded among us.

URINOUS SALTS, are the same with what we otherwise call alkali salts, or alcalies.

URN, *Urna*, a kind of vase, of a roundish form, but biggest in the middle, like the common pitchers, now seldom used but in the way of ornament over chimney-pieces, in buffets, &c. The great use of urns among the ancients was to preserve the ashes of the dead after they were burnt; for which reason they were called cineraria, and urnæ cinerariæ, and were placed sometimes under the tombstone whereon the epitaph was cut, and sometimes in vaults in their own houses. Urns were also used at their sacrifices to put liquid things in.

URN was also a Roman measure for things liquid. See MEASURE.

UROCRITERIUM, casting of water; or giving judgment on diseases by the sight of urine. See URINE.

URSA, the Bear, in astronomy, a name common to two constellations of the northern hemisphere, near the pole, distinguished by major and minor. The ursa major, or the great bear, according to Ptolemy's catalogue, consists of thirty-five stars: according to Tycho's of fifty-

fifty-six; but in the Britannic catalogue we have two hundred and fifteen.

The ursa minor, or little bear, called also Charles's wain; and by the Greeks cynosura; by its neighbourhood to the north pole, gives the denomination *αρκτὺς*, bear, thereto. Ptolemy and Tycho make it to consist of eight stars, but Flamsteed of fourteen.

URSULINES, in church history, an order of nuns, founded originally by St. Angela of Brescia, in the year 1537, and so called from St. Ursula, to whom they were dedicated. They observe the rules of St. Augustine, and are chiefly noted for taking on them the education and instruction of young maids; their monasteries are a kind of schools where young ladies of the best families receive their education. The habit of these religious is a gown of black serge, or other stuff, tied about with a girdle of black leather. The Ursulines are spread chiefly over France and Italy; and their different observances in the several monasteries make them, in truth, so many distinct religious orders.

URTICA, nettle, in botany, a genus of plants, the flower of which is of the apetalous kind, being composed only of a number of stamina placed in a cup. These are barren, and the seeds grow on other plants of the same species, which have no flowers, and are contained either in round globules, or bivalve capsules, or in long tufts.

The roots of the common nettle are much recommended in medicine; they are powerful diuretics, and are said to have great virtues against the stone and gravel. They cleanse the blood, and are said to be of great service in hæmorrhages of all kinds, particularly in spittings of blood, and overflowings of the menses. Authors add to this, that they are specifics by way of antidote against the poison of henbane and hemlock; but this we are not so well assured of. The young shoots of the plant are eaten in the spring, as good against scorbutic complaints. See NETTLE.

URTICA Marina, in zoology, the name of a remarkable genus of fishes, so called from their affecting the skin, on touching them, with a painful sensation like that of stinging of nettles. These are an animal of the lowest class, and have by many been reckoned among those creatures called zoophytes, or plant animals, as supposed to partake of the nature of vegetables and of animals. Some of the species of this fish are found loose upon the smooth shores, and some fixed to the rocks which are always covered with water. M. Reaumur observes also, that many of the species have no property of stinging, or causing any painful sensation of the flesh.

USANCE, *Ufo*, in commerce, is a determinate time fixed for the payment of bills of exchange, reckoned either from the day of the bills being accepted, or from the day of their date; and thus called, because regulated by the usage and custom of the places whereon they are drawn.

Bills of exchange are drawn at one or more usances, either from sight or from date. The term is longer or shorter, according to the different countries. Usance from London to any part of France, is thirty days; this being declared to be a month, in regard to the exchanges in this kingdom, whether the month has more or fewer in it. Usance from London to Hamburgh, Amsterdam, Rotterdam, Middleburgh, Antwerp, Brabant, Zealand, and Flanders, and from these places to London, is one calendar month after the date of the bill. Usance from London to Spain and Portugal, and from these places to London, is two calendar months after date. Usance from London to Genoa, Leghorn, Milan, Venice, and Rome, and from these places to London, is three months. See EXCHANGE.

Usance of Amsterdam upon Italy, Spain, and Portugal, is two months: upon France, Flanders, Brabant, Geneva, and upon any place in the seven United Provinces, is one month. Upon Francfort, Nuremburgh, Vienna, Augsburgh, Cologne, Leipzig, and other places of Germany, as also upon Hamburgh and Breslaw, is fourteen days after sight: two usances twenty-eight, and half usance seven.

Usance from Dantzic, Coningsberg, and Riga, upon Amsterdam, is at one month after sight; though it is common to draw from the first at forty days date, and from the others at forty one, but oftener at ten and eleven. And from Amsterdam on the said places at a month's date, without mentioning usance; though sometimes at forty and forty-one days; and sometimes on Breslaw at six weeks date. Most nations have generally agreed to allow the acceptor of a bill some small time for payment beyond that mentioned in the bill, termed days of grace or respite; but they generally disagree in the number and commencement of them.

USE, in law, the profit or benefit of lands and tenements; or a trust and confidence reposed in a person for the holding of lands, &c. that he to whose use the trust is made shall receive the profits.

Uses may be limited to a person and the wife he shall marry; and if the parties to a deed agree, and declare, that one of them shall make a feoffment, or levy a fine, to the use and intent that he shall hold the lands for his life; and after his decease another in tail, and afterwards a third in fee simple, &c. the estate settles according to the uses in the deed.

The conveyances to uses are said to be of three sorts, viz. a covenant to stand seized; a feoffment, fine or recovery to uses; and a bargain and sale; which last a contingent use cannot be supported by, though it may by the two first.

A superstitious use, is where lands or goods are devised to a priest to pray for the souls of the dead, &c. in which case they become forfeited to the king: and where such an use is void, and the king cannot have the land, it shall not revert to the heir at law; but it may be applied to charity.

USES and Customs of the Sea, are certain maxims or rules which form the basis of maritime jurisprudence, by which the policy of navigation and the commerce of the sea are regulated.

The uses and customs consist of three kinds of regulations: the first called the laws or judgments of Oleron; the second, regulations made by the merchants of Wisbuy, a city in the island of Gothland, in the Baltic, antiently much famed for commerce; and the third, a set of regulations made at Lubec, by the deputies of the Hanse towns.

USHER, an officer, or servant, who has the care and direction of the door of a court, hall, chamber, or the like.

In the king's household there are two gentlemen ushers of the privy-chamber, appointed to attend the door, and give entrance to persons that have admittance thither; four gentlemen-ushers, waiters; and eight gentlemen-ushers, quarter-waiters in ordinary.

USHER, also signifies an officer of the court of Exchequer, of which there are four who attend the barons and chief officers of that court at Westminster, as also juries, sheriffs, &c. at the pleasure of the court. There is also an usher of the court of Chancery.

USHER of the Black-Rod, the eldest of the gentlemen-ushers, daily waiters at court, whose duty is to bear the rod before the king at the feast of St. George, and other solemnities; he has also the keeping of the chapter-house door, when a chapter of the order of the garter is sitting; and, in time of parliament, attends the house of peers, and takes delinquents into custody. He wears a gold badge, embellished with the ensigns of the order of the garter.

USNEA, in botany, a genus of mosses, wholly destitute of leaves, and composed only of long slender filaments, or stalks, which are usually solid, rigid, and of a cylindric figure. The whole plants are fixed in the manner of mistletoe to the barks of trees.

USQUEBAUGH, a strong compound liquor, chiefly taken by way of dram.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of brandy, or other spirits, put a pound of Spanish-liquorice, half a pound of raisins of the Sun, four ounces of currants, and three of sliced dates; the

tops of baum, mint, savory, thyme, and the tops or the flowers of rosemary, of each two ounces; cinnamon and mace; well bruised, nutmegs, anniseeds, and coriander-seeds, bruised likewise, of each four ounces; of citron, or lemon and orange-peel, scraped, of each an ounce; let all these infuse forty-eight hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it is to be put an equal quantity of neat white port, and a gallon of canary; after which it is to be sweetened with a sufficient quantity of double-refined sugar.

USTION, in pharmacy, the preparing of certain substances by burning them.

USTULATION, *Ustulatio*, a word used by pharmaceutical writers to express the roasting or torrefying of humid or moist substances over a gentle fire, so as to render them fit for powdering. The same word is also used by some for what we call burning of wine.

USUCAPTION, *Usucaptio*, in the civil law, is an acquisition of the property of a thing, by a possession and enjoyment thereof for a certain term of years prescribed by law.

USUFRUIT, *Usus Fructus*, in the civil law, the use or enjoyment of any lands or tenements; or the right of receiving the fruits and profits of an inheritance, or other thing, without a power of alienating or changing the property thereof.

USURER, a person charged with a habit or act of usury. See the article **USURY**.

USURIOUS CONTRACT, is any bargain or contract, whereby a man is obliged to pay more interest for money than the statute allows.

USURPATION, in law, is an injurious using or enjoyment of a thing for continuance of time, that belongs of right to another.

USURY, *Usura*, in the general, denotes a gain or profit, which a person makes of his money, by lending the same; or it is an increase of the principal, exacted for the loan thereof; or the price a borrower gives for the use of a sum credited to him by the lender, called also interest; and in some ancient statutes, dry-exchange.

The word usury is generally taken in an evil sense, viz. for an unlawful profit which a person makes of his money; in which sense it is, that usury is forbidden by the civil and ecclesiastical, and even by the law of nature.

By stat. 12 Ann. c. 16. which is called, The Statute against excessive Usury, it is ordained, that no person shall take for the loan of any money, or other thing, above the value of five pounds for the forbearance of one hundred pounds for a year; and so in proportion for a greater or lesser sum: and it is declared, that all bonds, contracts, and assurances, made for payment of any principal sum to be lent on usury, above that rate, shall be void; and that whosoever shall take, accept, or receive, by way of corrupt bargain, loan, &c. a greater interest than that last above-mentioned, shall forfeit treble the value of the money lent; and also, that scriveners, solicitors, and drivers of bargains, shall not take or receive above five shillings for the procuring the loan of one hundred pounds for one year, on pain of forfeiting twenty pounds, &c.

There can be no usury without a loan, between which and a bargain the court has distinguished: and though a person is to pay double the sum borrowed, &c. by way of penalty, for the non-payment of the principal debt, it is not usury; so it also is in respect to the grant of an annuity for lives, or on condition, where it exceeds the usual interest, and the proportion attending contracts of this kind. Even if one secures a large interest and principal, and it is at the will of the party who is to pay; or where it happens that both the principal money and extraordinary interest are in hazard, or that a person may have less than his principal; as when a bond is made to pay money upon the return of a ship from sea, &c. either of these cases are not held to be usury.

In an action brought for usury, the statute made against it must be pleaded; and in pleading an usurious

contract, as a bar to an action, the whole matter is to be set forth specially, because it lies within the parties own privacy; yet on an information on the statute for making such contract, it is sufficient to mention the corrupt bargain generally; because matters of this kind are supposed to be privily transacted; and such information may be brought by a stranger. 1 Hawk. P. C. 248.

Likewise upon an information on the statute against usury, he that borrows the money may be a witness, after he has paid the same.

UT, a Latin term, literally signifying *as*, much used in stating of ratios and proportions.

UT, in music, the first of the musical notes, which, with the rest, was taken out of the hymn of St. John Baptist, *Ut queant laxis*, &c. See the articles **SCALE**, **MUSIC**, &c.

UTENSIL, *Utenfile*, a little domestic moveable, belonging principally to a kitchen: such are pots, pans, &c.

Utensils are more particularly used in war, for the moveables which the host is obliged to furnish the soldiers quartered with him; which are, a bed with bed clothes, a pot, and a spoon.

UTERINE, *Uterinus*, something belonging to the uterus, or womb of a woman.

Furor UTERINUS, in medicine, denotes a kind of madness, attended by lascivious speeches and gestures, and an invincible inclination to venery. See **FUROR**.

UTERUS, the womb, in anatomy, a hollow body, called also the matrix, of a form approaching to that of a pear, situated between the bladder and the rectum, and destined to the office of generation, for the containing the foetus. It is connected in the anterior part with the vagina, and at its lateral part by the ligaments, lata and rotunda, being loose in its hinder part.

In women not with child, the length of the uterus is about three inches; its breadth, in the upper part, being about two inches, and in the lower part one. Its thickness is about an inch and an half: in virgins, indeed, it is much smaller than this; but in women with child it is of a different size, according to the different time of gestation.

Anatomists divide it into two parts; the upper and broader part they call the fundus uteri, and the lower they call the cervix, into which it is that the vagina opens. See **VAGINA**.

The orifice, or, as it is otherwise called, the internal mouth of the womb, opens into the vagina, in form of the glans penis in men: it is very small in virgins, but in women who have had children, or who are with child, it is larger; and in the last it is always closed up with a glutinous humour: in the time of delivery, it in a wonderful manner expands itself, so as to give passage to the child. See **DELIVERY**.

The substance of the womb is musculous, being composed of a various plexus of fleshy fibres with a great number of vessels between. In women not with child, it is compact and firm; in those with child, it is spongy and sinuous, and is capable of wonderful dilatation, without any diminution of its thickness. It is covered externally with a membrane from the peritonæum, and internally, its cavity is lined with a porous and nervous membrane: this cavity is very small in virgins; and in women with child, the inner membrane almost entirely disappears.

The blood-vessels of the uterus are tortuous, and make a thousand anastomoses with one another: they open by a number of little mouths into the uterus and vagina, and are the sources of the menstrual discharge in women. See **MENSES**.

The arteries are of three kinds, viz. spermatics from the aorta; very large ones from the hypogastrics; and others from the hæmorrhoidal arteries. The veins of the uterus are also of three kinds, and of the same denominations: they have valves, and are greatly larger than the arteries, especially in women with child. The nerves of the womb are from the intercostals, and those of

of the os sacrum. The lymphatics have long since been discovered in brutes; but Morgagni has of late years found them also in human subjects.

UTILE, a Latin term, signifying profitable or useful; in which sense it is sometimes used by English writers.

UVEA, in anatomy, the third or outermost coat of the eye. See EYE.

VULCANO, or VOLCANO, in natural history, a burning mountain, or one that vomits forth fire, flame, ashes, cinders, &c. See the article MOUNTAIN.

As to the cause of vulcanos, it is found by experience, that there are several inflammable bodies, which, being mixed together in due proportion, will kindle into flame by fermentation alone, without the help of any fiery particles. Thus M. Lemery having covered up in the earth about fifty pounds of a mixture, composed of equal parts of sulphur and filings of iron, tempered with water; after eight or nine hours time, the earth, where it lay, vomited up flames. From this experiment we see the true cause of the fire of *Ætna*, *Vesuvius*, and other burning mountains, which probably are made up of sulphur and some other matter proper to ferment with it, and take fire.

VULGATE, a very ancient Latin translation of the Bible, and the only one the church of Rome acknowledges to be authentic.

The vulgate of the Old Testament was translated, almost word for word, from the Greek of the Septuagint: the author of it is not known, or so much as guessed at. It was a long time known by the name of the Italic Version, as being of great antiquity in the Latin church. It was commonly in use, before St. Jerom made a new one from the Hebrew. St. Austin preferred this vulgate before all the other Latin versions, as rendering the words and sense of the sacred text more closely and justly than any of the rest. It has been since corrected from the emendations of St. Jerom; and it is this mixture of the ancient Italic version with the corrections of St. Jerom, that is now called the vulgate, and which the council of Trent has declared to be authentic.

The vulgate of the New Testament is, by the Romanists, generally preferred to the common Greek text. The priests read no other at the altar; the preachers quote no other in the pulpit, nor the divines in the schools. F. Bouhours spent the last years of his life in giving a French translation of the New Testament from the vulgate. Yet that judicious critic owns, that, in some few passages, the Greek appears more clear and in-

telligible than the Latin. The editors of the Oxford Greek Testament, 1675, declare, there is no version in any language to be compared with the vulgate. See the article BIBLE.

VULNERARY, in medicine, an epithet given to remedies proper for the cure of wounds and ulcers.

All medicines of this intention are supposed both to cleanse and heal; that is, incarnate, or fill up with new flesh, all ulcerations and foulnesses. Under this head are ranged all such balsamics as are not only softening and adhesive, but also, by a peculiar activity, joined with a suitable configuration of parts, are apt to abrade and carry along with them what particles they hold on in their passage.

VULPES, the fox. See the article Fox.

VULTURE, a genus of birds, with four toes on each foot, three of which are placed forwards; the neck is long, and almost bare of feathers; the legs are covered with feathers down to the feet, or nearly so; and under the throat there is a space covered with hairs instead of feathers; the head also in many species, is naked, and has at the most only a downy matter on it, instead of feathers; and the under part of the wings is downy.

VULVA, in anatomy, a name given as well to the uterus, or womb, as to the cunnus or pudendum muliebre. See UTERUS and PUDENDUM.

UVULA, in anatomy, a round, soft, spongy body, like the end of a child's finger, suspended from the palate, near the foramina of the nostrils, perpendicularly over the glottis. Its use is to break the force of the cold air, and prevent its entering too precipitately into the lungs. It is formed of a duplicature of a membrane of the palate; and is called, by some authors, columella, and by others gurgulio.

It is moved by two pair of muscles, and suspended by as many ligaments.

UVULARIA, in botany, a genus of plants, whose flower consists of six oblong, erect, lanceolated petals, with an oblong nectarium cut into the base of each petal; the stamina are six very short filaments, topped with long erect antheræ; the fruit is an ovato-oblong trilocular capsule, containing many roundish compressed seeds.

UXOR, among chemists, signifies the mercury of metals. See MERCURY and METAL.

UXORIUM, in antiquity, a fine or forfeit paid by the Romans, for not marrying.

UZIFIR, UZUFAR, or UZIFUR, in chemistry, a name which some authors give to cinnabar. See CINNABAR.

W.

W A G

W, The twenty-first letter of our alphabet, and composed, as its name implies, of two V's. It was not in use among the Hebrews, Greeks, or Romans, but chiefly peculiar to the northern nations, the Teutones, Saxons, Britons, &c. but still it is not used by the French, Italians, Spaniards, or Portuguese, except in proper names, and other terms borrowed from languages in which it is originally used, and even then it is sounded like the single V.

This letter is of an ambiguous nature, being a consonant at the beginning of words, and a vowel at the end. It may stand before all the vowels except *u*, as *water*, *wedge*, *winter*, *wonder*. It may also follow the vowels *a*, *e*, *o*, and unites with them into a kind of double vowel, or diphthong, as in *saw*, *few*, *cow*, &c. It also goes before *r*, and follows *s*, and *th*, as in *wrath*, *swear*, *thwart*: it goes before *h* also, though in reality it is sounded after it, as in *when*, *what*, &c. In some words it is obscure, as in *shadow*, *widow*, &c.

WADD, or **WADDING**, is a stopple of paper, hay, straw, or the like, forced into a gun upon the powder, to keep it close in the chamber; or to put up close to the shot, to keep it from rolling out.

WAST. To waft a ship, is to convoy her safe, as men of war do merchant-ships. To make a waft, is to hang out some coat, sea-gown, or the like, on the main shrouds of the ship, as a signal for people to come aboard, and signifying that the ship is in great distress.

WAFERS, or **SEALING WAFERS**, are made thus: Take very fine flour, mix it with glair of eggs, in glass, and a little yeast; mingle the materials; beat them well together, spread the batter, being made thin with gum-water, on even tin plates, and dry them in a stove; then cut them out for use.

You may make them of what colour you please, by tinging the paste with Brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, turmeric, or gamboge, &c. for yellow.

WAGE, in law, denotes the giving security for the performance of any thing.

WAGER of Law, is used where an action of debt is brought against a person, upon a simple contract between the parties, without deed or record, and the defendant, in presence of his compurgators, swears in court, that he owes the plaintiff nothing in form and manner as he has declared: and here the reason of waging of law is, because the defendant may have paid to the plaintiff his debt in private, or before witnesses who may be all dead, and therefore the law allows him to wage his law in discharge; and in that case his oath shall be accepted to discharge himself, rather than the law will suffer him to be charged upon the bare allegation of the plaintiff. The method of waging law is this, viz. the defendant

generally brings six compurgators with him into court, and stands at the end of the bar towards the right hand of the chief justice; the secondary asks him whether he will wage his law? whereto if he answers that he will, the judges admonish him to be well advised, telling him the danger of taking a false oath; and if he still persists, then the secondary says, and the defendant, who wages his law, repeats after him, "Hear this, ye justices, that I C. D. do not owe to A. B. the sum of ———, nor any penny thereof, in manner and form as the said A. B. has declared against me: so help me God." After the defendant has thus sworn, and the compurgators given in, upon oath, that they believe he swears true, the plaintiff is for ever barred; it being as much as if a verdict had passed against him.

WAGGON, a vehicle or carriage, of which there are various forms, accommodated to the different uses they are intended for.

The common waggon consists of the shafts or rads, being the two pieces which the hind horse bears up; the welds; the flotes, or cross-pieces which hold the shafts together; the bolster, being that part on which the fore-wheels and the axle-tree turn, in wheeling the waggon across the road; the chest, or body of the waggon, having the staves or rails fixed thereon; the bales, or hoops, which compose the top; the tilt, the place covered with cloth, at the end of the waggon. For the principles on which this carriage is constructed, see the article **WHEEL**.

WAGGON-Master-general, in the military art, is he who has the ordering and marching of the baggage of the army. On a day of march he meets the baggage at the place appointed in the orders, and marshals it according to the rank of the brigade or regiment each waggon belongs to, which is sometimes in one column, sometimes in two; sometimes after the artillery; and sometimes the baggage of each column follows their respective column.

WAGTAIL, in ornithology, the name of two different species of motacilla.

The white or common wagtail is the motacilla with a black breast. This is a very beautiful bird, much about the size of the goldfinch, but the body is longer in proportion, and much better covered with feathers; the head is large and rounded; the eyes are large, and their iris hazel; the beak is strait, slender, moderately long and black; the beak and the eyes are surrounded with a space of white, which is continued in a broad line down almost to the wings; the crown of the head, both sides of the neck, and back are black, the breast and belly are white; the tail is long, and both that and the wings are variegated with black and white.

The other species is the yellow wagtail, or the yellow breasted motacilla, much resembling the former, only

only that the breast and belly are yellow; the sides of the head variegated with some strokes of yellow, and the wings with white.

WALF, or **WAFE**, in law, a term applied to such goods as a thief having feloniously stolen, on his being closely pursued, are waived or left by the felon, which become forfeited to the king, or lord of the manor: and so it also is where a felon has the goods in his custody, and apprehending that pursuit is made, he flies, and leaves them behind him.

Though waif is properly applied to goods that are stolen, yet it may be also said of goods not stolen or taken away, as where a person is pursued with hue-and-cry as a felon, and he flies and leaves his own goods; in this case these shall be forfeited as stolen goods, or what are usually called fugitives goods.

WALF, is also applied to things lost, and estrays, which, no owner appearing, are forfeited to the lord of the manor, after they have been cried and published in the markets.

WAINSCOT, in building, the timber-work that serves to line the walls of a room, being usually made in pannels, and painted, to serve instead of hangings.

It is usual, even in halls, to have wainscot breast high, by reason of the natural moistness of the walls. Some joiners put charcoal behind the pannels, to prevent the sweat of the stone and brick walls from ungluing the joints; others use wool for the same purpose; but the only sure way is to prime over the back-sides of the joints with white-lead, Spanish brown, or linseed-oil.

The wainscotting with Norway oak, according to Neve, the workman finding stuff, is valued at 6 s. or 7 s. per yard square; plain square wainscotting, the workman finding deal, is valued at 3 s. and 3 s. and 6 d. per yard. Ordinary bisection wainscotting, the workman finding deal, is worth 3 s. and 6 d. and 4 s. per yard. Large bisection wainscotting with Dantzic stuff, is valued at 6 s. or 7 s. per yard.

WAIVE, according to the different acceptations of the word, signifies to forsake, but in the law it is especially applied to a woman, who, for any crime, for which a man may be outlawed, is termed waive.

WAIVER, in law, denotes the passing by a thing, or a refusal to accept thereof; and relates sometimes to an estate conveyed to a person, and sometimes to a plea.

It is held, where a particular estate is granted with a remainder over; in that case, he that has it, may not regularly waive it to the damage of him in remainder; tho' where one has the reversion, it is otherwise, for that is not hurt by such waiver.

WAKE of a Ship, is the smooth water astern when she is under sail: this shews the way she has gone in the sea, whereby the mariners judge what way she makes.

If the wake be right astern, they conclude she makes her way forwards; but if the wake be to leeward a point or two, then they conclude she falls to the leeward of her course. When one ship, giving chase to another, is got as far into the wind as she can, and sails directly after her, they say, she has got into her wake.

A ship is said to stay to the weather of her wake, when in her staying, she is so quick, that she does not fall to leeward upon a tack, but that when she is tacked, her wake is to the leeward; and it is a sign she feels her helm very well, and is quick of steerage.

WAKE, is the eve feast of the dedication of churches, which is kept with feasting and rural diversions.

WALE, or **WALES**, in a ship, those outermost timbers in a ship's side, on which the sailors set their feet in climbing up.

They are reckoned from the water, and are called her first, second, and third wale, or bend. See **SHIP**.

WALE-KNOT, a round knot, or knob, made with three strands of a rope, so that it cannot slip, by which the tacks, top-sail sheets, and stoppers, are made fast, as also some other ropes.

WALE REARED, on board a ship, a name the seamen give to a ship, which, after she comes to her bear-

ing, is built straight up: this way of building, though it does not look well, nor is, as the seamen term it, ship-shaped, yet it has this advantage, that a ship is thereby more roomy within board, and becomes thereby a wholesome ship at sea, especially if her bearing be well laid out.

WALES, a principality in the west of England, comprehending twelve counties, bounded by Cheshire, Shropshire, Herefordshire, and Monmouthshire, on the east, and surrounded by the sea called the Irish Channel on the north, west, and south.

WALK, in gardening, an ornamental and useful part of a garden, differing from an alley by being wider.

Walks are either straight or serpentine; the materials of which they are formed are gravel, sand, or grass; but where sand or gravel cannot be procured, they are sometimes laid with powdered coal, sea-coal ashes, and sometimes with powdered brick, but none equals those made with gravel, and in order to the laying those kind of walks, it is very proper to fill the bottom with lime, rubbish, flint stones, coarse gravel or other rocky materials, which will be of service to prevent weeds from growing through the gravel, and to hinder worm-casts; this bottom should be ten inches or a foot thick, over which a coat of fine gravel, mixed with a due proportion of loam, should be laid, to the thickness of ten inches. The common allowance for a gravel walk of five feet breadth is an inch in the crown, so that if a walk be twenty feet wide, it should be four inches higher in the middle than on each side.

When a walk has been evenly laid, trodden down, and raked, it should then be rolled well both in length and width; and in order to make them more firm, it will be necessary to give them three or four water-rollings, that is, they should be rolled when it rains very fast: this will cause the gravel to bind, so that when the walks come to be dry, they will be as hard as terrace.

Gravel walks are not only very necessary near the house, but there should always be one carried quite round the garden, because being soon dry after rain, they are proper for walking on in all the seasons; but then these should be but few, and those adjoining to the house ought to be large in proportion to the size of the house and garden: the principal of these walks should be elevated, and carried parallel with the house, so as to form a terrace; this should extend itself each way in proportion to the width of the garden, so that from this there may be a communication with the side walks, whereby there may be dry walking all round the garden.

Sand walks are also frequently made in gardens; these are less expensive in the making, and also in keeping in order than those of gravel; for as the greatest part of the walks which are made in modern gardens twist about in an irregular serpentine manner, it would be very difficult to keep them handsome if they were laid with gravel, especially where they are shaded by trees; for the dripping of the water from their branches in hard rains, is apt to wash the gravel in holes, and render the walks very unsightly; therefore those walks which go through woods and plantations are much better if laid with sand, which will be dry and wholesome, and whenever they appear mossy, or any weeds begin to grow on them, if they are scuffled over with a Dutch hoe in dry weather, and raked smooth, it will destroy the moss and weeds, and make the walks appear as fresh and handsome as when first laid.

The breadth of these walks should be proportioned to the size of the ground, which, in a large extent, may be twelve or fourteen feet wide, but in small gardens five or six will be sufficient.

The ground being traced out in the manner as the walks are designed, the earth should be taken out of the walk, and laid in the quarters; the depth of this must be proportioned to the nature of the soil, for where the ground is dry, the walks need not be elevated above the quarters, so the earth may be taken out four or five inches deep in such places; but where the ground is wet, the bottom of the walks need not be more than two inches below the surface, that the walks may rise so high

as to throw off the wet into the quarters, which will render them more dry and healthy to walk on: after the earth is taken out, the bottom of the walks should be laid with rubbish, coarse gravel, &c. to the thickness of five or six inches, and beaten down close, to prevent the worms from working through it; then the sand should be laid upon this about three inches thick, and after treading it down, it should be raked over to level and smooth the surface: the sand that is fitting for this purpose should be such as will bind, otherwise it will be very troublesome to walk on them in dry weather; for if the sand be of a loose nature, it will be moved by strong gales of wind, and in dry weather will slide from under the feet; and if it is too much inclinable to loam, it will also be attended with as ill consequence as that which is too loose, for this will stick to the feet after every rain; so that where sand can be obtained of a middle nature, it should always be preferred.

Grass walks in gardens were formerly held in great esteem, and were looked upon as necessary ornaments to a garden; but of late years they have been much less regarded; for these long narrow slips of grass are far from being pleasing to the eye, and are for the greatest part of the year useless, being generally too damp for persons of tender constitutions to walk on; and whenever they were constantly used, they became bare in the places frequently trodden, so were rendered more unightly; and as the intention of walks in gardens is to have at all seasons a dry communication through them for exercise and recreation, grass walks were very improper, because every shower of rain made them so wet, as not to be fit for use for a considerable time; and the dews rendered them damp to walk on either in the morning or evening, and if they are not kept constantly close mowed, then they become not only unhealthful but troublesome to the feet; besides, whenever the ground is so dry, as that persons may with safety walk upon grass, the lawns and other parts of verdure in gardens are better adapted for use than any of these formal stiff walks, which were so much esteemed in the last age.

WALK, in the manege, is the slowest, and least raised of all a horse's goings. It is performed by the horse's lifting up his two legs on a side, the one after the other, beginning with the hind leg first. Thus, if he leads with the legs of the right side, then the first foot he lifts is the far hind-foot, and in the time he is setting it down, which in a step is always short of the tread of his fore-foot on the same side, he lifts his far fore-foot, and sets it down before his near fore-foot. Again, just as he is setting down his far fore-foot, he lifts up his near hind-foot, and sets it down again just short of his near fore-foot; and just as he is setting it down he lifts his near fore-foot, and sets it down beyond his far fore foot.

WALL, in architecture, the principal part of a building, as serving both to inclose it, and support the roof, floors, &c. See **BUILDING**.

Walls are distinguished into various kinds, from the matter of which they consist, as plastered or mud walls, brick-walls, stone-walls, flint, or boulder walls, and boarded walls. In all which these general rules are to be regarded. 1. That the right angle therein depending is the true cause of all stability, both in artificial and natural position. 2. That the massiest and heaviest materials be the lowest, as fitter to bear than to be borne. 3. That the walls, as they rise, diminish proportionably in thickness, for ease both of weight and expence. 4. That certain courses or ledges, of more strength than the rest, be interlaid, like bones to strengthen the whole fabric. See **HOUSE**.

Brick-walls are the most important and usual amongst us. In these, particular care is to be taken about laying of the bricks; that in summer they be laid as wet, and in winter as dry, as possible, to make them bind the better with the mortar: that in summer, as fast as they are laid, they be covered up, to prevent the mortar, &c. from drying too fast: that in winter they be covered well to protect them from rain, snow, and frost, which are all enemies to mortar: that they be laid joint on joint in the middle of the walls as seldom as may be: but that

good bond be made there as well as on the outside. Care is to be taken that the angles be firmly bound, which are the nerves of the whole edifice. In order to which, in working up the walls of a building, it is not advisable to raise any wall above eight feet high, before the next adjoining wall be wrought up to it, that so good bond may be made in the progress of the work: it may be worth notice, that a wall a brick and a half thick, with the joint, will be in thickness fourteen inches, or very near; whence 150 or 160 bricks will lay a yard square measured upon the face of the building; and to the square of ten feet are usually allowed 1700 or 1800 bricks.

Flint, or boulder walls are much used in some parts of Suffex and Kent, for fence-walls, round courts, gardens, &c. A right and left-handed man fits well for this work, as they have a hod of mortar poured down upon the work, which they part between them, each spreading it towards himself, and so they lay in the flints. The mortar for this work must be very stiff.

WALL, in gardening. — Of all materials for building walls for fruit-trees, brick is the best; it being not only the handsomest, but the warmest and kindest for the ripening of fruit; and affording the best conveniency for nailing, as smaller nails will serve in brick than will in stone walls, where the joints are larger; and if the walls are coped with free-stone, and stone pilasters or columns at proper distances, to separate the trees, and break off the force of the winds, they are very beautiful, and the most profitable walls of any others.

In some parts of England there are walls built both of brick and stone, which are found very commodious. The bricks of some places are not of themselves substantial enough for walls; and therefore some persons, that they might have walls both substantial and wholesome, have built these double, the outside being of stone, and the inside of brick: but there must be great care taken to bind the bricks well in the stone, otherwise they are very apt to separate one from the other, especially when frost comes after much wet.

There have been several trials made of walls built in different forms; some of them having been built semicircular; others in angles of various sizes; and projecting more towards the north, to screen off the cold winds: but there has not as yet been any method which has succeeded near so well as that of making the walls straight and building them upright. Where persons are willing to be at the expence, in the building of their walls substantial, they will find it answer much better than those which are slightly built, not only in duration, but in warmth: therefore a wall two bricks thick, will be found to answer better than one of a brick and a half: and if in building of garden-walls they are grouted with soft mortar, to fill and close all the joints, the walls will be much stronger, and the air will not so easily penetrate, as it does through those which are commonly built.

If the walls are built on arches, and the trees planted at those arched places, the trees will be thereby enabled to extend their roots underneath the wall, and be greatly benefited, and forwarded in their growth.

It has been hitherto an almost unvaried practice, to plant all the finer fruits against walls, without sufficiently inquiring into the motives for so doing. But it should be observed in the first place, that the borders under the walls are seldom made so wide as they ought to be, considering that the trees which are planted there can extend their roots but one way: and secondly, that due care is not taken to adapt the quality of the soil there to the nature of the trees; a precaution which ought to be attended to by those who are curious in their fruit, and which would cost only the trifling expence of bringing in a sufficient depth of proper earth.

The chief reason assigned for planting trees against walls is, the additional heat procured by the reflected rays of the sun, and the warmth communicated to the wall itself by the sun. This, say the advocates for this practice, hastens the ripening of the fruit, and exalts its flavour; besides, that the shelter of the walls protects trees, natives of warmer climates, from our severe north and north-east winds.

To this it may be answered, that it is a constant observation, that all plants brought from a warmer climate to a colder, endeavour to bloom at their usual season, unless they are prevented by cold. The consequence of this is, that if the early part of the spring happens to be warm, the blossoms of such trees swell, and expand themselves: but as we cannot be exempted from frost so soon in the season, these blossoms are nipped in the bud; that is, the first frosty night stops the circulation in them, and they then necessarily die. Nothing shews more incontestibly the stoppages of the circulation in trees, than tapping, for instance, a birch tree, early in the spring: for the warmth, or coldness, of the air at that time may be determined by the greater or less velocity with which the juice flows, or by the greater or less quantity of it, that is discharged, almost as certainly as by a thermometer. In frost, the discharge ceases entirely. It therefore is not at all wonderful, that the circulation is interrupted, by the same cause, in the finer vessels of flowers, and that the death of the flower is the necessary consequence. A very sharp frost, even after the early fruits are set, has the same effect on their yet tender vessels; and the owner is surprised to find his fruit fall off, in a few days after, without any seeming cause; unless recourse be had to I know not what pestilential quality in the east wind, when the same effect would follow, did the frost come from any other quarter. Hence it is evident, that fruit trees would be benefited, rather than hurt, by preventing their too early blossoming.

Some gentlemen endeavour to guard against this accident, by sheltering their trees with skreens, which have a double effect; that of preserving them from the warmth of the sun by day, and that of defending them from the frost by night. But if these trees were planted as standards, where the air might play freely round them, the motion of the sap would be less forward, and the blossoms would consequently be less exposed to the injuries which happen from their coming out too early. They would likewise escape another great inconvenience which attends their standing against walls; namely, the too great inequality of the heat, as increased by the wall, and the coldness of the night, against which the wall affords no shelter, otherwise than as it skreens the trees from the wind.

A farther reason which renders walls the less necessary is, that the fruits planted against them ripen before the sun has acquired its full force in this climate. This is what happens to all our apricots, to most of our nectarines, and to the finest of our peaches: for it is well known, that the month of July is our hottest season, and that the heat of that month will therefore the most perfectly exalt the juices and flavour of fruit.

Walls may indeed be necessary for the later peaches; though even a Catherine peach will ripen on a standard, in a favourable situation.

All the stone fruits are accounted peculiarly proper for walls, and so are many kinds of pears. Some of the finer sorts of these last may indeed do well enough when so planted: but I cannot by any means think the cherry, for example, a proper tree for a wall, because it will not bear the cutting necessary to train it in that manner. The late pears and peaches are, in my opinion, the only fruits really fit for this sort of culture. However, for the sake of those who chuse to continue to extend it to other kinds, we shall observe, that peach trees, and those of nectarines, placed against walls, should be set about twelve feet asunder: apricots should be allowed a breadth of sixteen or eighteen feet; cherries and plums, twenty-five feet; and most sorts of vigorous shooting pears, from thirty to forty, according to the goodness of the soil, and the height of the wall.

The root of the tree taken from the nursery should be placed in a hole dug about five inches from the wall, and its head should be inclined thereto, with the bud turned outwards, to conceal the wounded part of the stock. The hole should then be filled up, so as neither to leave chasms between the roots, nor to press the earth down too hard upon them. Some of the twigs of the young tree should then be fastened to the wall, to prevent the wind's displacing it so as to break the tender fibres of its roots; the

surface of the ground should be covered with mulch, to keep out the frost; and in the following spring, about the beginning or middle of March, according as the season is earlier or later, the head of the tree should be cut down to four or five eyes above the bud, just before it begins to shoot. In this cutting off the head, the gardener, to avoid as much as possible giving any disturbance to the roots, should set his foot down close to the stem of the tree, and take fast hold of the stock, below the bud, with one hand, to keep it steady, whilst, with the other, he slopes off the upper part gently, with a sharp knife, at the intended place, which should always be just above an eye. This should be done in dry weather; for if much rain should fall soon after, and wet get into the wounded part, the tree will be liable to suffer considerable damage: and for the same reason, together with its preventing the closing of the wound, frosty weather should also be cautiously avoided. After the tree has been headed, the earth of the borders should be loosened gently, to render it more fit to admit the fibres of the roots, and if the mulch which was laid on in the autumn be rotten, it may be dug into the border, at some distance from the roots, with all possible care not to disturb or break them. When the dry weather comes on, a few sods pared off from a pasture ground, and laid upon the surface of the border, about the roots of the trees, with the grass downward, will preserve a gentle moisture in the earth, and be less apt to harbour insects, than any sort of dung or litter.

The above is the usual method of transplanting trees from the nursery to a wall. But Mr. Miller is convinced, from experience, that, instead of taking from the nursery stocks (especially of peaches and nectarines) which have then made one year's shoots from the bud, it is better to single out such as were budded the preceding summer, and have not made any shoot; provided the bud be sound and plump, and the bark of the stock well closed at the place of budding; because, when this shall have put forth a shoot five or six inches long, in the following spring after being transplanted, as it will seldom fail to do, that shoot may be stopped by pinching off its top, and thereby be made to produce lateral shoots, which may be trained to the wall, without having any head to cut off, at must be done to those trees which have had one year's growth in the nursery. The benefit of avoiding this operation is particularly great to such trees as are apt to bleed much, and singularly so to the most tender sorts. The stock of the tree transplanted in bud, before it has made any shoots, must indeed be cut down, likewise in the spring, to just above the bud, because this will rarely shoot unless that be done; and the nearer it is cut to the bud, the sooner will the head of the stock be covered by the bud: for there is no occasion to leave on trees which are planted against a wall, a part of the stock, above the bud, to fasten the shoots to, as must be done with those in the nursery; because the shoots may here be immediately and properly secured, by fastening them to the wall: nor is this cutting off the superfluous part of the stock attended with any danger to the bud, if the wound be but covered with a little grafting wax, or clay, to keep out the wet.

No time is lost, but some may be gained, by this practice; as the trees which have shot before their being transplanted must be cut down, and there is a hazard of their shooting again.

In watering of these new planted trees, which should not be done unless the spring prove very dry, nor then often, or in great quantity, the pot should have its nozzle on, so as to let the water out very gently, almost in drops only, as it were; for when it is poured down hastily, it hardens the ground: and if the head of the tree is watered at the same time as its roots, and likewise gently, that refreshing will be of great service to it.

About the middle of May the shoots of these trees, of which there will then often be several six or eight inches long, should be nailed horizontally to the wall. All foreright shoots, and such as are weak, should also then be rubbed off, to strengthen those that are left. But if no more than two shoots have been produced, and those very strong, the tops of these should be nipped off

at that time, and this will make each of them put out two or more shoots, whereby the wall will be the better furnished with branches. It will also be right to continue to refresh them gently with water, from time to time, during the whole summer, if that season should be very dry, lest their roots, having but little hold of the ground the first year after transplanting, should be injured by the drought, so as to retard the growth of the tree.

In the beginning of October, when the trees have done shooting, it will be time to begin to prune them. In doing this, the branches must be shortened in proportion to the strength of the tree; that is, if it be strong, they may be left eight inches long; but if weak, they should be shortened to four or five. The shoots thus cut should then be trained horizontally to the wall, so as to leave the middle of the tree void of branches, for that part will be easily furnished with wood afterwards; whereas, if the shoots are trained perpendicularly to the wall, the strongest will draw away the greatest share of the sap from the roots, run upwards, and leave the side branches so destitute of nourishment, as frequently to occasion their decaying and dying.

In the next summer, when the trees begin to shoot, they should be carefully looked over again; all fore-right or ill placed buds or shoots should be rubbed off, and such as are to remain, for future branches, should be trained up horizontally to the wall, in due order, as they are produced; for this is the principal season in which all fruit trees are best and most effectually modelled to their intended form. Every gentleman who wishes his trees to prosper to the utmost, and to grow with as much beauty as they are susceptible of, should therefore personally look over them at this time, and, with his own hand, rub off their superfluous buds and shoots: for if this elegant and essentially useful part of gardening is left to the hired gardener, it will often be neglected, or slovenly performed. Whosoever omits it, deserves not to have good fruit. This important business should not be deferred till Midsummer, as is the common practice, because numbers of useless shoots, which must afterwards be cut off, will by that time have robbed the other parts of their due nourishment: and besides, it is by stopping some of the stronger shoots (by nipping off their tops) in May, that they are made to put out side shoots, which, being guided to the vacant parts of the wall, furnish every part thereof regularly with proper wood. Care must, however, be taken not to multiply these branches too much, for fear of weakening the tree so as to disable it for producing good fruit; and therefore no shoots should be stopped in the summer, unless there be an absolute necessity for new branches in any particular place. Neither should the branches be laid in too close together against the wall, because the great numbers of their leaves then exclude the air from their shoots, so that these are never duly ripened, and the fruit which is afterwards produced on them cannot, consequently, be so well tasted as that of trees whose shoots receive all the advantages of the sun and air, to bring them to maturity.

In the third year, the branches till then trained horizontally will have acquired such strength, that there will not be much danger in permitting some of their shoots to go in a more perpendicular direction, in order gradually to give the whole tree the form of a fan, which is by much the most beautiful, as well as the best way here, because the wall is thereby most equally filled with wood.

It is in continuing strictly to observe the two foregoing rules, viz. to furnish every part of the tree as equally as possible with bearing wood, and not to lay the branches in too close together, that the art of pruning fruit trees in general, and particularly wall trees, chiefly consists. The former of these will always be completely effected by pinching off the tops of the young shoots, wherever an increase of wood is wanted, in May, as above directed. But as some have advised the doing of this in June, and others even later, we must remark here, that if we reflect that young shoots made so late in the year have not time to acquire a sufficient strength

and solidity of fibres to resist the winter's frost, May will certainly be found to be a much more proper season: for whoever casts an attentive eye over fruit trees after a hard winter, will find many of their shoots killed by the preceding frost; and if he looks still more closely, he will see, that most, if not all, of these have been injudiciously forced out in a too late season. It is almost needless to say that April, which others again recommend for this work, is too early; because the wounded branch would then be in danger of being destroyed by a frosty night. If these directions are judiciously followed, it will not be necessary to touch any fruit tree with a knife in the summer: and that the avoiding of this will be of infinite service to every species of them, is manifest from the many accidents to which they are liable when cut too much at that season. All the soft, tender, and pithy wooded sorts, such especially as the peach tree, require a considerable time to heal their wounds, when these are great, and in the mean while wet and rain easily soak into the wounded parts, so as frequently to make the branches canker and die.

As to the distance at which the branches of fruit trees, or rather the shoots of those branches, should be trained against a wall; nature gives us a sure guide, if we but attend to the size of the fruit and of the leaves: for it should be such that neither of these upon an upper branch may touch the branch underneath.

The winter pruning, as it is called, of fruit trees is commonly performed in February or March: but the best season for it is in October, when their leaves begin to fall; for that will be early enough for their wounds to heal before the frost comes on, so that there will be no danger of their being hurt thereby. Thus all the ascending sap in the spring will be employed to nourish only those useful parts of the branches which are left; whereas, if they are not pruned till February, the greatest part of the sap then in motion in the branches, as may be observed by the swelling of the buds, will be drawn up to the extreme parts of the branches, to nourish blossoms which must afterwards be cut off: for the extreme buds of strong shoots always swell sooner than most of the lower ones, and constantly draw from those below.

It is the constant practice of gardeners, founded upon long experience, to prune weak trees early in the winter, that they may be less endangered by the cutting, and luxuriant trees late in the spring, in order to check their luxuriance. See PRUNING.

WALNUT-TREE, *Juglans*, in botany, a genus producing male and female flowers on the same tree; the male flowers are disposed in an oblong, cylindrical, imbricated amentum; the corolla of each flower is divided into six plane, equal, and elliptic parts, in the center of which is situated a number of very short filaments, topped with erect, acuminate antheræ; the female flowers grow in small clusters, sitting close to the branches; the corolla of each is divided into four erect pointed segments; the fruit is a large, oval, dry, and unilocular drupe, inclosing a large oval nut with netted furrows, containing a kernel with four lobes, which are variously furrowed.

This tree was formerly held in great esteem in this country, for its wood, which is, in fact, often very finely veined; but, on account of its aptness to be worm-eaten, it has of late given place to the beautiful and much sounder mahogany, with which our cabinet-makers have been pretty plentifully supplied from the British settlements in the West Indies.

As an useful fruit tree, independent of its timber, which is, however, still of good value, it merits the husbandman's attention; nor can the gentleman easily find a more stately one to adorn his park with, or to form a noble avenue to his mansion.

These trees are raised from their nuts, which it is best to keep in dry sand, with their outer covers on, till February; that being the right time for planting them. If they are intended for timber trees, they should be sown in the places where they are to remain, in order that the breaking or otherwise shortening of their roots, and especially those of the tap kind, may not stint their growth,

growth, and make them run out in branches: but if they are designed for fruit, their fertility will be increased by transplanting them, because their down-right roots, which are those that chiefly encourage the luxuriant growth of wood in all sorts of trees, will be thereby checked, and they will be made, in lieu of them, to strike out numbers of lateral roots, which, as experience has proved, always conduce greatly to the production of the largest and fairest fruit. The most proper season for transplanting them is when their leaves begin to decay; and the best age, when they have had three or four years growth in the nursery. Mr. Miller says he has frequently experienced that there is little danger of their succeeding, although they be eight or ten years old when they are transplanted: but, however that may be, it is certain that they will root best, grow largest, and last longest, if they are removed young. The less their branches are cut at the time of transplanting, or indeed at any time after, the better they will prosper; for much lopping often causes them to decay: but if there be a necessity for taking off any of their boughs, it should be done early in September, that the wound may have time to heal before the cold and wet comes on. It is likewise essential to cut the branch off quite close to the trunk, lest the stump which is left should decay, and rot the body of the tree; to prevent which, especially if the wound be large, it will be right to smooth it well with a chissel, and then to cover it over carefully with a cement of clay or wax, as in the case of grafting, with a piece of tarpawling, or of sheet lead, over that.

These trees should not be planted nearer together than forty feet, and more may be yet better, if they are designed for fruit. They delight in a firm, rich, loamy soil, or such as is inclinable to chalk or marl; and they will thrive very well in stony ground, or on chalky hills, as is evident from those large plantations near Leatherhead, Godstone, and Carshalton in Surry, where great numbers of these trees planted upon the Downs produce annually large quantities of fruit, to the no small advantage of their owners.

In order to preserve this fruit, it should be left upon the tree till it is thoroughly ripe, and then, as it would be exceedingly troublesome to gather it by hand, it may be bearen off, but not with such violence as is commonly used, from a mistaken notion that the tree is improved thereby: for most certainly it cannot be benefited by that rough way of forcing off the young wood upon which this fruit grows. The nuts thus obtained should be laid in heaps for two or three days, after which they should be spread out, and when they have parted from their husks, which they will then soon do, and have afterwards been well dried in the sun, to remove the moisture of their shells, which would otherwise make them mould, they should be laid up a dry place, where neither mice nor other vermin can get at them. In this manner they will remain good for four or five months: or, which is a yet better way, and will keep them still longer, let them, when their outward moisture has been dried by the sun, be put up in jars or other close vessels, with dry sand between their interstices. The laying of them for four or five hours in an oven gently heated, as is the practice of some, will indeed dry the gum, and prevent their sprouting; but if the oven is too hot, it will make the kernels shrink, and prevent their being peeled with any tolerable ease.

Were it only for the oil that these nuts afford, the trees which produce them would be worth some care. Mr. Evelyn says that one bushel of them will yield fifteen pounds of peeled kernels, and that these will yield half that weight of oil, which the sooner it is drawn, is the more in quantity, though the drier the nut, the better in quality. He adds, that the lee, or marc of the pressing, is excellent to fatten hogs with. Certainly it would be good manure for land; as are the cakes of linseed, rape, &c. after the oil has been squeezed out of them. The green husks boiled, without any mixture, make a good colour to dye a dark yellow. The kernel being rubbed upon any crack, or chink of a leaking vessel, stops it better than either clay, pitch, or wax.

The French are very fond of the kernels of these nuts scooped out of the shells before they are hardened, with a short broad brass knife; because iron rusts and communicates a disagreeable taste to the kernels. When scooped out, they are steeped in salt and water for a few hours before they are set upon the table, as well to take off all taste of bitterness, as to make them peel with the utmost ease.

WALRUS, in zoology, the English name of the phoca, with canine teeth exerted. See PHOCA.

This is much larger than the sea-calf, or phoca, with the canine teeth covered; growing to the size of the largest ox; the head is very large, and almost of a rounded figure; the eyes are large and prominent; there are no ears, but only an aperture on each side of the head, of an oblong form, and not very large; the nose is obtuse; the nostrils large, and the creature contracts and dilates them at pleasure; the mouth is very large, and the upper part of it furnished with thick and cartilaginous whiskers; the tongue is short, the canine teeth of the upper jaw are of an enormous length and size, and they hang downwards and forwards toward the breast; the creature uses these strange weapons to climb upon the ice, and to hang itself to the rocks in its getting on shore to sleep.

WALTHERIA, in botany, a genus of plants, whose flower consists of five heart-shaped spreading petals, and the same number of short stamina joining at their base: the fruit is an oval unilocular capsule, containing an obtuse seed, which is broadest at the top.

WANLASS, in hunting. Driving the wanlass, is the driving of deer to a stand, that the lord may have a shoot, which is one of the customary services of fiefs.

WAPENTAKE (from the Saxon) the same with what we call a hundred, and more especially in the northern counties beyond the river Trent. There have been several conjectures as to the original of the word; one of which is, that anciently musters were made of the armour and weapons of the inhabitants of every hundred; and from those that could not find sufficient pledges of their good abearing, their weapons were taken away, and given to others; whence it is said this word is derived.

WAR, a contest or difference between princes, states, or large bodies of people, which not being determined by the ordinary measures of equity and justice, is referred to the decision of the sword.

Holy WAR, was that anciently maintained by leagues and croisades, for the recovery of the Holy-land.

WARD, in law-books, a word of divers significations: thus a ward in London, is a part of the city committed to the special charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and the parishes thereof as towns. A forest is also divided into wards, and so are most of our hospitals.

WARD, WARDA, or WARDAGIUM, is also used, in our ancient writings, for the custody of a town or castle, which the tenants and inhabitants were bound to keep at their own charge.

WARD-HOOK, or WADD-HOOK, in gunnery, a rod of staff with an iron end turned serpent-wise, or like a screw, to draw the wadding out of a gun when it is to be unloaded.

WARDEN, or GUARDIAN, one who has the charge or keeping of any person, or thing, by office.

Such is the warden of the Fleet, the keeper of the Fleet-prison; who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

Warden, in an university, is the head of a college; answering to what in other colleges we call the master thereof. Warden, or lord warden of the Cinque Ports, is the governor of these noted havens; who has the authority of an admiral, and sends out writs in his own name. Warden of the mint, is an officer whose business it is to receive the gold and silver bullion brought in by the merchants, to pay them for it, and oversee the other officers.--He is called keeper of the exchange and mint.

WARDROBE, a closet, or little room adjoining to a bed-chamber, serving to dispose and keep a person's apparel in; or for a servant to lodge in, to be at hand to wait, &c.

Wardrobe, in a prince's court, is an apartment where-in his robes, wearing apparel, and other necessities are preserved under the care and direction of proper officers; as the master of the wardrobe, clerk, &c. of the wardrobe.

WARNING-PIECE, in the military art, is the gun which is fired every night about sun-set, to give notice to the drums and trumpets of the army to beat and sound a retreat or tattoo, which is likewise setting the watch.

WARNING-WHEEL, in a clock, is the third or fourth, according to its distance from the first wheel. See the article **CLOCK**.

WARP, in the manufactures, is the threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman by means of his shuttle passes the threads of the woof, to form a cloth, ribbon, fustian, or other matter.

For a woollen stuff to have the necessary qualities, it is required that the threads of the warp be of the same kind of wool, and of the same fineness throughout; that they be sized with Flanders or parchment size, well prepared, and that they be in sufficient number with regard to the breadth of the stuff to be wrought.

To **WARP a ship**, is to shift her from one place to another, when the wind and tide will permit it without danger.

WARRANT, an act, instrument, or obligation, whereby a person authorises another to do something which he otherwise had not a right to do.

Warrant of attorney, is that whereby a man appoints another to do something in his name, and warrants his action.

It seems to differ from a letter of attorney, which passes under the hand and seal of him who makes it, before creditable witnesses; whereas warrant of attorney, in personal, mixed, and some real actions, is put in of course by the attorneys for the plaintiffs or defendants.

WARRANTY, *Warrantia*, a promise or covenant by deed, made by the bargainer for himself and his heirs, to warrant and secure the bargainee and his heirs against all men for enjoying the thing agreed on between them.

WARRANTIA CHARTÆ, a writ that lies for a person who is infeoffed in lands and tenements, with clause of warranty, and is impleaded in an assize, or writ of entry, wherein he cannot vouch or call to warranty. See **VOUCHER**.

WARRANTIA DIEI, a writ which lies in case where a man having a day assigned to appear personally in court to an action wherein he is sued, is, in the mean time, by commandment employed in the king's service; so that he cannot come at the day assigned.

WARREN, *Warrena*, a franchise, or place privileged either by prescription or grant from the king, to keep beasts and fowl of warren in; as rabbits, hares, partridges, pheasants, &c.

By statute 21 Edward III. a warren may lay open, and there is no need of closing it in, as there is a park.

In the setting up a warren, great caution is to be used for the fixing upon a proper place, and a right situation. It should always be upon a small ascent, and exposed to the east or south. The soil that is most suitable, is that which is sandy; for when the soil is clayey or tough, the rabbits find greater difficulty in making their burrows, and never do it so well; and if the soil be boggy or moorish, there would be very little advantage from the warren, for wet is very destructive of these animals.

All due precautions must be taken, that the warren be so contrived, that the rabbits may habituate themselves to it with ease. Many would have it that warrens should be enclosed with walls; but this is a very expensive method, and seems not necessary nor advisable; for we find but very few that are so, and those do not succeed at all the better for it.

The dung of rabbits is a great fertilizer of useless lands, and Mr. Mortimer tells us that he has known

vast crops of rye upon barren lands that have been old warrens well dunged by rabbits; and large oak and ash upon the same, though the soil was very shallow.

WART, *Verruca*, in surgery, a little round hard excrescence arising from the flesh like a pea.

A wart begins at the cutis, and seems to be either an efflorescence of the serum of the blood, which hardening in the surface of the skin, makes a dry tumour; or else some small luxuriance of the little arteries of the cutis, which thrust themselves out, making a pretty sarcoma, which we call a soft wart.

According to the variety of the tumour, it is sometimes whole with a smooth surface, and sometimes chapped and uneven.

The method of cure which deserves to be first mentioned, is by ligature or vincture; this is performed upon such of these excrescences as are slender about the roots, and in a manner pendent, by firmly tying about them a horse-hair, or a filken or linen thread; the warts, being thus deprived of the juices which nourish them, through a constriction of the vessels by the ligature, gradually wither and fall away.

Another method of cure, is the surgeon's instrument, with which the wart is taken up by a hook or forceps, and then very nicely separated by the scissars. The wound is treated for some time with an application of the lapis infernalis, or some other corroding medicine, that if any part of a root should remain, from which a new tubercle might arise, it might be consumed and destroyed.

The cure by caustics is best performed by cutting off the hard upper part of the wart, with a razor or scissars, and then surrounding its bottom with a circle of wax to prevent the spreading of the remedies; to touch it daily with oil of tartar, spirit of salt, aqua fortis, or butter of antimony.

The cure by cautery is performed by choosing a cautery of a proper size, and with that burning down to the root of the wart. This is the most painful of all the methods of extirpating these excrescences, but the pain is but for a moment, and the warts extirpated this way never return.

The cure by evulsion, is performed by anointing them with softening ointment, and then seizing them artfully between the thumb and fore-finger, and forcibly wrenching them out. This is a mountebank method, and a bad one; for it is not only very painful, but the warts commonly grow up again.

When warts are found to look livid and blue, it is best to let them alone entirely; because, when irritated, they frequently degenerate into a cancer. See **CANCER**.

WART-WORT, *Tithymalus*, in botany. See **TITHYMALUS**.

WASH, among distillers, the fermentable liquor used by the malt-distillers. See **DISTILLERY**.

It should be about the strength of the ten shilling small-beer; and if the spirit be expected fine, it had better be too thin than too thick. It is only made by mixing the water hot with the malt ground into meal. If the water be too hot, the mixture will become gluey; and if too cool, a part of the virtue of the malt will be lost. Under the right application of the water is to be considered the proper manner of agitating the mass, so that all the parts of the aqueous fluid may come fully and freely in contact with the soluble particles of the subject.

When once the water is well saturated by standing on the malt a proper time, it must be drawn off, and fresh poured on, till at length the whole virtue, or all the sugary sweetness of the malt, is extracted, and nothing but a fixed husky matter remains behind, incapable of being farther dissolved by the action of hot or boiling water; or of being advantageously washed or rinsed out by the bare affusion of cold.

This artificial and external agitation or stirring about of the mass, is necessary, not only in the common way of brewing for the malt-distillery, but also in that more expeditious way, now in use with some, of reducing the operations of brewing and fermenting to one, and grinding the malt to a fine meal, which is to be kept in the

wash during the whole time, and even put into the still with it and worked together.

The stirring may be repeated to great advantage more than once in each operation, as at the affusion of every parcel of fresh water, in the common way, and at any shortly distant times in the short way, in which it is of greater service.

The action of fermentation works such a change in the body of the tincture or solution, called the wash, as to render it separable by distillation, into parcels of matter that are specifically different, and of a nature entirely foreign to what the same liquor would have yielded without the fermentation.

WASHING, in painting, is when a design, drawn with a pen or crayon, has some one colour laid over it with a pencil, as Indian-ink, bistre, or the like, to make it appear the more natural, by adding the shadow of prominences, apertures, &c. and by imitating the particular matters, of which the thing is supposed to consist.

Thus they wash with a pale red to imitate brick and tile; with a pale Indian blue, to imitate water and slate; with green, for trees and meadows; with saffron or French-berries, for gold or brassy; and with several colours for marbles. These washes are usually given in equal tints or degrees throughout, which are afterwards brought down and softened over the lights with fair water, and strengthened with deeper colours for the shadows.

Some colours are of such a gritty, sandy nature, that it is impossible to grind them so fine as some curious works require; therefore, in order to get forth the flour and fineness of the colour, it must be washed, which is done thus: Take what quantity of colour you please to wash, and put it into a vessel of fair water; stir it about till the water be all coloured therewith, and if any filth swim on the top of the water, scum it clean off; and, when you think the grossest of the colour is settled at the bottom, then pour off that water into another earthen vessel, that is large enough to contain the first vessel full of water four or five times; then pour more water into the first vessel, stir the colour that remains till the water be thick; and after it is a little settled, pour the water also into a second vessel, and fill the first vessel again with water, stirring it as before; continue to do this till you find all the finest of the colour drawn forth, and none but coarse gritty stuff remain in the bottom; then let this water in the second vessel stand to settle till it is perfectly clear, and that all the colour be sunk to the bottom; which when you perceive, then pour the water clear from it, and reserve the colour in the bottom for use, which must be perfectly dried before you mix it with oil to work.

The colours thus ordered, are red lead, blue and green bice, verditer, blue, green smalt, and Spanish brown, when you would cleanse it well from stones for some fine work, as also yellow ochre, when you intend to make gold size of it.

WASHING of Ores, the purifying an ore of any metal, by means of water, which would otherwise render it difficult of fusion; this operation Cramer orders to be done as follows: Break the ore to a coarse powder in an iron mortar, weigh twenty or thirty decimastical centners of it, put them into the washing trough, and pour some water upon them, that the ore may be thoroughly moist; then have a vessel full of water, the diameter of which must be a little larger than the length of the trough; take the trough with the left hand, by the top of the hinder part, and dipping it horizontally into the water, move it gently with the right-hand from the forepart of the trough, which is always to be made the shallower part of it, toward the hinder part, which is deeper; then take out the trough; and incline it a little on the forepart, that the water may run out, and the heavier metallic part remain at the bottom; repeat this several times till the remains at the bottom of the trough are quite pure. If the stone in which the ore is lodged be too hard for powdering in its natural state, as the flinty and debased crystalline ones commonly are, the whole must be calcined, and quenched in cold wa-

ter several times over, and afterwards powdered and washed in this manner: When it is thus washed, assay a centner of it, and from the bead of metal this yields, it will be easy to estimate the value of the ore.

WASHING, or WASHES, among goldsmiths, coiners, &c. are the lotions whereby they recover the particles of gold and silver out of the sweep, that is, ashes, earths, sweepings, &c.

This is either performed by simply washing them again and again, or by putting them in the washing-mill.

To make one of these washes, they not only gather together the ashes of the furnaces, and sweepings of the work-shops, but they also break and pound the old earthen crucibles and the very bricks of which the furnaces are built; little particles of gold, &c. being found to stick to them by the crackling natural to those metals, when in their last degree of heat.

These matters, being ground and mixed together, are put in large wooden-basons, where they are washed in several waters, which run off by inclination into troughs underneath; carrying with them the earth, and the insensible particles of the metals, and only leaving behind them the larger and more considerable ones which are visible to the eye, and taken out by the hand without more trouble.

To get out the finer parts gone off with the earth, they use quicksilver and a washing-mill. This mill consists of a large wooden trough, at the bottom of which are two metalline parts, serving as mill-stones; the lower being convex, and the upper, which is in form of a cross, concave.

A-top is a winch placed horizontally, which turns the upper piece round; and at bottom, a bung to let out the water and earth, when sufficiently ground.

To have a wash, then, the trough is filled with common water, into which they cast thirty or forty pounds of quicksilver, and two or three gallons of the matter remaining from the first lotion. Then turning the winch, they give motion to the upper mill-stone, which grinding the matter and the quicksilver violently together, the particles of gold and silver become the more easily amalgamated therewith. This work they continue for two hours, when, opening the bung, the water and earth run out, and a fresh quantity is put in.

The earths are easily thus passed thro' the mill three times, and the same quantity of mercury usually serves all the three times. When there is nothing left in the mill but the mercury united with the gold or silver which it has amalgamated, they take it out, and washing it in divers waters, they put it in a ticken-bag, and lay it in a press to squeeze out the water, and the loose quicksilver; the remaining quicksilver they evaporate by fire, in a retort, or an alembic. The metal which remains they refine with lead, or part it with aquafortis.

WASP, in zoology, an insect with four wings, and six feet; its body is yellow, with black triangular spots: the common wasp breeds in the ground. There is another kind much more fierce, but very rare: these breed in woods and mountains; they are larger, and have broader bodies, and much more black about them; their sting is so large, that it seems disproportioned to the size of their bodies.

To these are to be added the ichneumon wasps, which are smaller than the others, and have very slender bodies, but of the same colours with the common kind: they usually live in the holes of mud-walls, and make a sort of porch of mud before the doors of their habitations.

There is also another wasp common about Vienna; this is three times as large as the common kind, and seems of two different species, the one having rough antennæ, and the other smooth; they are both variegated with black and a bright yellow. *Mouffer's Hist. Insect.*

WASP-FLY, in natural history, a species of fly, having very much the external figure of a wasp, but harmless, without a sting, and with only two wings.

WASP TIPULA, in natural history, the name of an insect described by Mr. Reaumur, and being properly a tipula, or long-legs, tho' greatly resembling a wasp.

WAST,

WAST, or **WASTE**, *Vastum*, in law, has divers significations. It is used for a spoil, made either in houses, woods, lands, &c. by the tenants for life, or for years, to the prejudice of the heir, or of him in reversion or remainder.

Upon this the writ of waste is brought for the recovery of the thing wasted, and treble damages.

WASTE of the Forest, is properly where a man cuts down his own woods within the forest, without licence of the king or lord chief justice in eyre.

WASTE is also taken for those lands which are not in any man's occupation, but lie common.

They seem to be so called, because the lord cannot make such profit of them, as of his other lands, by reason of the use others have thereof, for passing to and fro. Upon this none may build, cut down trees, &c. without the lord's licence.

WASTE of a Ship, is that part of her between the main and fore-mast.

WASTE-BOARDS, are boards sometimes set upon the side of a boat, or other vessel, to keep the sea from breaking into her.

WASTE-CLOTHES, in a ship of war, the same with fights.

WATCH, in the art of war, a number of men posted at any passage, or a company of the guards who go on the patrol.

Watch also implies a person posted as a spy in any place, to have an eye thereto, and to give notice of what passes. A watch is properly intended for the apprehending of rogues in the night, as ward is for the like purpose in the day-time; and for default to watch and ward, the township, &c. is punishable. It is ordained, that in all towns between Michaelmas day and the day of Ascension, there shall be night-watches kept in each city, with six men at every gate, and six or four in a town. Also every borough is to have twelve men to watch therein, or otherwise in proportion to the number of the inhabitants in the place, from sun-set to sun-rising, who are to arrest strangers suspected, and disturbers of the peace, &c. and may justify the detaining of them till the morning; or they may deliver them to the constable, in order to be carried before a justice.

At sea, the term watch denotes a measure or space of four hours, because half the ship's company watch, and do duty in their turns, so long at a time; and they are termed star-board watch, and lar-board watch.

WATCH is also used for a small portable movement or machine for the measuring of time; having its motion regulated by a spiral spring. See **SPRING**.

Watches, strictly taken, are all such movements as shew the parts of time; as clocks are such as publish it, by striking on a bell, &c. But, commonly, the name watch is appropriated to such as are carried in the pocket, and clock to the large movements, whether they strike or not. See the article **CLOCK**.

The several members of the watch part are, 1. The ballance, consisting of the rim, which is its circular part; and the verge, which is its spindle, to which belong the two pallets or levers that play in the teeth of the crown-wheel. 2. The potence, or pottance, which is the strong stud in pocket watches, whereon the lower pivot of the verge plays, and in the middle of which one pivot of the ballance-wheel plays; the bottom of the potence is called the foot, the middle part the nose, and the upper part the shoulder. 3. The cock, which is the piece covering the ballance. 4. The regulator or pendulum spring, which is the small spring in new pocket watches, underneath the ballance. 5. The pendulum, whose parts are the verge, pallets, cocks, and the bob. 6. The wheels, which are the crown-wheel in pocket pieces, and the swing-wheel in pendulums, serving to drive the ballance or pendulum. 7. The contrate-wheel, which is that next the crown wheel, &c. and whose teeth and hoop lie contrary to those of other wheels; whence the name. 8. The great or first wheel, which is that the fusee, &c. immediately drives: after which are the second wheel, third wheel, &c. 9. Lastly, between the frame and dial plate, is the pinion of report, which is that fixed on the arbor of

the great wheel, and serves to drive the dial-wheel, as that serves to carry the hand.

Spring, or **Pendulum WATCHES**, are pretty much upon the same principle with pendulum clocks, whence their denomination.

If a pendulum describing little arches of a circle make vibrations of unequal length in equal times, it is by reason it describes the greater with greater velocity. For the same reason a spring put in motion, and making greater or less vibrations, as it is more or less stiff, and as it has a greater or less degree of motion given it, performs them nearly in equal times. Hence, as the vibrations of the pendulum had been applied to large clocks to rectify the inequality of their motions; so, to correct the unequal motions of the ballance of watches, a spring is added, by the isochronism of whose vibrations the correction is to be effected.

The spring is usually wound into a spiral, that, in the little compass allotted it, it may be as long as possible, and may have strength enough not to be mastered and dragged about by the inequalities of the ballance it is to regulate.

The vibrations of the two parts, viz. the spring and ballance, should be of some length; only so adjusted, as that the spring, being more regular in the length of its vibrations than the ballance, may on occasion communicate its regularity thereto.

The invention of spring or pocket watches, is owing to the artists of the present age. It is true, we find mention made of a watch presented to Charles V. in the history of that prince; but this in all probability was no more than a kind of a clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1670.

In effect, it is between Dr. Hooke and Mr. Huygens, that the glory of this excellent invention lies, but to which of them it properly belongs, is greatly disputed; the English ascribe it to the former, and the French, Dutch, &c. to the latter. Mr. Derham, in his *Artificial Clock-maker*, says plainly that Dr. Hook was the inventor; and adds, that he contrived various ways of regulation. One was with a load-stone: another with a tender straight spring, one end whereof played backwards and forwards, with the ballance; so that the ballance was to the spring, as the bob to a pendulum; and the spring, as the rod thereof. A third method was with two ballances, of which there were divers sorts, some having a spiral spring to the ballance for a regulator, and others without. But the way that prevailed, and continues in mode, was with one ballance and one spring running round the upper part of the verge thereof; though this has a disadvantage which those of two springs, &c. were free from, in that a sudden jerk or confused shake will alter its vibrations, and put it in an unusual hurry.

The time of these inventions was about the year 1658, as appears, among other evidences, from an inscription on one of the double-ballance watches presented to king Charles II. viz. Robert Hooke invent. 1658, T. Tompion fecit, 16. The invention presently got into reputation, both at home and abroad; and two of them were sent for by the dauphin of France.

Soon after this, Mr. Huygens's watch, with a spiral spring, got abroad, and made as great noise in England, as if the longitude could be found out by it. It is certain, however, that his invention was later than the year 1673, when his book *De Horol. Oscillat.* was published, wherein he has not one word of this, though he has of several other contrivances in the same way. For the principles of Mr. Harrison's watch for finding the longitude at sea, see **LONGITUDE**.

Astronomical WATCH, a machine invented by Mr. Neale, for solving several astronomical problems. It has two glasses; that in the front covers a dial plate, as in common watches; the other on the back-side, covers a plate forming a segment of a globe, on which are drawn twenty-four meridian lines, with the names of so many countries, at 15° difference of longitude from each other. This plate makes an entire revolution in twenty-four hours; and, consequently every country thereon passes

passes by the sun. Round this plate is a circle divided into twenty-four hours, also at rest; by means of which, when the moveable plate is made to correspond with the true time, shewn by the hands on the common side, the time of day or night, at the several countries specified, is shewn by the hour-circle. Round the moveable plate, and between it and the circle of hours above described, moves a narrow circle, on which is engraved the moon's age; and over $29\frac{1}{2}$ is placed an ivory ball, representing the moon: and at right angles each way, are placed two pins, one eastward, and the other westward; by means of which, the time of the moon's rising, southing, and setting, at those different places, is shewn in a very entertaining manner. Several other useful astronomical problems may also be solved thereby.

Striking WATCH, one which, besides the common watch-work for measuring time, has a clock-part for striking the hours; so that, properly speaking, they are pocket-clocks. See *CLOCK*.

Repeating WATCH, one that by only pulling a string, pushing in a pin, &c. repeats the hour, quarter, or minute, at any time of the day or night.

WATCHING, or *WAKEFULNESS*, *Insomnia*, in medicine, is produced by too great a determination of the nervous fluid to the organs of the senses, whereby these organs are prepared to receive, readily, any impression from external objects, which they propagate to the brain, and furnish the soul with divers occasions of thinking. This extraordinary flux of spirits may have two causes; for, 1. The sensible objects may strike the organ with too much force. In which case, the animal spirits being violently agitated, and those agitations continued by the nerves to the brain, they give a like motion to the brain itself; the necessary consequence of which is, that the animal must wake. Thus, a loud shriek, pains, headach, gripes, coughing, &c. cause waking. And the soul's being oppressed with cares, or deeply engaged in thinking, contributes to the same, since, as it acts by the ministry of the spirits, any cares or meditations that keep them in motion, must produce watchfulness. Of this kind are those inveterate wakings of melancholic persons, some of whom have been known to pass three or four weeks without a wink of sleep.

2. The other cause is in the spirits themselves, which have some extraordinary disposition to receive motion, or to persist in it: as from their too great heat, or that of the brain, in fevers, &c. Hence it is, that the disorder is most frequent in summer, in the heat of youth, &c.

Long fasting has the same effect; the want of food subtilizing the spirits, and drying the brain. The same is likewise an ordinary symptom in old age, by reason the pores of the brain and nerves having been much widened by the continual passage of spirits for a great number of years, the spirits now pass and repass through them with too much ease, and need not any extraordinary motion to keep the mind awake.

There are instances of waking forty-five nights successively; and we even read of a melancholy person, who never slept once in fourteen months. Such watchings usually degenerate into madness.

When the cause is known, it must be removed, if possible, and the irritated spirits must be appeased with emulsions, especially of poppy seeds, or with the thebaic tincture, or theriaca, and other opiates in general, not neglecting the original diseases. In fevers, a moist soft moistening diet is beneficial; as also preparations of barley, emulsions of poppy-seeds and almonds, decoctions of scorzonera roots, almond cream, and winter flummery used as aliment: likewise tea made of cowslip flowers, and gentle laxatives.

When the patient is restless and wakeful the night before a crisis, no hypnotics should be given.

When there is no other disease, the patient should shun all care and intense thinking, especially in the evening: he should also use exercise, and eat light suppers. If it is caused by pains, they should be appeased by antispasmodics, things which temperate, and diaphoretics; and if these will not do, mild opiates must be added. In old persons, all care and solitude must be ba-

nished; the mind should be quiet, and the moderate use of generous wine may be allowed in the evening; likewise medicines of amber and musk will be proper, and confectio alkermes or theriaca with wine. The drinking of hot-water, and principally coffee, must be forbid after dinner.

WATER, in general, implies a pellucid fluid, convertible into ice by cold; naturally pervading the strata of the earth, and flowing or stagnating on its surface.

Pure water would require a definition very different from this, that of a limpid and colourless liquor, without smell or taste, simple, and volatile. But such a definition would not include the waters impregnated with metalline, stony, saline, and other fossile particles.

Waters may be arranged under two general divisions:

1. The common waters serving for the ordinary purposes of life.

2. The waters impregnated with peculiar mineral substances. The differences of common water, arising from the circumstances of stagnation or motion, or of its containing more or less of those stony particles, which it always contains in some degree, are not so essential, as to prevent the whole from being considered as of only one kind.

The waters impregnated with peculiar mineral substances, on the other hand, differ essentially, in regard to the several impregnating matters, and are properly arranged, according to them, into four kinds:

1. Waters impregnated with metalline particles.

2. Waters impregnated with saline particles.

3. Waters impregnated with sulphureous particles.

4. Waters impregnated with terrene particles.

Common WATERS, or such as serve the ordinary purposes of life.

A fluid of this kind, so well calculated for the dissolving and sustaining, in a state of solution, many of the subjects of the mineral kingdom, cannot but, in its passage through the earth, be more or less impregnated with many of the bodies it washes in its course. We accordingly meet with it in different places, impregnated in various manners and degrees, with various substances, some in greater, some less proportion, and some more, some less perceptible to our senses. According to the testimony of those imperfect judges, we usually divide water into two general kinds, the simple and the medicinal.

Simple, or pure water, in a just sense of the word, is not met with any where: heterogeneous matter, and that in a large quantity, may be separated from such as appears the purest and most simple; but we include, in a more general manner, under the first of these terms, all those waters which have no smell or taste of any extraneous matter, nor any particular effect on the body; and under the latter we include all those whose smell, taste, or other obvious qualities, denote their containing saline, metalline, or other mineral particles in them, and whose effects on the body correspond with these notices of their contents.

The waters of the first general kind are used in the common occasions of life, those of the other are taken as medicines to restore decayed health.

Simple water, to use the received phrase, is a pellucid colourless fluid, insipid to the taste, and without smell; we meet with this under different circumstances, and accordingly divide it into spring-water, well-water, river-water, pond-water, rain-water, and snow-water. The first is the water furnished us from the bowels of the earth, and is continually fresh supplied; the second is the same water, only with the difference of its remaining long in the same place before we have it; the third is a mixture of the first, and of fresh vapours raised from the sea and fresh waters, and descending in rains. The two first are almost invariably the same; the latter is subject to a thousand changes, from the matters accidentally washed into it by the torrents occasioned by rains; but it has the advantage of being in continual motion. The fourth is much the same in its nature with this, but is rather more owing to water that has been raised in vapour, and has fallen again in rain; this has also the disadvantage of standing and stagnating

in its place. The fifth has the advantage of being wholly raised in vapour, and, as it were, distilled by nature: it is, consequently, purer than any of the others; but there are so many kinds of particles capable of rising with the water in vapour, that it never can be, nor ever is perfectly pure. The last has all the advantage of this, and the additional one, of having been frozen in its passage, and thus having passed through an operation very well calculated for the separating of heterogeneities of many kinds.

Upon the whole, the last, or snow-water, bids fair for being the purest and fittest for our common use, of any that comes in our way; yet even this we have found, by experiments, not to be absolutely pure.

It has been objected to snow-water, that it occasions swellings in the throats of people who are obliged to drink it; but if we examine strictly into the origin of this charge against it, we shall be induced to acquit it. Errors are easily taken up and quickly propagated. It has been early observed, that the people who inhabit the Alps had swelled throats almost universally; one of the first people who made this observation, attributed it to their drinking a water different from that which other people drank, it being, at least for a great part of the year, little other than the melted snow, with which the tops of those mountains are covered. Snow-water thus got the scandal of occasioning an ill effect, which people did not see the cause of, and it has retained its ill name, on the occasion, to this day. Things are not, however, the more true, for being generally received as truths, nor does this seem to deserve at all the credit that it has had for so many ages. We see a fair trial of the effects of snow-water in our sailors, who attend the Greenland whale-fishery: these people, for many months, have no other drink than snow-water, or they eat snow by way of drinking; yet swelled throats are not found to be the consequence. On the other hand, we have a part of England, in which swelled throats, among the women at least, are as common, if not as great, as among the Alpines. The women of many parts of Derbyshire are almost universally subject to them; yet they do not drink snow-water any more than their neighbours.

These are two simple facts, which one would wonder no body had enquired into before; but if by these it appears that snow-water may be drank without occasioning swelled throats, and that swelled throats may be a general disorder in certain places, without the drinking of snow-water, it should seem very fair to conclude, that it is not snow-water which occasions them in the Alps: tho' people have very firmly believed it for 2000 years; and when we have got rid of this vulgar prejudice, we shall find nothing to countenance the censure the world has so long passed upon what is doubtless the best and purest water we are naturally acquainted with.

All waters, as they are more pure, are more soft: this, as the purest, is the softest of all. Rain-water comes next to this; but both by experiments and analysis, is found to be inferior to it: after rain-water, those waters are the softest which are most formed of this, except when altered for the worse by stagnation, or other accidents. Spring-water, though the clearest and most tempting of all to look at, is the least pure, and, of all others, the least fit for common use; and, consequently, the other waters we meet with, which are all composed of a mixture of spring and rain-water, are the better and fitter for all the purposes of life, as they contain more of the rain-water, and less of the other.

The eye, we see, by the instance of the pellucidity and seeming purity of spring-water, is no adequate judge on this occasion. It will teach us, indeed, not to use foul or dirty water, which would carry mud, and a multitude of other things we never ought or intend to swallow, into our stomachs; but it leaves us in the dark as to those contents of water, which, in however great quantity, may be suspended imperceptibly in it. In this case we are to judge by the effects of the water, and after having set aside all stagnating water, as such, for very obvious reasons, we are to consider the effects of the others in and out of the body.

Such water as sits light upon the stomach is to be preferred to that which is heavier there: it should have no sensible quality but that of mere water on the body. Water that boils soonest and cools soonest is to be preferred, and such as boils garden stuff the quickest, and mixes the most readily and perfectly with soap.

The water produced from melted snow is superior to all other kinds in these several respects, and is, doubtless, the last of all waters to be justly charged with the mischievous effects ascribed to it by the people who suppose that the swelled throats of the Alpines are occasioned by it: what is the occasion of so odd an effect, is not the business of this article to enquire into. Only it may be observed by the bye, that the Alps are known to abound in many places, and, perhaps, do so in many more, with the same sort of mineral and fossil substances, that are found in our county of Derbyshire: and that the water the people who inhabit those mountains drink, may be the occasion of the disorder, though it is very evident that it does not produce it, as a solution of snow.

The extraneous matter generally and universally contained in all waters, in its natural state, is spar, a fossil substance, which, though we are not able to dissolve in water by any artificial means, yet we have the strength of all proofs, that it is naturally dissolved and sustained in it, because we can, at all times, separate it from it in a solid form. This spar is, in itself, a pellucid fossil, but it is usually associated with more or less earth, often with other particles. The earth gives it a foulness and opacity in its mixed state, which, though not perceptible in the water, never fails to be so in the solid matter, when separated from it.

This spar is, in some measure, separated from all water by the common means of evaporation; and even in cases wherein the operation is not carried to such a height as to separate it by an absolute evaporation to a dryness in a large quantity at once; yet, in proportion to the water evaporated, a quantity of it is always precipitated to the bottom and sides of the vessel, which, though too small to be perceptible, when only the produce of a few of these operations, yet, by degrees, increases in vessels frequently used and not cleaned, and shews itself in a very evident manner.

This is the origin of that stony matter found concreted round the sides of our tea-kettles; the several boilings of water in which add each their precipitation to the former, and the vessel never being cleaned from it, the consequence of repeated boilings, for a long time, is a crust of sparry matter, of a thickness proportioned to the length of time it has been forming.

This substance, when examined, will be found to be just what has already been mentioned, as the precipitation of all water, a spar, more or less fouled with earth, according to the clearness or impurity of the water, and containing also more or less of crystalline particles. The water of rivers contains less of this spar than that of springs; and this is owing to its being composed in part of rain-water, which, tho' not absolutely free from it, contains much less than that of springs; and, accordingly, those rivers which are most dependent on rain, carry least of this in their water. The several different springs, tho' they all carry greatly more of it than river or pond-water, yet differ greatly from one another in the quantity they hold of it; and, accordingly, we see the water of rivers is a much longer time in forming any considerable crust in these vessels, than that of springs; and that the water of some springs produces it much quicker than that of others.

The uses of common water in the various occasions of life, and its service in the animal œconomy, are sufficiently known. Whatever are its virtues, caution is to be used as to the state in which it is drank. People in health ought to drink it in a temperate state; those who are sick ought, in whatever form it comes to them, to have it warmed. Water drank extremely cold, for a constancy, injures the nerves, and occasions torpors, and even paralytic disorders of the internal parts: it often also, gives violent cholics, and hurts the digestion; if drank in this state, at a time when the body is heated with labour or exercise, there is no end of the disorders it may occasion, nor any thing more fatal than the mischiefs

chiefs, that may attend it. On the other hand, warm water taken too copiously, and for a continuance, is not without its ill consequences; it too much relaxes the fibres of the stomach, and the food, in consequence of this, passes off not half digested.

Our Dr. Hancock has given cold water great praises as a medicine; he tells us of his having cured fevers of many kinds, and a number of other distempers, by giving a draught of it in the beginning of the disease, and suffering it to take its natural course, and act as a sudorific. He orders six or eight ounces of it to be given to a child, a pint or a quart to grown persons, at the coming on of the disease, or in intermittents, or in coming on of the fit. They are to be laid in bed first, but its operation is not to be promoted by any additions of covering: the whole body becomes soon after warm, and after this, usually, a plentiful perspiration succeeds. The first dose frequently cures in intermittents, but a second, or third, he tells us, very rarely fail.

The cold water method has been carried much farther in some countries, than it has been proposed with us. People have been made to take it in chronic cases, to the quantity of four, five, or six quarts a day, and this for a continuance of fourteen days, or three weeks, and little or no kind of any food allowed during the whole course. Some have been starved by this meagre discipline; but it is affirmed that many have been cured by it.

In this practice, it is not expected that the water should sweat the patient, as Dr. Hancock would have it do; care is taken, on the contrary, that they are not suffered to sweat after it, but it is to be voided by stool and urine: it is a method of practice, however, that is not likely to be put in practice among us.

Another great use of water, in a medicinal way, is in baths of the cold and of the warm kind. The latter are more agreeable to the patient, and very great effects have been produced from the former.

Warm baths are emollient, relaxing, and attenuating; they promote perspiration, and take off the sense of weariness and pain; they are often of great service in nephritic cases, and serve happily to bring out eruptions on the skin in many cases, when nature is labouring at that end, and is oppressed in many other respects, because not able to effect it.

Warm baths, however, are not to be indiscriminately advised to all people; those of plethoric habits, and those in danger of paralytic complaints, are by no means to use them; and they are, in general, to be avoided in fevers, deliriums, diarrhæas, and hæmorrhages of whatever kind.

Cold baths have the exact contrary effects to the hot ones; they contract as much as the other relax the fibres. The best way of going into them is in a morning; and exercise, or else a warm bed, is to be recommended afterwards.

The Romans, we are told, had a method of plunging themselves out of their hot baths into their cold ones. They did this to preserve health, and to give them strength and spirits. The American Indians are found in possession of a secret of the same kind, but they use it as a cure for diseases. They sweat themselves between hot turfs of earth, and in the midst of this plunge themselves into beds of snow: a strange wild method! but not attended with the ill consequences among them, that might be imagined.

Medicinal Waters, are such, as beside the sparry, earthy, and crystalline matter contained in all water, are impregnated with other mineral particles, and these either of the metalline or saline kind. These waters are distinguished by two general kinds, as they come forth out of the ground, either hot or cold. The names by which they are called are *thermæ* and *acidulæ*. The name of *thermæ* is properly enough given to the hot ones, expressing as much; but the other term, *acidulæ*, is not quite apposite to the cold ones, because they rarely contain an acid salt, but always an alkaline one. It was given them on account of a certain urinous, or, as some express it, a subacid taste, which many of the cold mineral waters have, when fresh drawn from the spring.

The particles with which the waters are impregnated, are, in general, of four kinds, metalline, saline, sulphureous, or terrene. They cannot but be extremely frequent, as the substances they impregnate one or other of them, are in almost all parts of the earth. There are more than a thousand in Germany alone. Our own Island affords a vast number, and scarce any known parts of the world but abound with them.

Copper and iron, being the two metals most easily soluble in water, are the most common in the impregnation of springs. The cupreous waters are found in places where there are mountains abounding in copper; and some of them are so strongly impregnated with it, that they carry off the particles of iron laid in them, and leave the copper they contained in their place. This is called transmuting iron into copper; but that pompous name was only given to the operation, from an ignorance of the manner in which it was performed. The ferrugineous waters are much more frequent than the cupreous, and of much greater use to the world. These, with the iron, usually contain many other extraneous particles, earthy, and of other kinds, as appears by evaporation, and always a peculiar alkaline salt, to which they owe a great part of their qualities. They all have more or less of the ferrugineous taste, and all discover the metal they contain, by putting a little powder of galls in them, as they become purple, and afterwards black like ink, on that admixture. A number of other vegetable substances will answer the same purpose, but not so certainly and readily as galls, where the ferrugineous matter is in very small quantity.

The alkali that is in all these waters, is somewhat of the nature of the *natrum* of the ancients; being a native fixed alkali; it differs from the common alkalies, in that it is reducible to crystals like the *natrum*, and from that in no less essential a point than the figure of those crystals. Both these salts have been, indeed, of a quadrangular form, but those of the *natrum* are truncated at the ends; those of the alkaline salt of the chalybeate waters terminate in pyramids in the manner of those of nitre, and of the same number of sides with the columns. This salt has all the properties and qualities of the common fixed alkaline salts produced from vegetables; mixed with acids, it effervesces, and produces neutral salts; with an infusion of violets, it turns green; with a solution of corrosive sublimate, it precipitates a yellow powder from it; and, finally, with crude sal armoniac, it produces an urinous smell.

It is of the utmost importance to the waters of this kind, they contain no other alkali, and yet there is no accounting for their properties rationally, without supposing one, nor any imitating them with tolerable success without such a salt. The common fixed alkali of tartar will, however, answer the purpose on these occasions, and with that and a solution of the pyrites, or of iron by the help of an acid, a water may be prepared, greatly resembling the natural chalybeate ones, even the finest not excepted; and by varying the proportions, the liquor may be brought to imitate not only the taste, but the qualities of any chalybeate spring, whose waters a person would wish to drink, but cannot conveniently get at.

The salts, tinctures, and other chemical preparations of steel, contain the virtues of that metal as strongly, or much more so, indeed, than the natural, or than these artificial waters; but there are many reasons why the waters, especially the native ones, are to be preferred to them. Both agree in the advantage of a copious quantity of liquid, swallowed with the medicinal matter; by which means, viscid and tenacious humours, that cause the obstructions they are often drank to remove, are much better dissolved than they could be, even by a more powerful medicine with less fluid; and the native ones, in particular, have the advantage of containing the particles of this metal in so remarkably fine a state, that they are even volatile, and not only are suspended in the water, without altering its colour or pellucidity; but on that water's being exposed to the air but a little while, they fly off and leave it vapid and insipid, though before extremely spirited, and strongly tasting of the iron.

They

They are of service in all cases in which chalybeates are proper, and even when there is not convenience of taking these, there is no way of giving chalybeates themselves with so much effect, as by largely diluting them with water.

The mineral waters impregnated with salts are very various, according to the nature of the salts they contain. Some of them are impregnated with a salt of the marine kind; others with a fixed alkaline one of the natrum kind; these last are called nitrous, but very improperly; and others with an alkali and vitriolic acid, which, mixing together, form a salt of the nature of the factitious one invented by Glauber, and named from him. These last are much the most common of all, but their origin is, in general, the least understood.

The waters containing marine salt alone are no other than weak brine springs, the same, in their nature, with those from which we, in many parts of England, prepare salt for the table, only that they have but a very small portion of it. The sea water itself comes under the class of these, but there is a great deal of difference in the taste, qualities, and effects of this, from the waters of such springs. They are impregnated solely with pure rock salt of the sal-gem kind, without any admixture; but the sea water contains, with this salt, another of the volatile alkaline kind, produced by the putrefaction of the bodies of dead fish in it, and always with this a portion of bitumen, to which it owes its bitterness.

Sea water, because of this disagreeable taste, is rarely given internally, though, when people can be prevailed with to take it, great advantages are to be expected from it. It is of great use however in bathing; cutaneous eruptions of almost all kinds are cured by a constant use of it this way for some time; tumors and pains of the limbs are also often cured by it, and we find it continually recommended as the great medicine against the most terrible of all diseases, the bite of a mad dog. It is a common error to suppose that water with salt dissolved in it is the same thing with sea-water. It is said indeed, that it has answered in the external way, by way of bath, in some cases; but those people have been miserably deceived who thought, from the internal use of salt-water some time since brought up among us, that they supplied its place in a pleasanter manner by drinking common water with some sea-salt dissolved in it.

The medicinal waters, naturally impregnated with sal-gem, purge by vellicating the intestines, and promote the discharge of urine; they are also discutient, drying, and astringent. They are recommended in dropical and cachectic cases, and often do great service. They cleanse foul ulcers, externally used, and dispose them to heal, and by a long continued use have been known to do service in paralytic complaints, and to oedematous tumors. There are a great number of these springs in France, and great benefit is received from them. The waters which contain an alkaline salt, and are improperly called nitrous ones, are cathartic and diuretic. It is evident the salt they contain is very different from our nitre, since, when separated from them, as is easily done by evaporation, it is not of the taste of nitre, but acrid and lixivial; and, when thrown on the fire, it does not deflagrate as nitre does. It is a true fixed alkaline salt of the nature of the natrum of the ancients, or sope earth, as it is called, of Persia. It affords the same quadrilateral truncated crystals on a careful evaporation after a second solution, and, like that salt, has all the properties of the fixed alkalies fermenting with acids, turning syrup of violets green, and the like.

The waters impregnated with this salt, of which there are many in France and Germany, are excellent for the attenuating tough and viscid humours, and removing obstructions of the viscera. They are also given in jaundices, in palsies, and in nephritic cases with success. It is however a general rule not to give these kind of diuretics, where the suppression of the urine arises from a stone too large to be voided. For in this case, the afflux of a larger quantity of urine to the passages must be of great hurt, instead of good, to the patient. Externally these waters are used with success in tumors and hard swellings, and in paralytic numbness.

The most common of all the waters impregnated with salt are the purging ones, which contain a salt of the compound kind, easily separable from them by evaporation, and when separated, found to be of the nature of Glauber's salt. Of this kind are many of the purging waters about London, and those of many other parts of the kingdom. Yet, though these waters are of all the mineral kinds the most common, their nature and origin have been the least understood. They have been supposed by many to contain only sea salt, by others a nitrous, and by some, by a wilder guess than any of these, to be impregnated with a shining fossile substance resembling talc, and properly called selenites. There are usually selenitæ of one kind or other met with in the strata of clay, through which they dig to get these springs; and this, having somewhat of the external appearance of a salt, has been supposed to impregnate them; but this is so contrary to reason, that no one acquainted with the mineral kingdom can give any sort of credit to it; the selenitæ are not soluble in water, and, if they were, they must give the water they were received into an astringent, not a cathartic virtue. They are all manifest astringents, and one of them in particular, of the rhomboidal kind, is called by the people of some of our counties, where frequent, staunch, from its known virtue of stopping hæmorrhages.

The salt which impregnates these waters is of a compound kind; it wants a name at present, but is the very same salt with that made by art, and called from its inventor Glauber's salt. On looking into the process of making Glauber's salt, one would not think it, at first sight, the result of a combination likely to be made by nature in the bowels of the earth; yet nothing is more certain than that these waters all contain a salt of the same kind with this of Glauber, and that the same salt is not only found in this state of solution, but even in a solid form in the earth; and that not only in England, but in almost every other part of the world.

The clay pits about London, and many other places, near which there are purging mineral waters, abound with a kind of nodules or masses of clay, of a different colour from that of the stratum, usually paler and yellower; they are commonly of the bigness of a hen's egg or thereabouts, sometimes flat, sometimes roundish, and more usually oblong. They have always something of the pyritic kind in their center, very frequently a regular crustated ferrugineous body, with a great deal of the matter of the common pyrites in some of their crusts; and they are often spangled on the surface with a number of small glittering selenitæ. These nodules, after they have been some time exposed to the air, frequently contain a large quantity of a native salt of this kind; they never have any of it, when first dug up; and many of them afterwards have so little, that it requires some address and management to discover it; but others of them contain so much that it is very evident to the taste, and easily separated into fair crystals; to have them in this state, however, a proper period is to be watched; it does not happen till they have lain a long time exposed to the air, and, soon after they arrive at it, they moulder to pieces and are lost.

Accident discovered the salt to me, says our author, in one of these nodules collected at the lucky period. I had, continues he, thrown it into a basin of water, with no other intent than to separate the little selenites it contained without injuring their figure, when, after a day or two's standing, the sides of the basin were incrustated round with some crystals, whose figure and taste declared them to be the same with Glauber's salts; in examining other of the nodules, some of them were found covered in certain parts with white efflorescences, which were bitter and cold in the mouth, and were evidently the same salt, first separated, and compared with Glauber's salt. A quantity of this salt, afterwards separated from a number of these nodules, formed itself pretty regularly into the true figure of Glauber's salt, and answered all its characters on the strictest examination. It is bitter and cold to the taste like it; it dissolves as readily in cold water as common Glauber's salt, and requires the same quantity of water to dissolve it; and, like that salt, loses

two thirds of its weight in calcination. Its calx mixed with three times its weight of water coagulates it into a sort of ice; it dissolves iron, and precipitates it in a fine reddish crocus, as it dissolves it; it calcines in the air and sun, just as the Glauber's salt does; it easily melts in the same manner on burning charcoal without taking fire, and burns to a saline calx; and it precipitates mercury dissolved in spirit of nitre into a yellow precipitate or turbith. These experiments leave not the least room to doubt its being the very same salt with that procured by chemistry according to Glauber's method; nor is this the only instance, in which such a salt has been found.

The French academicians received from Grenoble in Dauphiny, so long since as the year 1727, a saline earth full of glittering spangles; which, on accurate examination made by Monf. Bolduc, was proved to contain a true Glauber's salt. The mention of spangles in this earth so well agreed with the selenites formed usually in that which contains this salt with us, that it was easy to suspect they were the same. When the hint of a native salt was thus given among the French, they set on foot enquiries after it in other places, and it has accordingly been discovered in some other parts of their dominions; and in Spain, Hungary, and even in Egypt, where M. de Mars found it in the year 1732. In many of these places it does not wait the effects of exposure to the air, in order to form or disclose itself, but is formed, at different depths in the earth, as perfect as on the surface; and in all probability it is in the same manner lodged perfect in the strata in some places with us, though the discovery of it is at present so new that there has been no opportunity to carry the searches farther. In effect, it is to this salt, sometimes pure, sometimes disguised by admixtures of other salts, that most of the purging waters of Europe owe their virtue. In France, there have lately been discovered some waters impregnated with this salt only: in Spain it is found only in water, never in a solid form, or lodged in earth; but, when separated from the waters of the springs that contain it, it is entirely the same with this salt of ours, and of the French, and with the Glauber's salt of the shops. We have the experiments made by M. Bolduc on the salt thus separated from the Spanish waters, and from the sal Glauberi of the shops; to prove that they are absolutely the same, he gives us several processes on metaline subjects with them, and the operation of both is the same in all respects, and is plainly that of a vitriolic acid.

When we examine the process for making the factitious salt of Glauber, we find it is the result of the combination of the vitriolic acid with the alkaline matter which is the basis of common salt; and, when we understand so much of it, it will not be difficult to allow that it is a process that may be performed, and a combination that may be made in the earth. We find that Stahl's weaker acid of sea-salt will give place to the stronger acid of oil of vitriol on mixture, and, yielding up its basis to this new one, there is a new salt produced, and this without any chemical apparatus, or the very assistance of fire; the acid of one salt may then easily combine with the basis of another. The basis of a sea salt is a harsh earth so extremely attenuated as to approach to the nature of an alkaline salt. This earth is in all the fossile muriatic salt scattered throughout the earth, and this fossile salt is present in many places, as may be proved by experiments made with that nice test a solution of silver, where it is not at all suspected, as not being in quantity enough together to be distinguishable to the taste; but, beside this salt, the earth which is in its basis may be also loose and separate in disseminated particles in many earths where we have no idea of it, but where the vitriolic acid finding it out may combine with it, and form a salt like what is here described. That the vitriolic acid abounds in the earth is evident beyond all dispute, and that these do meet and combine is as certain from this salt, which can be the result only of such a combination, as it is from reason that they may.

In the case of our English saline nodules, the manner of their becoming impregnated with this salt shews evidently that the alkaline basis of sea-salt is contained in the clay, and is ready to receive the vitriolic acid, whenever it offers; these nodules contain the matter of the pyrites within them, which, while in the earth, like the pyrites in all other forms, while buried, discloses nothing of its vitriolic acid, and therefore cannot act upon the alkali in the crust; but no sooner has it been exposed to, and penetrated by the air, than vitriol is formed, and its acid mixing with the basis of alkaline matter in the crust affords us this singular salt. As these nodules contain none of this salt till they have lain a while exposed to the air, it is impossible they should impregnate the waters that pass through the strata where they lie, and make them cathartic; but in all probability there is more of this alkaline matter in the strata, which, meeting with the vitriolic acid ready formed in the earth, furnishes the purging salt which is the result of their mixture in abundance, and impregnates with it all the water that passes by.

It is evident, that there does need sea salt for the formation of Glauber's salt; the basis of that salt is sufficient, and is what our new found salt is formed of. Our salt, or that of Glauber, will either of them make a hepar sulphuris with charcoal; and the basis of our salt separated by this process, and examined in the nicest manner, and by the most critical experiments, proves to be entirely the same with that of Glauber's salt, and both the same with the basis of sea salt. Mixed with spirit of nitre, it produces the quadrangular nitre; with spirit of salt it affords a true regenerated sea salt, which is the strongest of all proofs that it is absolutely the same substance that is the basis of sea salt, and mixed with oil of vitriol it produces a true and genuine sea salt again.

There is not in the world a salt more singular in its nature and its effects in mixture than Glauber's salt, or that has more incommunicable properties. The mixture it is liable to, when formed in a state of solution in the purging waters, renders such as is separated from them less fit for the nicer experiments; but that which is separated by solution from these nodules will never fail to answer in every particular to the utmost nicety.

The waters impregnated with this salt purge gently, and without pain or irritation, and are excellent in all disorders arising from a viscid phlegm, which they attenuate and carry off; they restore a decayed appetite by perfectly cleansing the stomach, when oppressed with a load of this phlegm, and are good in all disorders arising from obstructions of the viscera. The sulphureous mineral waters are distinguished from all others by their smell being like that of lime or of sulphur, though very different in degree; many of them also incrust with absolute sulphur the passages through which they run, and the rest, when evaporated to a dryness, always afford a residuum, which proves to be sulphureous on chemical trials, and indeed discovers itself sufficiently and obviously on throwing it on burning coals, for it burns there with a blue flame, and a smell that no body can be mistaken in. The sulphur with which these incrust the passages they run through, is extremely like the finest flour of brimstone; it is of a pale yellow colour, and very sulphureous smell. It is collected on the spot, and is much esteemed, in some places, for medicinal use; but, as to its excellency that way, it is not easy to conceive that it can be greater than that of flour of brimstone truly prepared.

The waters thus impregnated are drank in asthma's, and other diseases of the breast, and in cases of cutaneous foulnesses of all kinds, in which they have great success. They are also used as baths on some occasions, and for trembling contractions, or paralytic numbnesses of the limbs, and for the rickets in children.

The virtues of sulphur may be communicated to water, and it may be made to imitate that of the natural sulphureous springs, by burning and quenching sulphur vivum in it several times; but it becomes a very disagreeable liquor by this means. The mineral waters impregnated only with terrene or earthy particles are of an inferior,

ferior class to all the others; there are several of them in Germany, Italy, and Lorrain; they contain a fine, white, light earth, which is much the same in all of them, and is no other than the *lac lunæ* of the modern authors, or *creta seleneusiaca* of the ancients; this is sustained in such imperceptible particles in them, as they came out of the spring, that they are perfectly clear; but they do not carry it far, but deposit it about the bottom and sides of their channels, as they run off.

They are drank against hæmorrhages, habitual diarrhoea's, dysenteries, and diabetes, and in all cases where a soft alkaline absorbent and astringent can be of use; but, in general, the taking the earth they deposit, or any other soft alkaline astringent earth in its place, would answer the same purpose, and in many of the cases would succeed better alone than with that load of water it is joined with in this state.

Uses of WATER in vegetation.—Water is absolutely necessary to the growth of vegetables, and experience hath long evinced the great advantages arising from the overflowing of pastures. It is however but of late years that this very profitable improvement is become pretty general in England; nor is it, as Mr. Worlidge observes, yet carried to near the perfection it might be advanced to, if the following obstructions were removed.

1. The several interests that are in lands bordering on rivers, hinder very much this improvement, because the water cannot be brought over several quantities of land so circumstanced, but through the ground of ignorant and cross neighbours, who will not consent thereunto, though for their own advantage also, under unreasonable terms; and some will not at all. Others, again, are not, by law, capacitated for such consent.

2. A great and pernicious impediment to this improvement is the mills that stand on many fruitful streams; prohibiting the laborious and ingenious husbandman to receive the benefit and advantage of such streams and rivers, which carry in their bowels much wealth into the ocean, while the mills themselves yield not a tenth of the profit to the owners, that they hinder to their neighbours, and their work may be as well performed by the wind, as by the water.

3. Another grand impediment is the ignorance of the countrymen, who are commonly possessed with a foolish opinion, that the water leaves all its fatness on the ground it first flows over, and therefore will not benefit the next; which is most untrue; for meadows have been seen successively drowned with the same water, to almost an equal improvement for many miles together. It is true, the water leaves behind it a great part of the fatness which it hath washed from the hills and high-ways in the time of great rains: but we find by daily experience, that meadows are fertilized by overflowing, as well in clear and dry weather, as in rainy, and that to a very considerable degree. The clearest and most transparent streams will improve even ordinary lands, so much as to render them very fertile meadows.

4. From a greedy and covetous principle, the grass is suffered to stand so long on the watered meadows, that it becomes much discoloured, grows haulmy, and is neither so toothsome nor so wholesome, as that of unwatered meadows.

5. The former of these impediments might easily be removed by a law, which would be of very great advantage to the kingdom in general. The latter can be remedied only by the example of such industrious and worthy persons as understand better things: the generality of the world being rather induced to an ingenious and profitable enterprize by example, than by precept: although some are so sordid and self-willed, that neither apparent demonstration, nor any convincing argument whatsoever, can divert them from their bias of ill husbandry.

The industrious Swifts, sensibly attentive to every means of benefiting their deservedly cherished country, have thought this branch of husbandry of sufficient importance to propose it for the first premium offered by their truly laudable Society at Berne, for the year 1760: and to them we are indebted to the dissertations produced thereby, for several of the following remarks.

Water not only acts as a vehicle to the nourishment of plants, but also carries with it many particles which enrich the soil; especially after heavy rains. It then deposits a fertilizing sediment, which turns the mould to a blackish colour. The common saying, that watering makes the stones disappear, is true; not so much from their sinking into the earth, as from their being covered by the new supply of mould brought by the slimy muddy water, particularly after great rains. Watering likewise promotes the putrefaction of every vegetable and animal substance found in the earth, and thereby contributes greatly to meliorate the soil underneath the sward.

Plants which grow on dry pastures contain richer and more nourishing juices, than those which grow in moist places. Care should therefore be taken, that the quantity of moisture brought upon the pasture, be only such as shall give vigour to the plants, without over-charging their vessels. In order to do this, every part of the pasture should be watered equally, and as little water as possible should be suffered to go where the land is naturally moist.

Extreme heat should also be avoided in watering; because heat draws the moisture too hastily up into the plant, which is thereby filled with a watery juice, and rendered of so tender a texture, as easily to be killed afterwards by drought or cold.

If the spring proves dry, pastures may be watered as soon as the frosty season is over; and this may be continued till the grass begins to shoot. But if the winter has been severe, and the earth remains moist, no current of water should be admitted, till the earth loosened by the frost is settled, and the surface become pretty dry: for even the gentlest stream would carry off the fine mould loosened by the frost. After that the grass has begun to shoot, and the weather is become mild, the water should be administered more sparingly; that is to say, in such proportion only, as just to push the grass gently on, till it has made such a covering as can shelter the earth from the too great power of drying winds, or of a scorching sun. Watering should afterwards be used with great caution, and only in case of extreme drought; nor even then, unless the water be perfectly clear and sweet, lest it should foul the grass, or give it a bad taste. If it be admitted sparingly before the hay is cut, it will make the grass stand the better to the scythe.

For a little time after the hay is made, the water should be admitted only in the night: because the weather then generally is very warm; for it is observed, that rain which falls with a hot sun, or a hot sun that comes on a heavy dew, is prejudicial to plants. Watering, under the same circumstances, will have the same effect, to prevent which the prudent husbandman will let in his water only in the evening, and will withdraw it again before the sun gets up. It is continued at this season only till the grass begins to shoot vigorously; and in case of very great drought it may be repeated, but very sparingly.

If a second crop of hay is made, the water may be used more freely; as the weather is then become cooler, and the earth is generally very dry. This flooding will bring up a plentiful after-math. If the second crop of grass is fed off, the watering should be renewed in the same manner: only care should be taken not to suffer cattle to feed on the ground while the water is upon it, because their poaching would destroy the roots of much of the grass, and leave the surface uneven, which should be avoided in a pasture.

The latter end of autumn is the season in which watering is the longest continued: and considering the dryness and parched state of the earth at that time, this practice seems rational: for the water then, not only supplies the moisture wanted in the earth, but it dissolves every substance soluble in water, and thereby converts to an additional manure, what might otherwise have remained long in its original state. Care should, however, be taken, to drain off the water before the season of strong frosts is expected; because frost is observed to destroy all kinds of vegetables much more when the plants are full of sap, than when they are in a dryer state. We may

may easily comprehend that it must have this effect, when we consider with what force it breaks every vessel containing water exposed so as to be frozen: for frost dilates all fluids to such a degree, that the vessels in which they are must be broken thereby. Hence it is that succulent plants soon become a putrid mass after a hard frost: and thus it is that the strongest trees are sometimes burst with a loud report.

When the water is brought to the desired height, the main channel should be cut, with such a descent as only just to keep the water in a gentle motion. That channel should be made in the highest part of the pasture, and proportioned to the quantity of water necessary to be introduced. If a hollow intervenes between the place at which the water is brought into the field, and another rising ground in that field; it will be worth the farmer's while to convey it across that hollow, by pipes made of wood, or any other substance, laid either horizontally over that hollow, or underneath it. The motion of the water in this horizontal channel should be different, according to the quality of the ground. If it is a strong earth, the channel may be cut nearly horizontally: but if it is a light loose soil, a quicker current should be given to the water, in proportion to the degree of lightness of the earth; or great part of the water will otherwise be lost, by sinking into it. In a light soil of this kind, it may be proper to line this main channel with brick or stone, well cemented with lime, to hinder the water from escaping through the crevices; or at least to cover it with clay well rammed. As to the degree of descent most proper for the main channel, in order to give a current to the water, M. Bertrand, to whom we owe one of the ingenious dissertations on this subject in the Memoirs of the Berne Society, observes, that Vitruvius required six inches in an hundred feet, which is a great deal too much: but that the moderns, who have made the most exact experiments in this respect, are satisfied with two inches in six hundred feet, when they cannot have more, and recommend particularly the avoiding of all sharp angles in the winding of the channel, and the making of its bottom quite smooth and even. He adds, that this is nearly the declivity of the aqueduct of Rocquancourt, by which the water is conveyed to Versailles; the distance there being three thousand four hundred yards, and the slope, in all, only three feet.

The main channel should be of breadth, rather than depth, sufficient to receive all the water that is intended to be conveyed through it, and that breadth should lessen gradually as the water is carried off in lesser channels, in order that the water may press into those smaller ducts, which are to issue all along from the chief. The lesser channels should be as shallow, and as numerous, as can be: for the more equally the water is distributed over the grass, the greater will be the improvement. They should be made particularly wherever the water collects itself into a stream: for though cutting so much turf may seem to waste a great deal of land, yet it proves not so in the end; because the quicker the water runs over the grass, the more it benefits the pasture.

To keep the channels in repair, they should be frequently cleaned, especially after every cutting of the hay. The slime then taken out of them should be spread upon the pasture, and the next growth of the grass will be greatly improved thereby. Care should also be taken to have drains to carry off the water, so that none of it may stagnate upon the land.

The best way of watering a flat meadow, which is usually surrounded with a ditch, is to stop the out-let of the ditch, and, by bringing in a quantity of water, to overflow the whole meadow, for such time as shall be judged necessary to moisten the earth sufficiently; but the water should not be continued upon it so long as to wither the grass. If this can be done in a rainy season, it will be so much the better; because the water will then be loaded with the enriching mud and slime washed down from the higher grounds.

The first heavy rains which fall in the latter end of the autumn, and which carry with them the rich particles of putrified animals and plants, are thought to be more fertilizing than at any other season of the year, and

are therefore brought into the pasture, as often as the absence of the cattle fed on them will permit.

The next best to rain, is clear and sweet spring water, flowing from a copious source. Here it is generally objected, that spring water is hard, and therefore not fit for the nourishment of plants. But Dr. Home, who judges otherwise, expresses himself thus on this very occasion. "Is not hard water more nourishing for vegetables than soft water? I imagine that the salt of vegetables enters their vessels in such a form as hath the salt which is found in hard waters. The salt of hard waters seems likewise to be of the nitrous kind, of which the nourishment of plants is also supposed to be. This query thwarts the general opinion; for no gardener will make use of hard water, if he can avoid it. I watered some plants with it, and thought that they grew better than those which were watered with soft water."

This is confirmed by an ingenious correspondent of the Berne Society, who made several experiments on the qualities of different waters, and found that their greater or less hardness made very little difference in their effects, when used for watering of pastures. The water of an excellent spring, which, upon trial, was found to be hard, fertilized greatly the pasture upon which it was let in.

Spring water may be used later in the winter, than any other, because, being warm, a mild frost will not freeze it, even when expanded on the pasture. It should however be turned off soon enough to let the earth become a little dry before severe frosts set in. It may likewise be used earlier in the spring, than other waters, and to better advantage, by reason of the warmth which it communicates to the ground where it flows: and it becomes extremely proper in the summer, because it cools during the night, the only time for watering at that season, the heated soil, and grass scorched by the power of the sun.

The equal warmth of spring water, is what renders it peculiarly useful for watering pastures. The last quoted correspondent of the Berne Society tried its heat, in Switzerland, on the twenty-sixth of May, when the earth had been very little warmed by the sun, after a long winter's cold. He then found M. de Reaumur's thermometer, placed in the spring of water, stand at eight degrees and a half, equal to forty-seven and a half of Fahrenheit's, above the freezing point. On the fifth of July, in the evening, when the heat of the air was very great, Reaumur's thermometer, again placed in the spring, stood at nine degrees and a quarter, equal to forty-nine of Fahrenheit. He afterwards tried whether the warmth of the spring was considerably increased towards the end of the summer, when the earth was extremely heated: but even then, Reaumur's thermometer scarcely reached ten degrees, equal to about fifty of Fahrenheit's. By this we see, that springs which yield a full and constant stream vary very little in their degrees of warmth.

For the same reason it also is, that a perpetual verdure reigns around such springs, even during the hardest frost; and if their water could be preserved from freezing when spread over a field during the winter, it would be right to let them in upon pastures in that season: but as they soon lose their heat when dispersed over the grass, this is by no means advisable.

Experience has taught the inhabitants of the Alps, and the same will hold equally true in all mountainous countries, that it is not advisable to water pastures with the floods which arise from melted snow, or with the water of rivers fed thereby. One reason which seems to render the water that descends from mountains perpetually covered with snow the less useful for watering pastures, is, that as all vegetation is at a stand in such places, no vegetable matter can be mixed with this water; and it therefore cannot communicate the fertility which arises from waters fraught with those rich substances.

We are frequently told of correcting the crudity of water, by making it turn a wheel, or putting it otherwise into violent motion; but we know not what good effect this can have.

What

What are commonly called barren springs, are sometimes corrected by mixing dung with their water in ponds made higher than the pasture intended to be watered. Yet this, though an old custom, is liable to some objections; one of which, in particular, is that the water will deposit its richness on the first part of the pasture over which it flows, and therefore improve the grass very unequally. But if dung has this effect, it will answer equally well, if it be spread upon the land. Care should, indeed, be taken, that the current of the water be very slow over a pasture newly dunged; because the fertilizing particles of the dung may otherwise be carried off by the stream, before they can have had time to penetrate into the earth.

When dung, marl, or lime, is laid on a pasture which has a considerable descent, the best way is to lay a larger proportion on the higher parts; because the common rain water will wash some of their richer particles down to the lower.

As clayey soils retain water, and by that means chill the plants growing on them, they are the least fit for watering of any. If the water continues on them, they become poachy; and when dried again, they gape, and become so hard that no plant can pierce them. Some sensible farmers have likewise observed, that their clayey lands have always yielded less grass in wet years, than when the season has been dry; which is a manifest proof that a soil of this kind does not admit of watering, unless it be a little, in case its surface is become hard after the hay has been taken off, or when the grass is short. Such lands are fitter for arable, if their situation permits it.

Hazel earth, which is a loam mixed with gravel, and of a clayey nature, is the strongest soil that can be watered, with propriety: and that this has been surprisingly benefited thereby, is evident from several instances given in the Memoirs of the Berne society, even of large tracts of such ground that have been vastly improved by this means: but we shall mention here only the following.

In the summer of 1758, part of the pasture ground belonging to a farmer in Switzerland was so entirely covered with stones and gravel, by the sudden overflowing of a stream, that it appeared like a bank of sand. As the removing of this quantity of stones and gravel would have cost a great deal of labour and expence, the owner of the land carried off only the largest stones, and threw over the gravel a reddish earth taken from a neighbouring hill; but so thinly spread, as only to fill the interstices between the pebbles, without entirely covering them. He then sowed this spot with hay-seeds, and let in upon it the waters of an adjacent spring and a neighbouring rivulet. These waters were let in sparingly at first, till the grass began to appear, and after that they were flowed more abundantly. The consequence of this prudent conduct was, that the grass thus raised bore cutting once the first year, and after having been mowed twice in the second, promised an excellent after-math at the time when this account was written, which was in the beginning of the autumn of that second year. The very first year's crop grew so prodigiously, that the grass was lodged, even though the pebbles were then felt under foot, if one trod upon it.

Methods of conveying away WATER, when it abounds too much and hinders vegetation.—Before we consider what methods are most proper for conveying away water, it is necessary to inquire what are the things that occasion our being troubled with too much of it in our fields. For if the causes of the disease are known, it will be the more easy to apply the remedy.

Sometimes land is wet from its situation; is exposed to overflowings from higher ground, and has no proper descent to allow the water to run off. When a great quantity of rain falls, it soon makes its way from the heights into the hollows, and there lodges, till it is exhaled.

Sometimes the bottom of land is of such a nature, as to force out in springs, the water that runs below the surface. Water runs in channels below ground. Sometimes it springs out, because these channels, in which it

runs, reach the surface; and sometimes, because it meets with an interruption in its course, which makes it force its way upward, and break out. When water falls upon land that easily admits it, it makes its way downward, till it is resisted by a bed of till, clay, or rock. If this bed has a declivity, as is commonly the case, the water falls along the declivity. If in any place this bed reaches the surface, or if the water meets with any interruption, there it breaks out; or if the ground rises, and the bed rises along with it, then the water breaks out in the hollow.

Sometimes the wetness of land is occasioned by the season, or climate, in which the rain is violent, and so frequent, that no time is allowed the land to dry. And

Sometimes all these things may concur to render land wet.

The wetness of land from its situation may be prevented. The water, as it falls from the higher ground, may be received into drains, and, by these drains, conveyed away; and thus prevented from overflowing the land below. For although the land may be so low situated, as to render it difficult to convey away the water that falls upon it; yet the water may be intercepted, in running from the higher ground, before it reaches the hollow by a drain, at a place where there may be a sufficient fall. If the higher ground is in tillage, the ridges and drains of it may be placed in such a manner, as to prevent the water from coming down from it with violence; or the water may be directed, in its course, to channels where it can do little harm.

The wetness of land from the nature of its bottom, may likewise, in some measure, be prevented by drains. Land wet from the breaking out of springs, is generally upon a declivity. If the water runs near the surface, before it breaks out, it may be intercepted by a drain drawn across the declivity, a little above the place where it first makes its appearance. And, if the channel lies deep, it may be prevented from running over the land below by a drain, drawn across exactly where it springs up. In some cases, it may be known, whether the channel of the water is near the surface, or lies deep. If the land is dry immediately above the place where the water springs out, it is an evidence that the channel of the water lies deep: if, on the contrary, the land is wet, even at some distance above the place where the water springs out, it is a presumption, that the channel of the water is near the surface. It would be a certain evidence of it, if there were no more springs but one. But if there are several springs, arising from water running in different channels, the land above the principal spring may be wet, not because the channel of the water of this spring is near the surface, but by the breaking out of other lesser springs, the channels of whose waters reach the surface, before that of the waters of the larger spring.

The wetness of land, arising from the climate or season, is not to be prevented in the same manner, as that which arises from the other two causes mentioned. When land is wet, either from the over-flowings of higher ground, or from springs, the water, by drains, may be intercepted; and thus prevented from doing harm. But when the wetness arises from the climate, or a season in which there is too much rain, as is often the case, it cannot be made dry by intercepting the water. In this case, we can only remove obstructions, and thereby allow it, as quickly as possible, to run away. Casting drains in places of the field where the water is in danger of stagnating, will be of some use; but this cannot answer the end; for thereby no more is done than conveying away the water, that would stagnate in the hollow; while nothing is done to convey it from the rest of the field. And therefore, to drain land in this situation, it is necessary to lay it up in ridges properly placed, and to cut small drains across the ridges, where necessary, communicating with each other, and with the furrows. For, by this method, all the furrows betwixt the ridges become drains. The water, as it falls upon the ridge, immediately makes its way to the furrows, and along them where there is any descent; and, if it is stopped in any of them by the ground rising, is conveyed by the drains

Fig. 1.

drains across the ridges, into some other furrow, where there is a descent, along which it makes its way off of the field.

Drains have been mentioned, as necessary for preventing or removing the wetness of land, from whatever cause it proceeds. There are two kinds of them used: open drains, and hollow drains. Hollow drains have some peculiar advantages. Being covered with earth, no land is lost, and they are no impediments in ploughing. On these accounts, they are preferable, in some cases, to open drains. But these advantages have made some persons use them very improperly, and when they could be of very little use. In every case, open drains will answer the purpose of draining; and therefore are always to be used when it is uncertain whether hollow drains will answer the purpose. Open drains only are proper for intercepting the overflowings of water from higher ground, and for conveying away water that falls in rain. The reason why hollow drains will not answer these purposes, is obvious. The water being on the surface, cannot find its way to them: if they are on a declivity, the water will run over them, as it does over any other part of the field: and, if they are in a hollow, the water will stagnate even above them, and will be mostly exhaled before any quantity of it reaches them. But hollow drains may be used for intercepting the water of springs. Because nothing more is required in this case, than to continue the channels of the water below ground to a proper place, where its breaking out can do no harm: for which purpose hollow drains are very proper.

Before we leave this article, it will not be improper to observe, that land is sometimes wet from the nature of the soil.

There are two kinds of soil, that are much exposed to be damaged by water. The soil in which there is a great mixture of clay; and the soil in which there is a great mixture of moss. Experience shows, that both these kinds of soil take much longer time to dry than others, that have received as much water, and are in the same situation.

We shall best know how to render these soils dry, by inquiring into the cause of their wetness.

It is observed, that clay is a heavy body, that it does not easily receive water, but that it retains a large quantity, and will not easily part with it, when once received. It would seem, then, that clay has many pores, but that its pores are small. Having many pores, it is capable of containing a large quantity of water; but, its pores being small, the water does not easily enter into it, or pass through it.

It is observed, that moss has still worse qualities than clay; for it not only retains a large quantity of water, but also easily admits it. It would seem, then, that its pores are large; but that it has a strong absorbent quality, or contains a great quantity of undissolved oil. The largeness of its pores easily admits water, and its absorbent quality, or the undissolved oil, which it contains, prevents the passage of the water through it.

It is obvious, that laying up such lands in ridges, and casting drains in proper places, though of some use, yet will not effectually remove the water; as the soil, from its nature, retains too large a quantity, and will not give it a passage into the furrows or drains, though there is a sufficient descent. To drain such land, it is necessary therefore, by culture, to change the nature of it, and, in some measure, destroy its power of retaining water.

As the pores of clay are so small, that water cannot find an easy passage through it; to drain this kind of soil, its pores must be enlarged: frequent stirring, and the application of such manures as raise a fermentation, seem to be very proper for this purpose. These operations open the pores, render the soil free and open, and thereby the water finds a more easy passage through it. The manures particularly, that are long in dissolving, are the most proper; for, till they are wholly dissolved, they keep the soil continually open.

Some persons have observed, that clay has this bad quality; though reduced to powder, yet, when mixed

with water, becomes as solid again as ever. As this is the case, though manures may help to make it part with the water, as they open the soil by fermentation, both in the time of the rain and after it has fallen, yet frequent ploughings can do but little service; on the contrary, by opening the soil, make it receive the water more easily. It is therefore recommended to all persons, who have this kind of soil to deal with, as a matter of the greatest importance, to lay up the land, before the rainy season comes on, in such a manner, as allows the water the most easy passage, and exposes it best to the influence of the winds. For thereby a great quantity will run off, and be exhaled, which otherwise would sink into the land.

As moss has its pores too large, and has an absorbent quality, or a large quantity of undissolved oils, which prevents the passage of the water thro' it; to drain this kind of soil, it is necessary to lessen its pores, render it more compact and firm, and, if possible, destroy its quality of retaining water. Frequent stirring, as already mentioned in the case of clay, and the application of such manures as raise a fermentation, will lessen its pores, and render it more firm and solid; and thereby prevent it from receiving so large a quantity of water. And the application of such manures as tend to make the moss putrefy, and to dissolve its oils, will, in some measure, destroy its power of retaining water, and thereby allow it a more easy passage.

Sometimes it is observed that land is wet, though there is in it a great mixture of sand or gravel. These are kinds of soil which allow the water an easy passage, and are commonly very dry. When they are wet, this must be owing to the nature of the bottom. Clay, till, or something that does not easily admit water, must lie near the surface. When this is the case, the land, tho' on a declivity, will be wet after violent rain. The water is easily admitted by the sand or gravel on the surface; it is resisted by the clay, or till, in the bottom; and, tho' it descends along these, yet the absorbent quality of the soil, and the other interruptions which the water meets with, render its motion very slow. When land in this situation is on a plain, the qualities of the sand and gravel can be of little use to render it dry. It is needless to propose drains in either of these cases. The method of ploughing is the only thing that can be of service. Forming the ridges in such a manner as to make many furrows, and placing them in such a manner, as to make the furrows intercept the water, seems to be the proper way of draining this kind of land, when on a declivity; and the forming the ridges in such a manner, as best to expose the soil to the influence of the air and winds, seems to be the proper way of draining it, when on a plain.

But when the land is above the level of the adjacent water, recourse must be had to some engine to raise it to a proper height, in order to overflow it; though this will be attended with a very considerable expence, especially at first.

The oldest instrument used for this purpose is known by the name of Archimedes's water screw, and is thus described by Mr. Emerson.

C p D (plate CXXXVII. fig. 1.) is a cylinder which turns upon the axis C D. About this cylinder there is twisted a pipe, or rather several pipes, *no, pq*, running spiral wise from end to end. This cylinder is placed higher at one end, D, than at the other; and its use is to screw up the water from the lower end to the higher. A B is a river running in the direction A B; *a, b, c, d*, are several floats fixed to the cylinder. E F is the surface of the water. As the cylinder stands in an inclined position, the upper floats *a, b*, are set out of the water, and the under ones *c, d* within it; so that the water acts only upon the under ones *c, d*, and turn about the cylinder in the order *a, b, c, d*. By this motion, the water taken into the spiral tubes at the low end is, by the revolution of the cylinder, conveyed through these pipes, and discharged at the top into the vessel G. If A B is a standing water, there is no occasion for the floats *a, b, c, d*; and then the cylinder is to be turned by the handle at D. Instead of

the pipe, a spiral channel may be cut round the cylinder, and covered close with plates of lead. The closer these spiral tubes are, the more water is raised: but it requires more force. Also the more the cylinder leans, the more water it carries; but to a less height.

Where a considerable quantity of water is to be raised, a greater force is requisite, than can be applied to such a handle. Her royal highness the princess dowager of Wales has caused an instrument of this kind to be erected at Kew, by the ingenious Mr. Smeaton, and by means thereof a sufficient quantity of water is supplied, for all the ponds, and other uses, in that elegant and extensive garden: but it is there worked by horses.

The most common engine for raising water is the Persian wheel, of which Mr. Worlidge gives the following description.

This wheel is made much after the manner of that of an under-shot mill, viz. with a double ring, into which are let two pins, on which the floats are fastened. These floats are made hollow; the half that is the most remote from the wheel, holds the water which is taken in at the open place, above the middle of the back of the float, and as the wheel goes round, and the float laden with water rises, so the water, by degrees, tends towards that part of the float which is next the wheel; and as the float surmounts the cistern or receiver, the water empties itself into it, every float succeeding one another, and emptying themselves into the receiver: so that if one float contain a gallon of water, and there be thirty floats on the wheel, at one motion round it delivers thirty gallons of water into the cistern. Such a wheel will be about fifteen foot diameter, the floats at eighteen inches distance, and will deliver the water at eleven or twelve foot above the level of your stream, and will go four times round in one minute, and carry up about one hundred and twenty hogsheads of water in an hour, with twelve or eighteen inches penning or stopping of but an ordinary current of water, which will water very well thirty or forty acres of land: for if your land be cold and clayey, too much water does it hurt; and if it be light, warm, or sandy, a little water does it much good. It is also to be observed, that this motion is constant, and will last many years without repair, so that it stand not still, for one side to dry and wax lighter than the other: also observe, that the slower it moves, the better it delivers the water.

Fig. 2. represents the view of this wheel; *a, a, a, a*, signify the wheel; *b*, the cistern that receives the water; *c, c*, the trough standing on tressels, that conveys the water from the cistern to the place you desire; *d*, the hatch, or pen-stock that bays up the water to a reasonable height, under which the water drives the wheel; *e*, *fig. 3*, one of the floats presented open to your eye, apart from the wheel; *f*, the place that is to receive the water; *g*, the open place out of which the water issues; *h, h*, the two pins or ledges riveted on to the fore side of the float, and wherewith you are to fix the float to the two rings of the wheel.

These, or such like wheels, are much used in Spain, Italy, and France, and are esteemed the most easy and advantageous way of raising water in great quantity, to any height within the diameter of the wheel, where there is any current of water, to continue it in motion, which a small stream will do.

How many acres of land lie on the declining sides of hills, by the sides of rivers, in many places where the water cannot be brought unto it by any ordinary way? yet by this wheel placed in the river, may the land be continually watered, so far as is under the level of the water when raised.

Instead of raising the water by means of the hollow floats placed around the outer circumference of the rim of the wheel, as here described; M. Belidor proposes, several wheels of this kind, to raise it in buckets placed at equal distances upon the side of the rim of the wheel, and suspended by a pin, upon which they play, as at *A*, *fig. 4*. When by the rotation of the wheel, one of these buckets comes to *B*, which is the summit of the wheel, the upright piece *D*, which is fastened to the side of the

trough *C*, turns that bucket upon its side, and thereby makes it empty itself into the trough *C*, from whence the water is discharged into a receiver at *E*. — As these buckets keep full of water till they are carried up to the top of the wheel, where they are turned over, a much greater quantity of water may, undoubtedly, be raised by them, than can be by the floats of the Persian wheel, from which much must be spilled as it is carrying up. The size of these buckets should be adapted to the force of the current of the water which they are to take up.

Another wheel for raising water, tho' not to so great a height, is represented in *fig. 5*. This engine was first invented by M. de la Faye of the Royal Academy of Sciences at Paris, and is now used with great success by the honourable Mr. Hamilton, at his seat at Pain's-hill in Surry, where that gentleman has shewn how far a barren spot may not only be rendered useful but even an ornament to the adjacent country.

This machine consists of a wheel whose size is adapted to the height to which it is intended to raise the water. A perspective view of this machine is represented *fig. 5*, and its internal parts *fig. 6*. The wheel turns upon its axis at *A*, and has several curved pipes, *B, C, D, E*, fixed to it, as represented in the figures. The mouth of each pipe ascends as the wheel is turned round by the stream, in the direction indicated by an arrow, and the water descends from *C* towards *F*, till it reaches the hollow axis, *A, A*, from the opening at the end of which it is discharged into the trough *G*, and thence conducted by troughs, as *H*, or other channels, to whatever place it may be wanted.

But if there be a necessity to raise the water higher than the axis of the wheel, we would recommend an ingenious machine, used for above twenty years at Zurich, for supplying a large dye-house there with water from the Limmat, and of which a description in the German language appeared in the third volume of the Zurich Acts, from whence the following account is translated.

The wheel itself differs little in appearance from other water-wheels. Its diameter, exclusive of the ladle-boards, is not quite three feet. It is coated all over with tin plates, and forms a short cylinder, or rather drum, of the above diameter, and one foot thick. On its periphery the ladle-boards are fixed, as in other under-shot water-wheels, and by means of which it is put in motion by the stream. It turns on a hollow axis, like the last machine, of proportional thickness and length, and has one of its flat sides applied against a projection, or ledge, made round the axis, to which it is pressed close, and held fast by a wedge driven through the axis at the other side. That part of the axis which passes through the wheel is square, that the wheel may not slip, or be able to turn, without turning the axis with it: the remaining part of it is round. The wheel is hung in the water to about one third of its height, and supported in a moveable frame, so that it can be lowered, raised, or even taken out of the water at pleasure. In the periphery of the wheel are holes, by which the water enters. The axis turns as usual, on two pivots, one of which is of brass, considerably larger than the other, and hollow from end to end, communicating with the canal in the axis. The hollow pivot, which may be considered as a brass pipe, has its end fitted close to a leaden pipe, in which it turns. The leaden pipe, by a double bending, is confined to the wall of the dye-house, where it is bent perpendicularly upwards, and rises along the wall to the height of ten feet above the axis; it is there bent again under the eaves, and continued into the dye-house itself.

The singular and remarkable operation of this little wheel depends solely on its internal structure. The water entering at the circumference of the wheel, runs in a square spiral canal, which passes round the wheel, and consists of a number of circumvolutions, within one another, like the spring of a watch, till at length it comes into the axis. A necessary condition here is, that each of the inner-circumvolutions be of the same magnitude with regard to their content, as the outer one; or that

that the width of the spiral canal be gradually enlarged in each circumvolution, in proportion as the diameter diminishes; that is, the bore of each of the inner spirals must be to the bore of the outer one, as the diameter of the latter is to the diameter of the former.

The wheel thus furnished with its spiral canal, is to be hung so deep in the river, that half a spiral, at least, may, in each revolution, be filled with water. To keep it in this state it would be necessary to immerse it to the axis, or further: but as its motion, at such a depth, would be extremely slow, a kind of scoop is made at the outer opening of the spiral pipe, which takes up so much water at once, as is sufficient to fill the due proportion of the outermost spiral in one revolution. One half of the outer spiral being thus filled with water, the other half remains filled with air: as the wheel turns, the water and air pass into the second spiral, then into the third, fourth, and so on, till a sufficient number of turns brings the water and air to the axis, from whence they pass into the upright pipe, as already mentioned: thus the entrance and discharge of water continue without intermission, so long as the wheel is kept in motion. When the wheel scoops up just the proper quantity of water, and turns with due velocity, the water may be forced up in the perpendicular pipe to a height equal to the sum of the diameters of all the circumvolutions of the spiral canal.

If we consider the operation of this machine, we shall easily see the necessity of the inner circumvolutions being made to widen in the proportion above mentioned; and that, without this condition, the water passing from the large outer spiral, would be crowded and retarded in the inner, and in great part forced back.

It is also obvious that just half of one of the spirals must be filled with water at each revolution; for if less be taken in, there will be a diminution in the quantity delivered, and if more, it will be pressed too much together, and its quantity also diminished.

The velocity with which the wheel moves, or the number of revolutions it makes in a given time, is another essential point in regard to the quantity of water, and may considerably influence the quantity of water necessary to be raised. When this is known, and the height determined, it will be easy to construct a wheel in such a manner, as to answer the purpose intended.

We shall conclude our account of this ingenious contrivance, with the following directions for constructing it. The two flat sides of the wheel should be made of two strong circular pieces of good oak, the inner sides of which must be planed as smooth as possible, and fitted to one another; and to keep them from bending or warping, secured by pieces on the outside. The plan of the spiral lines is represented in *fig. 7*. These spiral lines being marked out on the wood, a groove must be cut about a quarter of an inch deep, in order to make a channel for the partition, which must be formed of a thin piece of copper. The channel being filled somewhat more than half with good cement that will bear water, the piece of copper must be set in regularly, care being taken to keep the cement warm, or previously to heat the metal. The scoop also, which at every revolution of the wheel takes up a proper quantity of water from the wheel, may be made of the same metalline plate. The piece of copper for forming the partition must be cut at first exactly straight, and of an equal breadth throughout. This work being finished, the wheel must be put on the axis as far as the ledge made for it to rest against, and cemented. The second piece of wood requires little preparation: some cement must be spread all over it, and the whole surface covered with a thick piece of woollen cloth, which must also be done over with cement on both sides: while the whole continues warm, it must be put on the axis, and pressed close to the other part of the wheel, so as to cover the as yet open side of the spirals. The two parts are held firm together, by means of a wedge or key passing through the axis, and a proper number of screws, placed round the circumference: these screws are strong iron pins, somewhat longer than the wheel is thick, and a nut, when they are

placed through the wheel, is screwed on the other. Thus the inside of the wheel, or drum is finished. The disposition of the ladle-boards, the shape of the axis, and the structure of the frame by which the machine is supported, will be partly understood from what has been already said, and more fully from *fig. 8*.

It has been already observed, that the wheel in the Limmat is covered with tin plates; but this is of little or no consequence. It is however adviseable not to have one large opening, for the entrance of the water, but either a perforated plate, or a wire-grating nailed before it, in order to prevent weeds, or any other filth from passing into the spiral tube, and preventing, if not wholly stopping, the course of the water.

The frame or scaffold in which the wheel hangs, and the means of raising or lowering it in the river, without disturbing the course of the water in the machine, deserves particular notice. It is plain from *fig. 6*, that the wheel rests on two arms, which, for the greater security, are bound together by cross-pieces. At the fore-end they are both suspended by iron chains, which pass over a roller so as to be wound off or on; on the other end they move on two strong joints or hinges. The communication of the leaden pipe with the brass one, or hollow pivot, at the end of the axis, is drawn on a larger scale, in *fig. 9*. This pipe is bent close by the pin, to a right angle, and goes horizontally along one of the arms of the frame as far as the hinge, (see *fig. 10*.) where it is again bent to a right angle, opposite to the dye-house, and communicates in the same manner as the hollow pivot of the axis, with another horizontal pipe, in which it moves round freely, without any impediment to the passage of the water, in raising or lowering the wheel. This large pipe passes under a stage built along the wall of the dye-house, and thence up the wall, where it distributes the water in the manner represented in the figure.

But though water is so necessary to the growth of plants, yet in lands that abound with it, there is a necessity for conveying it away, the best methods for doing which the reader will find under the articles BOG, FEN, &c.

WATER, in medicine, pharmacy, &c. called also artificial and medicated waters, are a kind of liquors procured or prepared by art from divers bodies, principally of the vegetable tribe, having various properties, and serving for various purposes. These waters are either simple, or compound; simple waters are those procured from some one vegetable body, the intention of which is to draw out the virtues of the herb, seed, flower, root, or the like, so as it may be more conveniently given in that form than any other. The means whereby this separation is effected, are either evaporation, infusion, decoction, or distillation.

The simple waters of chief virtue are the following ones, viz. dill water, angelica-water, mint-water, rosemary-water, orange-flower-water, black-cherry-water, parsley-water, camomile water, penny-royal-water, fennel-water, damask rose-water, hyssop-water, rue-water, juniper-water, elder-water, lovage-water, carminative-water, &c. for the virtues of each whereof we refer the reader to those ascribed to the several plants, or other bodies from whence the water is procured, which may be found under their proper heads in the course of this work.

Compound-waters, or those wherein several ingredients are used, are very numerous, and make a large article in commerce; some prepared by the apothecaries, according to the dispensatory prescripts, for medicinal uses; others by the distillers, to be drank by way of dram; and others by the perfumers, &c. They are distinguished by different epithets, &c. in respect either of the specific virtues of the waters, or the parts of the body for the cure whereof they are intended, or the diseases they are good against, or the ingredients they are compounded of, or their different uses, &c.

The most considerable among the class of compound-waters, are alexipharmic or alexiterial waters, such as treacle-water, plague-water, milk-water, poppy-water, &c.

&c. alum-water, angelica-water, anniseed-water, apri-cot-water, aromatic-water, arthritic-water, bryony-water, carduus-water, water of separation, or depart, caustic-water, cephalic-water, chalybeat-water, cinnamon-water, clary-water, clove-water, cordial-water, cosmetic-water, gentian-water, gum-water, hepatic-water, honey-water, hungary-water, hysteric water, iced or frozen-water, imperial-water, lime-water, aqua mirabilis, or the wonderful-water, nephritic-water, ophthalmic-water, orange-water, peach-water, poppy-water, pyony-water, rose-water, scordium-water, specific-water, splenetic-water, stomachic-water, styptic-water, treacle-water, vulnerary-water, &c.

As these waters are exceeding numerous, and the manner of making them is not always the same, we must refer the chemical or medical reader to the dispensaries, wherein he will find, that every one gives his own method as the best one.

We have only three general remarks to add, with regard to those intended for drinking. 1. That such wherein any thing is infused, as bruised fruits, pounded herbs, &c. or ground spices, must be always passed through a filtre, to make them finer and purer. 2. That those made with brandy, or spirit of wine, are usually distilled after mixing their ingredients, which renders those liquors exceeding strong and dangerous. 3. That the waters which take their name from particular things, as cinnamon, &c. have often some other ingredients joined with them, according to the taste and smell required.

WATER ORDEAL, or TRIAL, among our ancestors, was of two kinds, by hot and by cold water. Trial or purgation by boiling or hot water, was a way of proving crimes, by immersing the body, or the arm, in hot water, with divers religious ceremonies. In the judgment by boiling water, the accused, or he who personated the accused, was obliged to put his naked arm into a caldron full of boiling water, and to draw out a stone thence placed at a greater or less depth, according to the quality of the crime. This done, the arm was wrapped up, and the judge set his seal on the cloth, and at the end of three days they returned to view it, when if it was found without any scald, the accused was declared innocent.

The nobles, or great personages, purged themselves thus, by hot-water, and the populace by cold water.

The trial, or purgation by cold water, was thus: after certain prayers and other ceremonies, the accused was swaddled, or tied up, all in a pelatoon or lump, and thus cast into a river, lake, or vessel of cold water, where if he sunk he was held criminal, if he floated innocent.

In the Levitical law, we find mention made of water which served to prove, whether or no a woman was an adulteress; the formula, as it was performed by the priest, may be seen in the fifth chapter of the book of Numbers.

WATER, among jewellers, is properly the colour or lustre of diamonds and pearls. The term, though less properly, is sometimes used for the hue or colour of other stones.

WATER-BAILIFF, is an officer in sea-port towns, appointed for the searching of ships; and in London, the water-bailiff hath the supervising and search of fish, brought thither; and the gathering of the toll arising from the Thames; his office is likewise to arrest men for debt, &c. or other personal or criminal matters upon the river Thames.

WATER-BORNE, in the sea-language. A ship is said to be water-borne, when she is, where there is no more water than will barely bear her from the ground; or when lying even with the ground, she first begins to float or swim.

WATER-COLOURS, in painting, are such colours as are only diluted and mixed up with gum-water, in contradistinction to oil-colours.

The use of water-colours makes what we call limning, as that of oil-colours does painting, properly so called.

WATER-FARCEY, a disease incident to horses, and is of two kinds; one the product of a feverish disposi-

tion terminating on the skin, as often happens in epidemical colds; the other is dropical, where the water is not confined to the belly and limbs, but shews itself in several parts of the body, by soft swellings yielding to the pressure of the finger. This last kind usually proceeds from foul feeding, or from the latter grass and fog, that often comes up in great plenty with continued cold rains, and breeds a sluggish viscid blood. In the former case, I have seen the limbs and whole body enormously swelled, and very hard, the belly and sheath greatly distended; which were as surprizingly reduced in four and twenty hours, by slight scarifications within side the leg and thigh, with a sharp penknife, and three or four strokes on the skin of the belly on each side the sheath; from these scarifications there was a constant and surprizing large dripping of water, which soon relieved the horse; when a few purges compleated his recovery.

In the other species of dropsy the curative intentions are to discharge the water, recover the crasis or strength of the blood, and brace up the relaxed fibres throughout the whole body. To this end, purge once a week or ten days; and give intermediately either of the following drinks, or balls.

Take black hellebore fresh gathered, two pounds; wash, bruise, and boil in six quarts of water, to four; then strain out the liquor, and put two quarts of white wine on the remaining hellebore, and let it infuse warm forty-eight hours; then strain off, mix both together, and give the horse a pint night and morning.

Take nitre two ounces, squills powdered, three drams, or half an ounce; camphor one dram, honey enough to form into a ball, to be given once a day alone, or washed down with a horn or two of the above drink.

Take of the leaves and bark of elder, of each a large handful; chamomile flowers half a handful, juniper berries bruised two ounces; boil in a quart of water to a pint and a half, to which add honey and nitre of each one ounce.

Give this drink every night, or night and morning; and to compleat the cure, and strengthen the whole body, give a pint of the subsequent infusion every night and morning, for a fortnight, fasting two hours after it.

Take gentian root and zedoary, of each four ounces; chamomile flowers and the tops of centaury, of each two handfuls; Jesuits bark powdered two ounces; juniper berries four ounces; filings of iron, half a pound: infuse in two gallons of ale for a week, shaking now and then the vessel.

Before we close this article, we think proper to lay down the symptoms of an incurable farcy, that the owners of such horses may save themselves unnecessary expence and trouble in their endeavours to obtain a cure.

When a farcy by improper applications, or by neglect has spread and increased; or after long continuance resisted the medicines above recommended; if fresh buds are continually sprouting forth, while the old ones remain foul and ill-conditioned; if they rise on the spines of the back and loins; if the horse grows hide-bound, and runs at the nose; if abscesses are formed in the fleshy parts between the interstices of the large muscles; if his eyes look dead and lifeless; if he forsakes his food and scours often, and his excrements appear thin, and of a blackish colour; if the plate, or thigh vein continue large after firing, and other proper applications: these symptoms denote the distemper to have penetrated internally, and that it will degenerate into an incurable consumption: it is also most probable, that the whole mass of fluids are tainted and become incurable by art. *Bartlett's Farriery.*

Dead WATER, in the sea-language, is the eddy-water that follows the stern of a ship, not passing away so fast as that which slides by her sides.

WATER GANG, a channel cut to drain a place by carrying off a stream of water.

WATER-LINE of a ship, a line which distinguishes that part of her under water from that above, when she is duly laden.

WATER-

WATER-MEASURE. Salt, sea-coal, &c. while aboard vessels in the pool or river, are measured with the corn-bushel heaped up; or else five stricked pecks are allowed to the bushel. This is called water-measure. See MEASURE.

WATER-MEN are such as row in boats, or ply on the river Thames, in the government of whom the lord-mayor of London, and court of aldermen there, had always great power. They still have the appointing of their fares, the taking more than which, makes them liable to a fine of forty shillings and half a year's imprisonment. The fares assessed are, from London-bridge to Limehouse, Ratcliff-cross, &c. oars, 1 s. scullers, 6 d. to Wapping-dock, Rotherhithe-church-stairs, &c. oars, 6 d. scullers, 3 d. from either side of the water above the Bridge to Lambeth and Vauxhall, oars, 1 s. scullers, 6 d. all the stairs between London-bridge and Westminster, oars, 6 d. scullers, 3 d.

Watermen's boats ought to be twelve feet and a half in length, and four and a half in breadth; and no apprentice to any waterman shall take upon him the care of a boat till he is sixteen years of age, if a waterman's son; and seventeen, if a landman's son, unless he has worked with some able waterman two years, &c.

No tilt-boat, or row-berge, &c. may take in above thirty-seven passengers, or three more by the way; nor any boat above eight passengers, and two by the way, else they forfeit 5 l. for the first offence, and 10 l. for the second, &c. and if any person be drowned when a greater number are taken in, the waterman is declared guilty of felony, and may be transported, &c.

WATER-MILL, a machine for grinding corn, &c. driven by the water.

In water-mills, the momentum of the falling water is the power; the force to be overcome is the great attrition of the two stones in grinding the corn, &c. which is effected wholly by a complication of wheels and axles. A query may here be put, Why, since the power constantly acts upon the wheel, the motion of the wheel should be equable, and not accelerated? The answer is, The increments of velocity keep rising, till their momentum is equalled by the resistance of the machine; after which æquilibrium, the wheel goes on with an uniform motion.

Dr. Barker has invented a mill of the most simple structure of any yet made, performing its effect without any wheel, trundle, cog, or round; the nature of the machine, and manner of its operation, will be easy to understand from the following account of its several parts:

A B C D (plate CXXXVIII. fig. 1.) is an upright frame standing on a proper base; E F is the wider part of G H an upright hollow pipe or tube, fixed at the bottom of an horizontal square trunk I K; which trunk, together with the tube, is fixed to an upright spindle or axis R S, by means of a nut and screw at S. The lower end of the axis on a fine point moves in the pivot-hole in the part of the frame at T; on the upper part of the frame is a hole through which the spindle passes, as also through the round circular piece P fixed on the said frame; on the upper part of the spindle is fixed another round circular piece O, which represents the upper moveable stone of the mill. Q is a spout of water filling the tube or trunk, and giving motion thereto, and, consequently, to the axis and upper stone, by the horizontal jets of water from each end of the trunk I K, through holes made at each end on contrary sides.

While the hole continue stopped, the trunk will be at rest, because then the pressure is equal over all the

While the holes continue stopped, the trunk will be at rest, because then the pressure is equal over all the parts; but when the holes are open, the pressure of the water (by its having liberty to issue out) will be less on that part where the hole is, than on the other part opposite to it; which stronger pressure will prevail, and carry round the trunk and tube with the axle and stone, in a contrary direction; and each hole contributes to produce this motion, which will be greater or lesser in proportion to the momenta of the jets of water, or greater or lesser aperture of the holes.

For it is easy to understand, that the power of this machine is derived from, or depends upon three things: 1. The velocity of the spouting-water; 2. The quantity thereof; and, 3. The distance at which the water spouts from the axis of motion. The two first make the momentum arising from the pressure of the fluid, which is proportional to the altitude, or height of the tube; the last is of a mechanical nature; for the trunk is in this respect exactly of the nature of the lever.

The ingenious Mr. Smeaton, in the Philosophical Transactions, Vol. LI. part I. has given us the following experimental observations concerning water-mills, which every mechanic will do well to observe, in constructing these useful machines.

Concerning UNDERSHOT WATER-WHEELS.

Plate CXXXVIII. fig. 2. is a perspective view of the machine for experiments on water-wheels; wherein

A B C D is the lower cistern, or magazine, for receiving the water, after it has quitted the wheel; and for supplying

D E the upper cistern, or head; wherein the water being raised to any height required, by a pump, that height is shewn by

F G, a small rod, divided into inches and parts; with a float at the bottom, to move the rod up and down, as the surface of the water rises and falls.

H I is a rod by which the sluice is drawn, and stopt at any height required, by means of

K a pin or peg, which fits several holes, placed in the manner of a diagonal scale, upon the face of the rod H I.

G L is the upper part of the rod of the pump, for drawing the water out of the lower cistern, in order to raise and keep up the surface thereof at its desired height, in the head D E; thereby to supply the water, expended by the aperture of the sluice.

M M is the arch and handle for working the pump, which is limited in its stroke by

N a piece for stopping the handle from raising the piston too high; that also being prevented from going too low, by meeting the bottom of the barrel.

O is the cylinder, upon which a cord winds, and which being conducted over the pulleys P and Q, raises

R, the scale, into which the weights are put, for trying the power of the water.

S T the two standards, which support the wheel, are made to slide up and down, in order to adjust the wheel, as near as possible, to the floor of the conduit.

W the beam which supports the scale and pulleys; this is represented as but little higher than the machine, for the sake of bringing the figure into a moderate compass, but in reality is placed 15 or 16 feet higher than the wheel.

Fig. 3. is a section of the same machine, wherein the same parts are marked with the same letters as in fig. 2. Besides which

X X is the pump barrel, being 5 inches diameter, and 11 inches long.

Y is the piston; and

Z the fixed valve.

G V is a cylinder of wood, fixed upon the pump-rod, and reaches above the surface of the water; this piece of wood being of such a thickness, that its section is half the area of that of the pump-barrel, will cause the surface of water to rise in the head, as much while the piston is descending, as while it is rising: and will thereby keep the gauge-rod F G more equally to its height. Note, the arch and handle M M is here represented on a different side to what it is shewn in the preceding figures, in order that its dimensions may the better appear.

aa shews one of the two wires which serve as directors to the float, in order that the gauge rod F G may be kept perpendicular; for the same purpose also serves w, a piece of wood with a hole to receive the gauge-rod, and keep it upright.

b is the aperture of the sluice.

c c a kant-board, for throwing the water more directly down the opening c d, into the lower cistern: and

cc is a sloping board, for bringing back the water that is thrown up by the floats of the wheel.

Fig. 4. represents one end of the main axis, with a section of the moveable cylinder, marked *O* in the preceding figures.

ABCD is the end of the axis; whereof the parts

B and *D* are covered with ferrules or hoops of brass.

E is a cylinder of metal; whereof the part marked

F is the pivot or gudgeon.

cc is the section of an hollow cylinder of wood, the diameter of the interior part being somewhat larger than the cylindrical ferrule *B*.

aa is the section of a ferrule of brass, driven into the end of the hollow cylinder, and which is adjusted to that marked *B*, so as to slide freely thereupon, but with as little shake as possible.

bb, dd, gg, represent the section of a brass ferrule, plate, and socket, fixed upon the other end of the hollow cylinder; the socket *dd* being adjusted to slide freely upon the cylinder *E*, in the same manner as the ferrule *aa* slides upon the cylinder *B*: the outer end of the socket at

gg is formed into a sort of button; by pushing whereof, the hollow cylinder will move backwards and forwards, or turn round at pleasure upon the cylindrical parts of the axis *B* and *E*.

ee, ii, oo, represent the section of a brass ferrule, also fixed upon the hollow cylinder: the edge of this ferrule

ee is cut into teeth, in the manner of a contrate wheel; and the edge thereof

oo is cut in the manner of a ratchet.

Of consequence, when the plate *bbdd* is pushed close to the ferrule *D*, the teeth of the ferrule *ee* will lay hold of

G, a pin fixed into the axis; by which means the hollow cylinder is made to turn along with the wheel and axis: but being drawn back by the button *gg*, the hollow cylinder is thereby disengaged from the pin *G*, and ceases turning.

Note. The weight in the scale is prevented from running back, by a catch that plays in and lays hold of the ratchet *oo*.

By this means the hollow cylinder upon which the cord winds, and raises the weight, is put in action and discharged therefrom instantaneously, while the wheel is in motion: for without some contrivance of this kind, it would not be easy to make this sort of experiments with any tolerable degree of exactness.

The use of the apparatus now described will be rendered more intelligible, by giving a general idea of what I had in view; but as I shall be obliged to make use of a term which has heretofore been the cause of dispute, I think it necessary to assign the sense in which I would be understood to use it; and in which I apprehend it is used by practical mechanicks.

The word power, as used in practical mechanicks, I apprehend to signify the exertion of strength, gravitation, impulse, or pressure, so as to produce motion: and by means of strength, gravitation, impulse, or pressure, compounded with motion, to be capable of producing an effect: and that no effect is properly mechanical, but what requires such a kind of power to produce it.

The raising of a weight, relative to the height to which it can be raised in a given time, is the most proper measure of power; or, in other words, if the weight raised is multiplied by the height to which it can be raised in a given time, the product is the measure of the power raising it; and consequently, all those powers are equal, whose products, made by such multiplication, are equal: for if a power can raise twice the weight to the same height; or the same weight to twice the height, in the same time that another power can, the first power is double the second: and if a power can raise half the weight to double the height; or double the weight to half the height, in the same time that another can, those two powers are equal. But note, all this is to be understood in case of flow or equable motion of the body raised; for in quick, accelerated, or retarded motions, the vis inertiae of the matter moved will make a variation.

In comparing the effects produced by water-wheels, with the powers producing them; or, in other words, to know what part of the original power is necessarily lost in the application, we must previously know how much of the power is spent in overcoming the friction of the machinery, and the resistance of the air; also what is the real velocity of the water at the instant that it strikes the wheel; and the real quantity of water expended in a given time.

From the velocity of the water, at the instant that it strikes the wheel, given; the height of head productive of such velocity can be deduced, from acknowledged and experimented principles of hydrostatics: so that by multiplying the quantity, or weight of water, really expended in a given time, by the height of head so obtained; which must be considered as the height from which that weight of water had descended in that given time; we shall have a product, equal to the original power of the water; and clear of all uncertainty, that would arise from the friction of the water, in passing small apertures; and from all doubts, arising from the different measure of spouting waters, assigned by different authors. On the other hand, the sum of the weights raised by the action of this water, and of the weight required to overcome the friction and resistance of the machine, multiplied by the height to which the weight can be raised in the time given, the product will be equal to the effect of that power; and the proportion of the two products will be the proportion of the power to the effect: so that by loading the wheel with different weights successively, we shall be able to determine at what particular load, and velocity of the wheel, the effect is a maximum.

The manner of finding the real velocity of the water, at the instant of its striking the wheel; the manner of finding the value of the friction, resistance, &c. in any given case; and the manner of finding the real expence of water, so far as concerns the following experiments, without having recourse to theory; being matters upon which the following determinations depend, it will be necessary to explain them.

To determine the Velocity of the Water Striking the Wheel.

It has already been mentioned, in the references to the figures, that weights are raised by a cord winding round a cylindrical part of the axis. First, then, let the wheel be put in motion by the water, but without any weights in the scale; and let the number of turns in a minute be 60: now it is evident, that was the wheel free from friction and resistance, that 60 times the circumference of the wheel would be the space through which the water would have moved in a minute; with that velocity wherewith it struck the wheel: but the wheel being incumbered by friction and resistance, and yet moving 60 turns in a minute, it is plain that the velocity of the water must have been greater than 60 circumferences before it met with the wheel. Let now the cord be wound round the cylinder, but contrary to the usual way, and put a weight in the scale; the weight so disposed (which may be called the counter-weight) will endeavour to assist the wheel in turning the same way, as it would have been turned by the water: put therefore as much weight into the scale as, without any water, will cause it to turn somewhat faster than at the rate of 60 turns in a minute; suppose 63: let it now be tried again by the water, assisted by the weight; the wheel therefore will now make more than 60 turns; suppose 64: hence we conclude the water still exerts some power in giving motion to the wheel. Let the weight be again increased, so as to make $64\frac{1}{2}$ turns in a minute without water: let it once more be tried with water as before; and suppose it now to make the same number of turns with water as without, viz. $64\frac{1}{2}$: hence it is evident, that in this case the wheel makes the same number of turns in a minute, as it would do if the wheel had no friction or resistance at all; because the weight is equivalent thereto; for was it too little, the water would accelerate the wheel beyond the weight; and if too great, retard it; so that the water now becomes a regulator of the wheel's motion; and the

the velocity of its circumference becomes a measure of the velocity of the water.

In like manner, in seeking the greatest product, or maximum of effect; having found by trials what weight gives the greatest product, by simply multiplying the weight in the scale by the number of turns of the wheel, find what weight in the scale, when the cord is on the contrary side of the cylinder, will cause the wheel to make the same number of turns the same way, without water; it is evident that this weight will be nearly equal to all friction and resistance taken together; and consequently, that the weight in the scale, with twice the weight of the scale, added to the back or counter-weight, will be equal to the weight that could have been raised, supposing the machine had been without friction or resistance; and which multiplied by the height to which it was raised, the product will be the greatest effect of that power.

The quantity of water expended is found thus:

The pump made use of for replenishing the head with water was so carefully made, that no water escaping back by the leathers, it delivered the same quantity of water at every stroke, whether worked quick or slow; and as the length of the stroke was limited, consequently the value of one stroke (or on account of more exactness 12 strokes) was known, by the height to which the water was thereby raised in the head; which being of a regular figure was easily measured. The sluice, by which the water was drawn upon the wheel, was made to stop at certain heights by a peg; so that when the peg was in the same hole, the aperture for the effluent water was the same. Hence the quantity of water expended by any given head, and opening of the sluice, may be obtained: for by observing how many strokes a minute was sufficient to keep up the surface of the water at the given height, and multiplying the number of strokes by the value of each, the water expended by any given aperture and head in a given time will be given.

These things will be further illustrated by going over the calculus of one sett of experiments.

Specimen of a Sett of Experiments.

The sluice drawn to the 1st hole.

The water above the floor of the sluice	—	30 inches.
Strokes of the pump in a minute	—	39½
The head raised by 12 strokes	—	21 inches.
The wheel raised the empty scale, and made turns in a minute	—	80
With a counter-weight of 1 lb. 8 oz. it made	—	85
Ditto tried with water	—	86

Nº.	Weight lb. oz.	Turns in a min.	Product.
1	4 0	45	180
2	5 0	42	210
3	6 0	36¼	217½
4	7 0	33¾	236¼
5	8 0	30	240 maximum.
6	9 0	26½	238½
7	10 0	22	220
8	11 0	16½	181½
9	12	ceased working.	

Counter weight, for 30 turns without water, 2 oz. in the scale.

N. B. The area of the head was 105,8 square inches.

Weight of the empty scale and pulley, 10 oz.

Circumference of the cylinder, 9 inches.

Circumference of the water wheel, 75 ditto.

Reduction of the above Sett of Experiments.

The circumference of the wheel, 75 inches, multiplied by 86 turns, gives 6450 inches for the velocity of the water in a minute; $\frac{1}{60}$ of which will be the velocity in a second, equal to 107,5 inches, or 8,96 feet, which is due to a head of 15 inches; and this we call the virtual or effective head.

The area of the head being 105,8 inches, this multiplied by the weight of water of the inch cubic, equal to the decimal, ,579 of the ounce averdupoise, gives 61,26

ounces for the weight of as much water, as is contained in the head, upon 1 inch in depth, $\frac{1}{60}$ of which is 3,83 pounds; this multiplied by the depth 21 inches, gives 80,43 lb. for the value of 12 strokes; and by proportion, 39½ (the number made in a minute) will give 264,7 lb. the weight of water expended in a minute.

Now as 264,7 lb. of water may be considered as having descended through a space of 15 inches in a minute, the product of these two numbers 3970 will express the power of the water to produce mechanical effects; which were as follows.

The velocity of the wheel at the maximum, as appears above, was 30 turns a minute; which multiplied by 9 inches, the circumference of the cylinder, makes 270 inches; but as the scale was hung by a pulley and double line, the weight was only raised half of this, viz. 135 inches.

The weight in the scale at the maximum 8 lb. 0 oz.

Weight of the scale and pulley — 0 10

Counterweight, scale, and pulley — 0 12

Sum of the resistance — 9 6

or lb. 9,375.

Now as 9,375 lb. is raised 135 inches, these two numbers being multiplied together, the product is 1266, which expresses the effect produced at a maximum: so that the proportion of the power to the effect is as 3970: 1266, or as 10: 3,18.

But though this is the greatest single effect producible from the power mentioned, by the impulse of the water upon an undershot wheel; yet, as the whole power of the water is not exhausted thereby, this will not be the true ratio between the power of the water, and the sum of all the effects producible therefrom: for as the water must necessarily leave the wheel with a velocity equal to the wheel's circumference, it is plain that some part of the power of the water must remain after quitting the wheel.

The velocity of the wheel at the maximum is 30 turns a minute; and consequently its circumference moves at the rate of 3,123 feet a second, which answers to a head, 1,82 inches; this being multiplied by the expence of water in a minute, viz. 264,7 lb. produces 481 for the power remaining in the water after it has passed the wheel: this being therefore deducted from the original power 3970, leaves 3489, which is that part of the power which is spent in producing the effect 1266; and consequently the part of the power spent in producing the effect, is to the greatest effect producible thereby as 3489: 1266 :: 10: 3,62, or as 11 to 4.

The velocity of the water striking the wheel has been determined to be equal to 86 circumferences of the wheel per minute, and the velocity of the wheel at the maximum to be 30; the velocity of the water will therefore be to that of the wheel as 86 to 30, or as 10 to 3,5, or as 20 to 7.

The load at the maximum has been shown to be equal to 9 lb. 6 oz. and that the wheel ceased moving with 12 lb. in the scale: to which if the weight of the scale is added, viz. 10 ounces, the proportion will be nearly as 3 to 4 between the load at the maximum and that by which the wheel is stopped.

It is somewhat remarkable, that though the velocity of the wheel in relation to the water turns out greater than $\frac{1}{3}$ of the velocity of the water, yet the impulse of the water in the case of a maximum is more than double of what is assigned by theory; that is, instead of $\frac{1}{3}$ of the column, it is nearly equal to the whole column.

It must be remembered, therefore, that, in the present case, the wheel was not placed in an open river, where the natural current, after it has communicated its impulse to the float, has room on all sides to escape, as the theory supposes; but in a conduit or race, to which the float being adapted, the water cannot otherwise escape than by moving along with the wheel. It is observable, that a wheel working in this manner, as soon as the water meets the float, receiving a sudden check, it rises up against the float, like a wave against a fixed object; in-fomuch that when the sheet of water is not a quarter of an inch thick before it meets the float, yet this sheet will

will

will act upon the whole surface of a float, whose height is 3 inches; and consequently was the float no higher than the thickness of the sheet of water, as the theory also supposes, a great part of the force would have been lost, by the water's dashing over the float.

In further confirmation of what is already delivered, I have adjoined the following table, containing the results of 27 sets of experiments, made and reduced in the manner above specified. What remains of the theory of undershot wheels, will naturally follow from a comparison of the different experiments together.

N ^o .	Height of the water in the cistern.	Turns of the wheel unloaded.	Virtual head deduced therefrom.	Turns at the maximum.	Load at the equilibrium.	Load at the maximum.	Water expended in a minute.	Power.	Effect.	Ratio of the power and effect.	Ratio of the velocity of the water and wheel.	Ratio of the load at the equilibrium, to the load at the maximum.	Experiments.

1.	2.	3.	4.	5.	6.	7.	8.	9.	10.	11.	12.	13.	

Maxims and Observations deduced from the foregoing Table of Experiments.

Maxim I. That the virtual or effective head being the same, the effect will be nearly as the quantity of water expended.

This will appear by comparing the contents of the columns 4, 8, and 10, in the foregoing sets of experiments; as for

Example 1st, taken from N^o. 8. and 25, viz.

N ^o .	Virtual Head.	Water expended.	Effect.
8	7,29	161	328
25	7,29	355	785

Now the heads being equal, if the effects are proportioned to the water expended, we shall have by maxim 1st, 161 : 355 :: 328 : 723; but 723 falls short of 785, as it turns out in experiment according to N^o. 25, by 62; the effect therefore of N^o. 25, compared with N^o. 8, is greater than according to the present maxim in the ratio of 14 to 13.

The foregoing example, with four similar ones, are seen at one view in the following table.

Examples	N ^o . Tab. I.	Virtual Head.	Expenditure of Water.	Effect.	Comparison.	Variation	Proportional Variation
1 st	8	7,29	161	328	161 : 355 :: 328 : 723	62 +	14 : 13
	25	7,29	355	785			
2 ^d	13	10,5	285	975	285 : 357 :: 975 : 1221	11 -	121 : 122
	18	10,5	357	1210			
3 ^d	22	6,8	255	541	255 : 332 :: 541 : 704	18 -	38 : 39
	23	6,8	332	686			
4 th	21	4,7	228	317	228 : 262 :: 317 : 364	21 +	18 : 17
	24	4,7	262	385			
5 th	26	5,03	307	450	307 : 360 :: 450 : 531	3 +	178 : 177
	27	5,03	360	534			

Hence

Hence therefore, in comparing different experiments, as some fall short, and others exceed the maximum, and all agree therewith, as near as can be expected, in an affair where so many different circumstances are concerned; we may, according to the laws of reasoning by induction, conclude the maxim true; viz. that the effects are nearly as the quantity of water expended.

Maxim II. That the expence of water being the same, the effect will be nearly as the height of the virtual or effective head.

This also will appear by comparing the contents of columns 4, 8, and 10, in an of the setts of experiments.

Example 1st, of N^o. 2. and N^o. 24. viz.

N ^o .	Virt. Head.	Expence.	Effect.
2	15	264,7	1266
24	4,7	262	385

Now as the expences are not quite equal, we must proportion one of the effects accordingly: thus

by maxim 1st, 262 : 264,7 :: 385 : 389
and by max. 2d, 15 : 4,7 :: 1266 : 397

Difference — 8

The effect therefore of N^o. 24. compared with N^o. 2. is less than according to the present maxim in the ratio of 49 : 50.

The foregoing, and two other similar examples, are comprised in the following table.

Examples.	N ^o . Tab. I.	Virtual Head.	Expence of Water.	Effect.	Comparison.	Variation.	Proportional Variation.
1st {	2	15	264,7	1266	Max. 1st, 262 : 264,7 :: 385 : 319	8 —	49 : 50
	24	4,7	262	385	Max. 2d, 15 : 4,7 :: 1266 : 397		
2d {	1	15,85	275	1411	Max. 1st, 114 : 275 :: 117 : 282	34 —	8 : 9
	10	3,55	114	117	Max. 2d, 15,85 : 3,55 :: 1411 : 316		
3d {	11	14,2	342	1505	Max. 1st, 167,5 : 342 :: 212 : 433	17 —	25 : 26
	17	4,25	167,5	212	Max. 2d, 14,2 : 4,25 :: 1505 : 450		

Maxim III. That the quantity of water expended being the same, the effect is nearly as the square of its velocity.

This will appear by comparing the contents of columns 3, 8, and 10, in any of the setts of experiments; as for

Example 1st of N^o. 2. with N^o. 24. viz.

N ^o .	Turns in a min.	Expence.	Effect.
2	86	264,7	1266
24	48	262	385

The velocity being as the number of turns, we shall have,

by max. 1st, 262 : 264,7 :: 385 : 389
and by max. 3d, $\left\{ \begin{matrix} 86^2 : 48^2 \\ 7396 : 2304 \end{matrix} \right\} :: 1266 : 394$
Difference - - - 5

The effect therefore of N^o. 24. compared with N^o. 2. is less than by the present maxim in the ratio of 78 : 79.

The foregoing, and three other similar examples, are comprised in the following table.

Examples.	N ^o . Tab. I.	Turns in a Minute.	Expence of Water.	Effect.	Comparison.	Variation.	Proportional Variation.
1st {	2	86	264,7	1266	Max. 1st, 262 : 264,7 :: 385 : 389	5 —	78 : 79
	24	48	262	385	Max. 3d, $\left\{ \begin{matrix} 86^2 : 48^2 \\ 7396 : 2304 \end{matrix} \right\} :: 1266 : 394$		
2d {	1	88	275	1411	Max. 1st, 114 : 275 :: 117 : 282	39 —	7 : 8
	10	42	114	117	Max. 3d, $\left\{ \begin{matrix} 88^2 : 42^2 \\ 7744 : 1764 \end{matrix} \right\} :: 1411 : 321$		
3d {	11	84	342	1505	Max. 1st, 167,5 : 342 :: 212 : 433	18 —	24 : 25
	17	46	167,5	212	Max. 3d, $\left\{ \begin{matrix} 84^2 : 46^2 \\ 7056 : 2116 \end{matrix} \right\} :: 1505 : 451$		
4 th {	18	72	357	1210	Max. 1st, 228 : 357 :: 317 : 496	42 —	12 : 13
	21	48	228	317	Max. 3d, $\left\{ \begin{matrix} 72^2 : 48^2 \\ 5184 : 2304 \end{matrix} \right\} :: 1210 : 538$		

Maxim 4th. The aperture being the same, the effect will be nearly as the cube of the velocity of the water.

This also will appear by comparing the contents of columns 3, 8, and 10; as for

Example 1st, of N^o. 1. and N^o. 10, viz.

N ^o .	Turns.	Expence.	Effect.
1	88	275	1411
10	42	114	117

Lemma. It must here be observed, that if water passes out of an aperture, in the same section, but with different velocities; the expence will be proportional to the velocity; and therefore conversely, if the expence is not proportional to the velocity, the section of the water is not the same.

Now comparing the water discharged with the turns of N^o. 1, and 10, we shall have 88 : 42 :: 275 : 131,2; but the water discharged by N^o. 10. is only 114 lb; there-

fore, though the sluice was drawn to the same height in N^o. 10. as in N^o. 1. yet the section of the water passing out, was less in N^o. 10. than N^o. 1. in the proportion of 114 to 131,2; consequently had the effective aperture or section of the water been the same in N^o. 10. as in N^o. 1. so that if 131,2 lb. of water had been discharged instead of 114, the effect would have been increased in the same proportion; that is,

by the lemma, 88 : 42 :: 275 : 131,2
by maxim 1st, 114 : 131,2 :: 117 : 134,5
and by max. 4th, $\left\{ \begin{matrix} 83^3 : 42^3 \\ 681472 : 74088 \end{matrix} \right\} :: 1411 : 153,5$
Difference — 19

The effect therefore of N^o. 10. compared with N^o. 1. is less than it ought to be by the present maxim in the ratio of 7 : 8.

The foregoing, and three other similar examples, are contained in the following table.

Examples.	No. Tab. I.	Turns in a minute.	Expende of Water.	Effect.	Comparison.	Variation.	Proportional Variation.
1st	{ 1 10	88 42	275 114	1411 117	{ Lemma. 88 : 42 :: 275 : 131,2 Max. 1. 114 : 131,2 :: 117 : 134,5 Max. 4. 88 ³ : 42 ³ :: 1411 : 153,5 }	19—	7 : 8
2d	{ 11 17	84 46	342 167,5	1505 212	{ Lemma. 84 : 46 :: 342 : 187,3 Max. 1. 167,5 : 187,3 :: 212 : 237 Max. 4. 84 ³ : 46 ³ :: 1505 : 247 }	10—	23 : 24
3d	{ 18 21	72 48	357 228	1210 317	{ Lemma. 72 : 48 :: 357 : 238 Max. 1. 228 : 238 :: 317 : 331,2 Max. 4. 72 ³ : 48 ³ :: 1210 : 355 }	24—	14 : 15
4th	{ 22 24	68 48	359 262	1006 385	{ Lemma. 68 : 48 :: 359 : 253,4 Max. 1. 262 : 253,4 :: 385 : 372 Max. 4. 68 ³ : 48 ³ :: 1006 : 354 }	18+	20 : 19

OBSERVATIONS.

Observ. 1st. On comparing column 2d and 4th, tab. I. it is evident, that the virtual head bears no certain proportion to the head of water; but that when the aperture is greater, or the velocity of the water issuing therefrom less, they approach nearer to a coincidence: and consequently in the large openings of mills and sluices, where great quantities of water are discharged from moderate heads, the head of water, and virtual head determined from the velocity, will nearly agree, as experience confirms.

Observ. 2d. Upon comparing the several proportions between the power and effect in column 11th, the most general is that of 10 to 3; the extremes 10 to 3,2 and 10 to 2,8; but as it is observable, that where the quantity of water, or the velocity thereof; that is, where the power is greatest, the 2d term of the ratio is greatest also: we may therefore well allow the proportion subsisting in large works, as 3 to 1.

Observ. 3d. The proportions of velocities between the water and wheel in column 12, are contained in the limits of 3 to 1 and 2 to 1; but as the greater velocities approach the limit of 3 to 1, and the greater quantity of water approach to that of 2 to 1, the best general proportion will be that of 5 to 2.

Observ. 4th. On comparing the numbers in column 13, it appears, that there is no certain ratio between the load that the wheel will carry at its maximum, and what will totally stop it; but that they are contained within the limits of 20 to 19, and of 20 to 15; but as the effect approaches nearest to the ratio of 20 to 15, or of 4 to 3, when the power is greatest, whether by increase of velocity, or quantity of water, this seems to be the most applicable to large works: but as the load that a wheel ought to have, in order to work to the best advantage, can be assigned, by knowing the effect it ought to produce, and the velocity it ought to have in producing it; the exact knowledge of the greatest load it will bear, is of the less consequence in practice.

It is to be noted, that in all the examples under the three last of the four preceding maxims, the effect of the lesser power falls short of its due proportion to the greater, when compared by its maxim; except the last example of maxim 4th: and hence, if the experiments are taken strictly, we must infer, that the effects increase and diminish in an higher ratio than those maxims suppose: but as the deviation is not very considerable, the greatest being about 1-8th of the quantity in question; and as it is not easy to make experiments of so compounded a nature with absolute precision; we may rather suppose, that the lesser power is attended with some friction, or works under some disadvantage, which has not been duly accounted for, and therefore we may conclude, that these maxims will hold very nearly, when applied to works in large.

After the experiments above mentioned were tried, the wheel, which had originally 24 floats, was reduced to twelve; which caused a diminution in the effect, on account of a greater quantity of water escaping between

the floats and the floor; but a circular sweep being adapted thereto, of such a length, that one float entered the curve before the preceding one quitted it, the effect came so near to the former, as not to give hopes of advancing it by increasing the number of floats beyond 24 in this particular wheel.

Concerning OVERSHOT WHEELS.

We now proceed to examine the power and application of water, when acting by its gravity on overshot wheels.

In reasoning without experiment, one might be led to imagine, that however different the mode of application is; yet that whenever the same quantity of water descends thro' the same perpendicular space, that the natural effective power would be equal; supposing the machinery free from friction, equally calculated to receive the full effect of the power, and to make the most of it: for if we suppose the height of a column of water to be 30 inches, and resting upon a base or aperture of one inch square; every cubic inch of water that departs therefrom will acquire the same velocity or momentum, from the uniform pressure of 20 cubic inches above it, that one cubic inch let fall from the top will acquire in falling down to the level of the aperture; viz. such a velocity as in a contrary direction would carry it to the level from whence it fell; one would therefore suppose, that a cubic inch of water, let fall thro' a space of 30 inches, and there impinging upon another body, would be capable of producing an equal effect by collision, as if the same cubic inch had descended thro' the same space with a slower motion, and produced its effects gradually: for in both cases gravity acts upon an equal quantity of matter, thro' an equal space; and consequently, that whatever was the ratio between the power and effect in undershot wheels, the same would obtain in overshot, and indeed in all others: yet, however conclusive this reasoning may seem, it will appear, in the course of the following deductions, that the effect of the gravity of descending bodies is very different from the effect of the stroke of such as are non-elastic, tho' generated by an equal mechanical power.

The alterations in the machinery already described, to accommodate the same for experiments on overshot wheels, were principally as follows.

Plate CXXXVIII. fig. 3. The sluice I b being shut down, the rod H I was unscrewed and taken off.

The undershot water-wheel was taken off the axis, and instead thereof an overshot wheel of the same diameter was put into its place. Note, This wheel was two inches in the shroud or depth of the bucket; the number of the buckets was 36.

The standards S and T, fig. 2, were raised half an inch, so that the bottom of the wheel might be clear of stagnant water.

A trunk, for bringing the water upon the wheel, was fixed according to the dotted lines f g, fig. 3. The aperture was adjusted by a shuttle h i, which also closed up the outer end of the trunk, when the water was to be stopped.

Fig.

Fig. 4. The ratchet *oo*, not being of one piece of metal with the ferrule *ee, ii* (tho' so described before, to prevent unnecessary distinctions), was with its catch turned the contrary side; consequently the moveable barrel would do its office equally, notwithstanding the water-wheel, when at work, moved the contrary way.

Specimen of a Sett of Experiments.

Head 6 inches.

14 $\frac{1}{2}$ strokes of the pump in a minute, 12 ditto = 80 lb.

Weight of the scale (being wet) 10 $\frac{1}{2}$ oz.

Counterweight for 20 turns, besides the scale, 3 oz.

Weight in

N ^o .	the scale.	Turns.	Product.	Observations.
1	0 lb.	60	—	Threw most part of the water out of the wheel.

Reduction of the preceding Specimen.

In these experiments the head being 6 inches, and the height of the wheel 24 inches, the whole descent will be 30 inches: the expence of water was 14 $\frac{1}{2}$ strokes of the pump in a minute, whereof 12 contained 80 lb.; therefore the water expended in a minute was 96 $\frac{2}{3}$ lb. which, multiplied by 30 inches, gives the power = 2900.

If we take the 20th experiment for the maximum, we shall have 20 $\frac{3}{4}$ turns in a minute, each of which raised the weight 4 $\frac{1}{2}$ inches, that is, 93,37 inches in a minute. The weight in the scale was 19 lb. the weight of the scale 10 $\frac{1}{2}$ oz.; the counter-weight 3 oz. in the scale, which, with the weight of the scale 10 $\frac{1}{2}$ oz. makes in the whole 20 $\frac{1}{2}$ lb. which is the whole resistance or load: this, multiplied by 93,37 inches, makes 1914 for the effect.

The ratio therefore of the power and effect will be as 2900:1914, or as 10:6,6, or as 3:2 nearly.

But if we compute the power from the height of the wheel only, we shall have 96 $\frac{2}{3}$ lb. multiplied by 24 inches = 2320 for the power, and this will be to the effect as 2320:1914, or as 10:82, or as 5:4 nearly.

The reduction of this specimen is set down in N^o. 9. of the following table; and the rest were deducted from a similar sett of experiments, reduced in the same manner.

Observations and Deductions from the foregoing Experiments.

I. Concerning the Ratio between the Power and Effect of Overshot Wheels.

The effective power of the water must be reckoned upon the whole descent; because it must be raised that height, in order to be in a condition of producing the same effect a second time.

The ratio's between the powers so estimated, and the effects at the maximum deduced from the several setts of

experiments, are exhibited at one view in column 9. of Table II. and from hence it appears, that those ratio's differ from that of 10 to 7,6 to that of 10:5,2, that is, nearly from 4:3 to 4:2. In those experiments where the heads of water and quantities expended are least, the proportion is nearly as 4:3; but where the heads and quantities are greatest, it approaches nearer to that of 4:2; and by a medium of the whole, the ratio is that of 3:2 nearly. We have seen before, in our observations upon the effects of undershot wheels, that the general ratio

ratio of the power to the effect, when greatest, was 3 : 1 ; the effect therefore of overshot wheels, under the same circumstances of quantity and fall, is at a medium double to that of the undershot : and, as a consequence thereof, that non-elastic bodies, when acting by their impulse or collision, communicate only a part of their original power ; the other part being spent in changing their figure in consequence of the stroke.

The powers of water computed from the height of the wheel only, compared with the effects, as in column 10. appear to observe a more constant ratio : for if we take the medium of each class, which is set down in column 11, we shall find the extremes to differ no more than from the ratio of 10 : 8,1 to that of 10 : 8,5 ; and as the second term of the ratio gradually increases from 8,1 to 8,5, by an increase of head from 3 inches to 11, the excess of 8,5 above 8,1 is to be imputed to the superior impulse of the water at the head of 11 inches above that of 3 inches : so that if we reduce 8,1 to 8, on account of the impulse of the 3 inch head, we shall have the ratio of the power, computed upon the height of the wheel only, to the effect at a maximum as 10 : 8, or as 5 : 4 nearly : and from the equality of the ratio between power and effect, subsisting where the constructions are similar, we must infer, that the effects, as well as the powers, are as the quantities of water and perpendicular heights multiplied together respectively.

II. Concerning the most proper Height of the Wheel in proportion to the whole Descent.

We have already seen, from the preceding observation, that the effect of the same quantity of water, descending thro' the same perpendicular space, is double, when acting by its gravity upon an over-shot wheel, to what the same produces when acting by its impulse upon an undershot. It also appears, that by increasing the head from 3 inches to 11, that is, the whole descent, from 27 inches to 35, or in the ratio of 7 to 9 nearly, the effect is advanced no more than in the ratio of 8,1 to 8,4, that is, as 7 : 7,26 ; and consequently the increase of effect as not 1-7th of the increase of perpendicular height. Hence it follows, that the higher the wheel is in proportion to the whole descent, the greater will be the effect ; because it depends less upon the impulse of the head, and more upon the gravity of the water in the buckets : and if we consider how obliquely the water issuing from the head must strike the buckets, we shall not be at a loss to account for the little advantage that arises from the impulse thereof ; and shall immediately see of how little consequence this impulse is to the effect of an overshot wheel. However, as every thing has its limits, so has this : for thus much is desirable, that the water should have somewhat greater velocity, than the circumference of the wheel, in coming thereon ; otherwise the wheel will not only be retarded, by the buckets striking the water, but thereby dashing a part of it over, so much of the power is lost.

The velocity that the circumference of the wheel ought to have, being known by the following deductions, the head requisite to give the water its proper velocity is easily computed from the common rules of hydrostatics ; and will be found much less than what is generally practised.

III. Concerning the Velocity of the Circumference of the Wheel, in order to produce the greatest Effect.

If a body is let fall freely from the surface of the head to the bottom of the descent, it will take a certain time in falling ; and in this case the whole action of gravity is spent in giving the body a certain velocity : but if this body in falling is made to act upon some other body, so as to produce a mechanical effect, the falling body will be retarded ; because a part of the action of gravity is then spent in producing the effect, and the remainder only giving motion to the falling body : and therefore the slower a body descends, the greater will be the portion of the action of gravity applicable to the producing a mechanical effect ; and in consequence the greater that effect may be.

If a stream of water falls into the bucket of an overshot wheel, it is there retained till the wheel by moving round discharges it : of consequence the slower the wheel moves, the more water each bucket will receive : so that what is lost in speed, is gained by the pressure of a greater quantity of water acting in the buckets at once : and, if considered only in this light, the mechanical power of an overshot wheel to produce effects will be equal, whether it moves quick or slow : but if we attend to what has been just now observed of the falling body, it will appear that so much of the action of gravity, as is employed in giving the wheel and water therein a greater velocity, must be subtracted from its pressure upon the buckets ; so that, though the product made by multiplying the number of cubic inches of water acting in the wheel at once by its velocity will be the same in all cases ; yet, as each cubic inch, when the velocity is greater does not press so much upon the bucket as when it is less, the power of the water to produce effects will be greater in the less velocity than in the greater : and hence we are led to this general rule, that, *cæteris paribus*, the less the velocity of the wheel, the greater will be the effect thereof. A confirmation of this doctrine, together with the limits it is subject to in practice, may be deduced from the foregoing specimen of a sett of experiments.

From these experiments it appears, that when the wheel made about 20 turns in a minute, the effect was, near upon, the greatest. When it made 30 turns, the effect was diminished about $\frac{1}{20}$ part ; but that when it made 40, it was diminished about $\frac{1}{4}$; when it made less than 18 $\frac{1}{4}$, its motion was irregular ; and when it was loaded so as not to admit its making 18 turns, the wheel was overpowered by its load.

It is an advantage in practice, that the velocity of the wheel should not be diminished further than what will procure some solid advantage in point of power ; because, *cæteris paribus*, as the motion is slower, the buckets must be made larger ; and the wheel being more loaded with water, the stress upon every part of the work will be increased in proportion : the best velocity for practice therefore will be such, as when the wheel here used made about 30 turns in a minute ; that is, when the velocity of the circumference is a little more than 3 feet in a second.

Experience confirms, that this velocity of 3 feet in a second is applicable to the highest overshot wheels, as well as the lowest ; and all other parts of the work being properly adapted thereto, will produce very nearly the greatest effect possible : however, this also is certain from experience, that high wheels may deviate further from this rule, before they will lose their power, by a given aliquot part of the whole, than low ones can be admitted to do ; for a wheel of 24 feet high may move at the rate of six feet per second without losing any considerable part of its power ; and, on the other hand, I have seen a wheel of 33 feet high, that has moved very steadily and well with a velocity but little exceeding 2 feet.

IV. Concerning the Load for an Overshot Wheel, in order that it may produce a Maximum.

The maximum load for an overshot wheel, is that which reduces the circumferences of the wheel to its proper velocity ; and this will be known, by dividing the effect it ought to produce in a given time by the space intended to be described by the circumference of the wheel in the same time : the quotient will be the resistance overcome at the circumference of the wheel ; and is equal to the load required, the friction and resistance of the machinery included.

V. Concerning the greatest possible Velocity of an Overshot Wheel.

The greatest velocity that the circumference of an overshot wheel is capable of, depends jointly upon the diameter or height of the wheel, and the velocity of falling bodies ; for it is plain that the velocity of the circumference can never be greater, than to describe a semi-circumference,

cumference, while a body let fall from the top of the wheel will descend thro' its diameter; nor indeed quite so great, as a body descending through the same perpendicular space cannot perform the same in so small a time when passing through a semi-circle, as would be done in a perpendicular line. Thus, if a wheel is 16 feet 1 inch high, a body will fall through the diameter in one second: this wheel therefore can never arrive at a velocity equal to the making one turn in two seconds; but in reality, an overshot wheel can never come near this velocity; for when it acquires a certain speed, the greatest part of the water is prevented from entering the buckets; and the rest, at a certain point of its descent, is thrown out again by the centrifugal force. This appears to have been the case in the three first experiments of the foregoing specimen; but as the velocity, when this begins to happen, depends upon the form of the buckets, as well as other circumstances, the utmost velocity of overshot wheels is not to be determined generally: and, indeed, it is the less necessary in practice, as it is in this circumstance incapable of producing any mechanical effect, for reasons already given.

VI. *Concerning the greatest Load that an overshot-wheel can overcome.*

The greatest load an overshot wheel will overcome, considered abstractedly, is unlimited or infinite: for as the buckets may be of any given capacity, the more the wheel is loaded, the slower it turns; but the slower it turns, the more will the buckets be filled with water; and consequently tho' the diameter of the wheel, and quantity of water expended, are both limited, yet no resistance can be assigned, which it is not able to overcome: but in practice we always meet with something that prevents our getting into infinitesimals; for when we really go to work to build a wheel, the buckets must necessarily be of some given capacity; and consequently such a resistance will stop the wheel, as is equal to the effort of all the buckets in one semi-circumference filled with water.

The structure of the buckets being given, the quantity of this effort may be assigned; but is not of much consequence to the practice, as in this case also the wheel loses its power; for though here is the exertion of gravity upon a given quantity of water, yet being prevented by a counterbalance from moving, is capable of producing no mechanical effect, according to our definition. But, in reality, an overshot wheel generally ceases to be useful before it is loaded to that pitch; for when it meets with such a resistance as to diminish its velocity to a certain degree, its motion becomes irregular; yet this never happens till the velocity of the circumference is less than two feet per second, where the resistance is equable, as appears not only from the preceding specimen, but from experiments on larger wheels.

Having now examined the different effects of the power of water, when acting by its impulse, and by its weight, under the titles of undershot and overshot wheels; we might naturally proceed to examine the effects when the impulse and weight are combined, as in the several kinds of breast-wheels, &c. but, what has been already delivered being carefully attended to, the application of the same principles in these mixt cases will be easy, and reduce what I have to say on this head into a narrow compass: for all kinds of wheels where the water cannot descend thro' a given space, unless the wheel moves therewith, are to be considered of the nature of an overshot wheel, according to the perpendicular height that the water descends from; and all those that receive the impulse or shock of the water, whether in an horizontal, perpendicular, or oblique direction, are to be considered as undershots. And therefore a wheel, which the water strikes at a certain point below the surface of the head, and after that descends in the arch of a circle, pressing by its gravity upon the wheel; the effect of such a wheel will be equal to the effect of an undershot, whose head is equal to the difference of level between the surface of the water in the reservoir and the point where it strikes the wheel, added to that of an overshot, whose height is equal to the dif-

ference of level, between the point where it strikes the wheel and the level of the tail-water. It is here supposed that the wheel receives the shock of the water at right angles to its radii; and that the velocity of its circumference is properly adapted to receive the utmost advantage of both these powers; otherwise a reduction must be made on that account.

Many obvious and considerable improvements upon the common practice naturally offer themselves, from a due consideration of the principles here established, as well as many popular errors shew themselves in view: but as my present purpose extends no farther than the laying down such general rules as will be found to answer in practice, I leave the particular application to the intelligent artist, and to the curious in these matters.

WATER-SHOOT, a young sprig which springs out of the root or stock of a tree.

WATER-TABLE, in architecture, a sort of ledge left in stone, or brick-walls, about eighteen or twenty inches from the ground, from which place the thickness of the wall begins to abate.

WATER-WAY, in a ship, is a small ledge of timber, lying fore and aft on the deck, close by her sides, to keep the water from running down there.

WATER-WHEEL, an engine for raising water in great quantity out of a deep well.

WATER-WORKS, in general, denote all manner of machines moved by, or employed in raising or sustaining water; in which sense, water-mills of all kinds, sluices, aqueducts, &c. may be called water-works.

The term water-works, however, is more particularly used for such machines as are employed only in raising water.

We shall begin with the description of that at London-bridge, which is moved by the common tide-water of the river Thames. *AB* (plate CXXXIX. *fig. 1.*) the axle-tree of the water-wheel, is nineteen feet long, three feet diameter, in which *C, D, E, F*, are four sets of arms, eight in each place, on which are fixed *G, G, G, G*, four rings, or sets of felloes, in diameter twenty feet; and the floats *H, H, H*, fourteen feet long, and eighteen inches deep, being about twenty-six in number.

The wheel lies with its two gudgeons, or center-pins *A B*, upon two brasses in the pieces *M N*, which are two great levers, whose fulcrum, or prop, is an arched piece of timber *L*: the levers being made circular on their lower sides to an arch of the radius *M O*, and kept in their places by two arching studs fixed in the stock *L*, through two mortises in the lever *M N*. The wheel is, by these levers, made to rise and fall with the tide, which is performed in this manner: the levers *M N* are sixteen feet long; from *M*, the fulcrum of the lever, to *O* the gudgeon of the water-wheel, six feet; and from *O* to the arch at *N*, ten feet. To the bottom of the arch *N* is fixed a strong triple chain *P*, made after the fashion of a watch-chain, but the links arched to a circle of one foot diameter, having notches, or teeth, to take hold of the leaves of a pinion of cast iron *Q*, ten inches diameter, with eight teeth in it moving on an axis. The other loose end of this chain has a large weight hanging at it, to help to counterpoise the wheel, and preserve the chain from sliding on the pinion. On the same axis is fixed a cog-wheel *R*, six feet diameter, with forty-eight cogs. To this is applied a trundle, or pinion *S*, of six rounds, or teeth; and upon the same axis is fixed *T*, a cog-wheel of fifty-one cogs, into which the trundle *V*, of six rounds, works; on whose axis is a winch or windlass *W*, by which one man, with the two windlasses, raises or lets down the wheel, as there is occasion. And because the fulcrums of these levers *M N* are in the axis of the trundle *K*, viz. at *M* or *X*, in what situation soever the wheel is raised or let down, the cog-wheel *I, I*, is always equidistant from *M*, and works or geers truly.

By means of this machine the strength of an ordinary man will raise about fifty ton weight.

I, I, is a cog-wheel fixed near the end of the great axis, eight feet diameter, and 44 cogs working into a

trundle K, of $4\frac{1}{2}$ feet diameter, and 20 rounds, whose axis or spindle is of cast iron 4 inches in diameter, lying in brasses at each end, as at X.

ZZ is a quadruple crank of cast iron, the metal being six inches square, each of the necks being turned one foot from the center, which is fixed in brasses at each end in two head-stocks fastened down by caps. One end of this crank at Y is placed close abutting to the end of the axle-tree X, where they are at those ends six inches diameter, each having a slit in the ends, where an iron wedge is put, one half into the end X, the other half into Y, by means of which the axis X turns about the crank ZZ.

The four necks of the crank have each an iron spear, or rod, fixed at their upper ends to the respective libra, or lever, *a* 1, 2, 3, 4, within three feet of the end. These levers are twenty-four feet long, moving on centers in the frame *bbbb*; at the end of which, at *c* 1, 2, 3, 4, are jointed four rods with their forcing plugs working into *d* 1, 2, 3, 4, four cast iron cylinders four feet three quarters long, seven inches bore above, and nine below where the valves lie, fastened by screwed flanches over the four holes of a hollow trunk of cast iron having four valves in it just over *eeee*, at the joining on at the bottom of the barrels, or cylinders, and at one end a sucking pipe or grate *f*, going into the water, which supplies all the four cylinders alternately.

From the lower part of the cylinders *d* 1, *d* 2, *d* 3, *d* 4, come out necks turning upward arch-wise, as *gggg*, whose upper parts are cast with flanches to screw up to the trunk *hhhh*; which necks have bores of seven inches

diameter, and holes in the trunk above communicating with them, at which joining are placed four valves. The trunk is cast with four bosses, or protuberances, standing out against the valves to give room for their opening and shutting; and on the upper side are four holes stopped with plugs, to take out on occasion, to cleanse the valves. One end of this trunk is stopped by a plug *i*. To the other iron pipes are joined, as *i* 2, by flanches, through which the water is forced up to any height or place required.

Besides these four forces, there are four more placed at the other ends of the libras, or levers (not shewn here to avoid confusion, but to be seen on the left hand) the rods being fixed at *a* 1, 2, 3, 4, working in four cylinders, with their parts *dd*, &c. *ee*, *f*, *gg* and *i*, as before described, standing near *kk*.

At the other end of the wheel (at B) is placed all the same sort of work as at the end A is described, viz.

The cog-wheel I.

The trundle K.

The spindle X.

The crank Y, Z.

The sucking pipes *f*.

The four levers *ac*, *ac*, &c.

Eight forcing rods, *ad*, *ad*, &c.

Eight cylinders, *de*, *de*, &c.

Four trunks, such as *ee*, *hh*.

Two forcing pipes, as *i*.

So that one single wheel works 16 pumps. All which work could not be drawn in one perspective view, without making it very much confused.

A Calculation of the Quantity of WATER raised by the Engines at London Bridge.

In the first arch next the city is one wheel with double work of ————— 16 forcers.

In the third arch { First wheel double work at one end, and single at the other ————— 12

{ Second wheel in the middle ————— 8

{ Third wheel ————— 16

In all 52 forcers.

One revolution of a wheel makes in every forcer ————— $2\frac{1}{2}$ strokes.

So that one turn of the four wheels makes ————— 114 strokes.

When the river is at best, the wheels go six times round in a minute, and but $4\frac{1}{2}$ at middle water 6

The number of strokes in a minute ————— 684

The stroke is $2\frac{1}{2}$ feet in a seven inch bore, raises ————— 3

They raise per minute ————— 2052 } ale gallons.

That is, 123120 gallons = 1954 hogsheds per hour, and at the rate of 46896 hogsheds in a day, to the height of 120 feet.

This is the utmost quantity they can raise, supposing there were no imperfections or loss at all.

But it is certain, from the considerations following, that no engine can raise so much as will answer the quantity of water the cylinder contains in the length of the forcers, or pistons motion. For,

First, opening and shutting of the valves lose nearly so much of that column, as the height they rise and fall.

Secondly, no leather is strong enough for the piston, but there must continually slip, or squeeze by, some water, when it is raised to a great height; and, when the column is short, it will not press the leather enough to the cylinder, or barrel: but, especially at the beginning or first moving of the piston, there is so little weight

on it, that, before the leather can expand, there is some loss.

Thirdly, and this loss is more or less, as the pistons are looser or straiter leathered.

Fourthly, when the leathers grow too soft, they are not capable of sustaining the pillar to be raised.

Fifthly, if they are leathered very tight, so as to lose no water, then a great part of the engine's force is destroyed by friction.

By some experiments accurately made on engines, whose parts are large and excellently performed, they will lose one fifth, and sometimes one fourth of the calculated quantity.

However, the perfections or errors of engines are to be compared together, by the calculated quantities of forcers; for as they differ in those, they will proportionably differ in their actual performances.

The Power by which the Wheels are moved.

The weight of the pillar of water on a forcer seven inches diameter and 120 feet high.

$7 \times 7 = 49$ f. The pounds avoirdupoise in a yard, nearly.

40 yards high.

1960 f. on one forcer.

8 forcers always lifting.

The whole weight 15680 f. = 140 Cwt. = 7 ton weight on the engine at once,

Then

Then the crank pulls the libra 3 feet from the forcer, and 8,3 feet from the center,

$$\begin{array}{rcl}
 & 7 \text{ ton} & \\
 & \times 11.3 & \\
 \hline
 & 8,379.1(9,5 \text{ ton on the crank} & \\

 & & 20
 \end{array}$$

The force on the floats 18 Cwt. 40 lb. 34,40 Cwt.

But to allow for friction and velocity, may be reckoned 1 ton $\frac{1}{2}$.

The ladles, or paddles, 14 feet long, 18 inches deep, = 22,4 square feet.

The fall of water is at a mean --- 2 feet

44,8

6 gallons in a cubic foot:

268,8

10, lb. in a gallon.

112)2688(24 hundred.

The velocity of the water, 4 feet in 21''' of time.

21''' - 4 feet :: - 60'' : = 685 feet per minute.

The velocity of the wheel = 310 feet per minute.

Quantity expended on the wheel, according to the velocity of the stream, 1433 hogheads per second.

But at the velocity of the wheel 645 hogheads per second.

The velocity of the wheel to the velocity of the water, as 1 to 2,2:

Fig. 2. plate CXXXIX. represents a curious machine for raising water, executed at Nynphenbourg, by the count de Whal, master of the works to the elector of Bavaria. It raises water sixty feet high into a reservoir, for the use of the elector's gardens.

The water of the canal, falling down the inclined plane at Q, turns the large wheel represented in the figure, the circumference of which, by cogs, moves the arbor D, and the same on the other side; to those are fastened the pistons of sixteen forcing pumps G, four on each side the arbor, as represented in the figure.

From each of these pumps is a tube, through which the water is forced into the pipe O, and from thence through the pipe P, which conveys it into the reservoir. These pumps are fastened together by pieces of timber, with iron clamps, to make them firm, as may be seen in the figure.

This is a very good machine, and deserves to be imitated, either in whole or in part, when water is to be raised.

We shall conclude this account of water-works with a description of two machines much used in Holland.

Fig. 3. represents another machine for raising water: it is moved by the man C, walking in the wheel C, as is plain from the figure. The large wheel A, A, G, has seven square holes in its circumference, as A, A, A, which run in a spiral form to the axis B. The water, by the motion of the wheel whose circumference is constantly immersed in it, runs along these spiral tubes to the axis; from whence it is conveyed to D, where it is discharged, and by means of the trough and spout F, F, conveyed to the reservoir destined to receive it.

Fig. 4. represents a machine used by the Dutch for freeing their dykes of water. It consists of five pieces of board, forming a kind of scoop, as B; the handle C is suspended by a rope fastened to three poles placed triangularly, and fastened together at A, as is plain from the figure. As the working of this machine consists in balancing it, and directing it so that, after having filled it with water, it may throw it on the other side of the dam, we shall only observe that the labourer at two strokes can draw only half a cubic foot of water in four seconds, which amounts to four hundred cubic feet in an hour.

Fig. 5. is another machine of the same kind with that above described. The figure sufficiently explains its use. It is worked by two men, one at A, and another at D. The machine moves on the center B, and each end is immersed alternately in the water; by which means it flows into each end of the machine where there is a valve, to prevent its returning; and, by the alter-

nate motion of the machine, the water so taken up is conveyed to B, and from thence, by the spout C, over the dam.

WATERING, in the manufactures, is to give a lustre to stuffs, &c. by wetting them lightly with gum-water, and then passing them through the press, or calendar, whether hot or cold.

The gum-water ought to be pure, thin, and clear, otherwise the folds of the stuff will stick together: the operation must also be performed when the water is very hot, that it may penetrate.

WAVE, *Unda*, in philosophy, a cavity in the surface of water, or other fluid, with an elevation aside thereof.

Sir Isaac Newton explains the nature of waves in water after the following manner: Let AB and CD (plate CXXXIX. fig. 6.) be the surface of water quiescent in the upright legs KL, MN, of a received tube. And if the water be put into motion, and ascends in the leg KL to EF, it will descend in the leg MN to GH; so that EA = DH. Again, let PV be a pendulum vibrating in the cycloid RPS, its length VP, from the point of suspension to the center of oscillation, is equal to half the length of the water in the tube; let P be the lowest point, and PQ an arch of the cycloid, equal to the altitude AE.

The force by which the water is alternately accelerated and retarded in its motion in the tube, is the excess of the weight of water in either leg above the weight in the other; and, therefore, when the water in the leg KL ascends to EF, and in the other leg descends to GH, that force is equal to the weight of the two equal quantities of water AEFB + CGHD = 2AEFB; and, therefore, is to the weight of the whole water, as EA to VP, or as PQ to PR, because the semi-cycloid PR is equal to the length of the pendulum, which describes it from the nature of the curve.

All the power by which the weight P is in any point Q accelerated or retarded in the cycloid, is, to its whole weight, as the distance PQ from the lowest point P to the length of the semi-cycloid PR. Wherefore, as the moving forces of the water and pendulum are at first quiescent, those powers will move them equally in equal times, and cause that they go forwards and backwards together, with a reciprocal motion. All which is easily deduced, from what has been said of the nature of the cycloid, the motion of heavy bodies, and the forces of bodies in motion.

Hence it follows, that, whether the distance AE be great or small, the reciprocations of the water will all be performed

performed in equal times. Also, it follows, that if the whole length of the water be 78,4 inches, each reciprocation, or ascent and descent of the water, will be performed in one second of time; because a pendulum of half that length vibrates in that time. Lastly, if the length of the aqueous canal be increased or diminished, the time of each reciprocation will be increased or diminished in the subduplicate ratio of the length.

When the nature of waves in water is considered, it will be found to agree very nearly with the motion of the water in the tube abovementioned; and, consequently, their motion will be similar to that of a pendulum. For let EFG (fig. 7.) represent the level surface of water when it is not agitated, so as to produce waves; when it is thus agitated, let ABCD represent the wavy surface, AC the highest parts of the waves, and BD the lowest or concave part. Then it is evident, the weight of the water at A above EG will cause it to descend as far below the level to B; and with the motion acquired by that descent, it will again ascend to the same height C, and so produce a constant succession of waves in the watery surface, after the same manner as was shewn in the tube.

Hence it follows, that because the length of the whole water to be moved is from the highest point A to the lowest point B, if the length of a pendulum be half AB, it will oscillate once while the water descends from A to B, and in another oscillation, it will ascend from B to C, and so on. So that a wave will pass through its whole length in the time of two oscillations; and, therefore, in the time of one oscillation of a pendulum four times as long, or equal to ABC.

Whence, because ABC, in very large and wide waves, is nearly equal to the breadth AC; therefore, when the waves are 39,2 inches broad, they will undulate in one second of time; and, consequently, since the times of all the undulations are equal, there will be $39,2 \times 60 = 2352$ inches or 196 feet, run through by a wave in one minute, which is 11760 feet per hour. Hence, also the velocity of greater or lesser waves will be increased or diminished in the subduplicate proportion of their breadth; that is, if $V =$ velocity of the greater waves ABCD, and $v =$ velocity of the lesser waves a, b, c, d, e, f , &c. then it will be $V : v :: \sqrt{AC} : \sqrt{ac}$. Because the velocities and times of bodies, moved in any manner by gravity, are proportional to the square roots of the perpendicular altitudes, and those altitudes are as the lengths of pendulums, and, therefore, as the breadth of waves.

WAVE-OFFERING, in Jewish antiquity, a sacrifice offered by agitation, or waving, towards the four cardinal points of the compass.

WAVED, WAVY, or WAVEY, in heraldry, is said of a bordure, or any ordinary, or charge, in a coat of arms, having its out-lines indented in manner of the rising and falling of waves; it is used to denote, that the first of the family in whose arms it stands, acquired its honours for sea-service.

WAVING, in the sea-language, is the making signs to a vessel to come near or keep off.

WAX, or Bees-WAX, is one of the products of the bee-hive, which, though it is, as well as the honey, of a vegetable origin, yet, as we have no way of procuring it but by means of the bees that have stored it up for us, is to be reckoned in the same manner as the honey among the number of drugs which we receive from the animal kingdom.

Wax is a firm and solid substance, moderately hard, and of a fine yellow colour; it melts with a gentle heat, and is inflammable; it is soluble in oil, but not in aqueous or spirituous menstruums; it is almost insipid to the taste, but of a fragrant and agreeable smell; and, in its original state, is the matter which composes the honey-comb; it is prepared in the cakes we see it in, merely by melting, and straining through a cloth, which separates the dross and foulness, and lets the clear wax through. It may be further purified by melting again, and scumming it, while in fusion, and repeating the straining; by this means it will become of a good consistence, and high colour; it is to be chosen of a strong yellow colour,

and fragrant smell; and such as breaks tolerably easy, and on chewing in the mouth, does not stick to the teeth.

The true origin of wax is this: the flowers of plants have, for one of their principal and essential parts, certain filaments, or threads, called by the botanical writers, stamina, rising usually from the base or center; these are different in number, from one to a vast abundance in each flower: these sustain at their tops certain little bodies, usually of a round, but sometimes of other figures, called by the same authors apices, or antheræ, and containing a fine dusty matter, or variously coloured powder. These stamina and apices were long esteemed of very little use to the plant, mere ornaments, or the receptacles of an abundant juice sent up the flower; but of late, botany has received too many improvements to be left chargeable with so gross an error: these are discovered to be essential to the great end, the propagating the species of the plant; they are, indeed, the male plants, serving to impregnate the young seeds in the pistil, and the impregnating matter is found to be dust or powder in these apices; this is called, therefore, the farina fecundans of plants; and however little this may have been suspected to have to do with our subject, it is, indeed, the very thing of which the bees form their combs, or, in other words, the farina of plants is wax not yet reduced to form by the bees. These little creatures seek no farther for the materials of their combs than to the apices of flowers; these, if of a more solid and firm texture, they are at the pains of opening with their teeth; or, if less tough or already opening, they rob of their farina, by rubbing their bodies among them, and so dislodging the dust which adheres to their bodies by means of the hairs they are covered with, and is thence collected into a mass.

Wax is, indeed, excellently fitted for these purposes, being a kind of fatty resin and turpentine, and qualified to answer all the uses of a mixed body of that nature. It is, indeed, so evidently a vegetable production in its original, that it has not only been found almost pure in the farina of plants, but it is, sometimes, exsulated from their very leaves. There is scarce any known plant, the stamina of which seem so much to abound with wax, as those of rosemary; and these are not the only part that contains it. Whosoever will handle the leaves of rosemary, will find a viscid matter in considerable quantity; and this will, on continuing to handle them, be collected on the fingers in such quantity, as to be rolled off in little lumps, which, when examined, are real wax, at least, as pure as that in the farina of any plant in the world.

Spirit of wine, digested on fresh rosemary leaves, will also draw a sort of tincture from this waxy matter on their surface, and this, when evaporated, will yield the same smell of wax as the tincture of the farina does, and will leave the same kind of soluble wax in the cake at least.

However singular the total volatility of wax may appear to those not used to chymical experiments, there is this to be observed in regard to it, that it shews the truth of the assertion, that it approaches the nature of turpentine; for turpentine, with a fire properly managed, will in the same manner all rise over into the receiver: both these substances agree, also, with camphire, in this respect; though the disparity between camphire and them, in regard to the degree of volatility, or the degree of fire necessary to raise them, is immense. They all have their separate qualities also; after having been thus raised by fire, camphire becomes camphire again, and not a liquid oil; the very liquid oil of turpentine kept a considerable time loses its fluidity, and becomes as thick as the turpentine it was made from; whereas, the butter of wax remains unaltered for ever so great a number of years, never becoming thicker than at first. It is also singular, that the repeated distillations of it, though they render it more thin and fluid, and greatly more penetrating, yet it becomes all the time more mild and gentle, less, not more, acrimonious, as might be expected.

From the common yellow wax, by the mere effect of sun and air, or by what is called bleaching, is formed what we term white-wax; and some, very improperly, virgin-wax. As the greater the surface is in proportion

to the quantity, the sooner and more perfectly this operation is performed. The usual way is to melt the wax in hot water; when melted, they press it through a strainer of tolerable fine linen, and pour it into round and very shallow moulds. When hardened by cooling, it is taken out and exposed to the sun and air, sprinkling it now and then with water, and often turning it: by this means it soon becomes white. The best sort is of a clear and almost transparent whiteness, dry, hard, brittle, and of an agreeable smell, like that of the yellow wax, but much weaker.

The common yellow wax is of very great use both in medicine and in many of the arts and manufactures. It is sometimes given internally, as in dysenteries, and other erosions of the intestines; but its great use is in the making ointments and plasters for external use, and the greater part of those of the shops owe their consistence to it. The white-wax is also an ingredient in some of the cerates and ointments of the shops; and is used in making candles, and in many of the nicer arts and manufactures, where wax is required.

Preparations of WAX. The butter and oil of wax are thus prepared: cut the wax in pieces and put them into a retort, which must be half filled with these pieces; and the rest of the retort being filled with sand, it must be placed in a sand furnace. At first an acid spirit arises, and afterwards a thick oil, called the butter of wax, sticks in the neck of the retort, unless it be heated by applying a live coal. This may be rectified into a thin oil, by distilling it several times, without addition, in a sand-heat. The butter is an extremely soft and anodyne unguent; highly emollient and relaxing; agreeable to the nerves; and when rubbed on contracted limbs, proves of great benefit to them. It is an excellent liniment for the piles, and takes off the pain attending them in a very sudden and surprising manner. It also keeps the skin soft, and is one of the best things known to keep it from cracking or chopping in the winter.

The oil of wax has also a very singular virtue in curing contracted tendons and restoring flexibility to the parts. It cures chapped nipples in women who give suck beyond any other application, and is as successful against chapped lips, and the cracking of the skin of the hands, only rubbing them once in three or four days with it. It is also of great use in discussing cold tumours arising on the face, and those on the fingers in winter.

Sealing-WAX is made in the following manner: take one pound of bees-wax; three ounces of fine turpentine; olive-oil, and rosin, finely powdered, of each one ounce: when they are well melted, and the dross taken off, put in an ounce and a half of vermillion, or red-lead, finely ground, and stir them together till they are well incorporated: and when this mixture grows a little cool roll it into sticks, or in any other form. If you would have it black, instead of vermillion, or red-lead, put in lamp-black. The soft, red, and green wax, used in large seals to some of our law-writings, are thus made: melt bees-wax over a gentle heat, with such a proportion of Venice turpentine as, when cold, will give it the due consistence: this is determined by repeated trials, first putting in but little turpentine, and afterwards more and more, till by dropping a piece upon a marble to cool, it is found of the true consistence. They then colour it with red-lead, or vermillion, or with verditer, or whatever colours they please; the mixture in this state receiving any.

Grafting-WAX, a composition serving to bind the graft to the cleft of the stock. For the manner of making which, see *Methods of GRAFTING*.

To imitate fruit in WAX. Take the fruit and bury it half way in clay; oil its edges, and that part of the fruit which is uncovered; then nimbly throw on it tempered alabaster or plaster of Paris, to a considerable thickness. When this is grown dry and hard, it makes the half mould; the second half of which may be obtained in the same manner. The two parts of the mould being joined together, a little bees-wax melted and brought to a due heat, being poured through a hole made in a convenient

part of the mould, and presently shook therein, will represent the original fruit.

WAX-WORK, the representation of the faces, &c. of persons living or dead; made by applying plaster of Paris in a kind of paste, and thus forming a mould containing the exact representation of the features. Into this mould melted wax is poured, and thus a kind of masks are formed; which being painted and set with glass eyes, and the figures dressed in their proper habits, they bear such a resemblance that it is difficult to distinguish between the copy and the original.

WAXING, in chemistry, the preparation of any matter to render it fit and disposed to liquify, or melt, which of itself it was not.

This is frequently done to enable things to penetrate into metals and other solid bodies.

WAY, a passage or road. See *ROAD*.

The Roman ways are divided into consular, prætorian, military, and public; and of these we have four remarkable ones in England: the first, Watling-street, or Watheling-street, leading from Dover to London, Dunstable, Towcester, Atterston, and the Severn, extending as far as Anglesea in Wales. The second, called Hikenild, or Ikenild-street, stretches from Southampton over the river Isis at Newbridge; thence by Camden and Lichfield; then passes the Derwent, near Derby, and ends at Tintmouth. The third, called Fosse-way, because in some places it was never perfected, but lies as a large ditch, leads from Cornwall through Devonshire, by Tethbury, near Stow in the Wolds; and beside Coventry to Leicester, Newark, and so to Lincoln. The fourth, called Erming, or Erminage-street, extends from St. David's, in Wales, to Southampton.

WAY of a Ship, is sometimes the same as her rake, or run forward or backward: but this term is most commonly understood of her sailing. Thus when she goes apace, it is said that she hath a good way, or makes a fresh way. So when an account is kept how fast she sails by the log, it is called keeping an account of her way; and because most ships are apt to fall a little to leeward of their true course, they always in casting up the log-board, allow something for her leeward way.

WAY of the Rounds, in fortification, is a space left for the passage of the rounds between the rampart and the wall of a fortified town. This is not now much in use; because the parapet, not being above a foot thick, is soon overthrown by the enemy's cannon.

WAY-WISER, an instrument otherwise called perambulator. See *PERAMBULATOR*.

WAY-WODE, a title given to the governors of the chief places in the empire of Muscovy, as also in Poland.

WEAR, or *WEER*, a great flank or dam in a river, fitted for the taking of fish, or for conveying the stream to a mill.

New wears are not to be made, or others altered, to the nuisance of the public, under a certain penalty.

WEASEL, in zoology, a species of mustela, with the tip of the tail black.

This is a smaller animal than the pole-cat: the head is small, of an ovated form, and sharp at the snout: the ears are small, short, and patulous; the eyes of a fierce aspect; the mouth well furnished with teeth; the upper jaw longer than the under: the body is about eight inches long, and slender: the tail is a third part the length of the body; the legs are short and slender; the feet have five toes armed with sharp claws; the whole body is covered with a fine and tolerably long fur: the back is of a darkish colour, and the belly is white.

WEATHER, the state or disposition of the atmosphere, with regard to heat, cold, wind, rain, frost, &c.

As it is in the atmosphere that all plants and animals live and breathe, and as that appears to be the great principle of most animal and vegetable productions, alterations, &c. there does not seem any thing, in all philosophy, of more immediate concernment to us, than the state of the weather, and a knowledge of the great influ-

influence it has on our bodies, and the sensible alterations we undergo thereby. In effect, all living things are only assemblages or bundles of vessels, whose juices are kept moving by the pressure of the atmosphere; and which, by that motion, maintain life: so that any alteration in the rarity or density, the heat, purity, &c. of that, must necessarily be attended with proportionable ones in these.

What vast, yet regular alterations, a little turn of weather makes in a tube filled with mercury, or spirit of wine, or in a piece of string, &c. every body knows, in the common instance of barometers, thermometers, &c. and it is owing partly to our inattentions, and partly to our unequal, intemperate, course of living, that we do not feel as great and regular ones in the tubes, chords, and fibres of our own bodies. It is certain, a great part of the brute creation have a sensibility and sagacity, this way, beyond mankind; and yet, without natural means or disposition thereto, more than we; except that their vessels, fibres, &c. being in other respects in one equal habitude, the same cause from without has always a like effect on them; that is, their vessels are regular barometers, &c. affected only from one external principle, the disposition of the atmosphere; whereas ours are acted on by divers from within, as well as without; some of which check, impede, and prevent the action of others.

There is nothing more wanting than a just theory of the weather on mechanical principles. But in order to that, a complete history of the weather would be required. Were registers carefully kept in divers places of the earth, for a good series of years, we should be able to determine the directions, breadth, and bounds of the winds, and of the weather they bring with them; the correspondence between the weather of divers places, and the dependence between one sort and another of the same place. In time, we might learn to foretel heats, rains, frosts, dearths, plagues, and other epidemical diseases, &c.

WEATHER-COCK, or **WEATHER-VANE**, a moveable vane in form of a cock, or other shape, placed on high, to be turned round according to the direction of the wind, and point out what quarter the wind blows from. See **WIND**.

WEATHER-GLASSES, are instruments contrived to indicate the state or disposition of the atmosphere, and the various alterations in the weather; such are barometers, thermometers, hygrometers, &c.

WEATHER-GAGE, in the sea-language. See the article **GAGE**.

WEATHERING, among sailors, signifies the doubling, or sailing by a head-land, or other place.

WEAVING, the art of working a web of cloth, silk, or other stuff, in a loom with a shuttle.

WEAVING-LOOM, a machine for weaving cloth, silk, &c. by raising the threads of the warp in order to throw in the shoot, and strike it close. Of these there are various kinds, distinguished by the different sorts of cloths, stuffs, silks, &c. in which they are employed, and which are chiefly distinguished by the number and variety of the threads they raise in order to work the warp, either plain or in figures, by making more or less of the woof or shoot appear through the warp.

In order to give a general idea of weaving, we shall here describe the parts of the common weaver's loom. See plate CXL. fig. 1. in which 9, 9, are the loom-posts; 10, the cross-bars; 11, the batten, which serves to strike in, and close more or less the threads of the woof; 12, the cap of the batten, or a long bar, which the weaver takes hold of in one hand and then in the other; 13, the block, or under part of the same, containing the reed within the lower bar; 14, the cross-piece, or burdon and pin, which helps to make the batten moveable; 15, the gallows, a piece of wood suspending the pulley, on which the cord moves that is tied to the two lams; 16, the breast-bar, a flat square piece of wood, with an opening in it to let the stuff through, which is rolled on the knee-roll; 17, the cane-roll,

which the warp is turned on at the other end of the loom; 18, the reed; 19, pulleys upon which the cords roll that are fastened to the lams; 20, the tumbler, which is a cord that passes from one lam to the other over the pulley 21, and causes the working of the lams by its ascending and descending; 22, the muffle, in which the pulley acts; 23, a skain, or leish, cut into proper lengths, to mend the leishes of the harness that happen to break; 24, a bobbin of the warp, to mend the threads of the warp that occasionally break; 25, lizard thread to mend those of the lizier that happen to break; and which, especially in cloth, are very different from the warp; 26, the box to hold the quills; 28, the foot-bar; 29, the trundles, or moveable bars, tied with two cords to the lower virgee of each lam. When the foot presses a treddle, the lam that is fastened to it sinks, and the other rises by the help of the tumbler; 30, the foot-step; 31, the temple; a double flat ruler, having small teeth at the extremities; it may be lengthened or shortened by the help of a catch that is in one of the rulers, and introduced in a groove in the other ruler. The teeth in the extremities are fastened in the lizier of the work, by which means it is kept of an equal breadth; and as the work advances the temple is moved forwards; 32, the shuttle seen in front and profile; 33, the knee roll, on which the work is rolled as it is wove; 34, the tantow; an iron leaver to turn the knee-roll; 35, the reed seen separate.

WEB, a sort of tissue, or texture formed of threads interwoven with each other; some whereof are extended in length, and called the warp; and others drawn across, and called the woof. See the articles **CLOTH**, **WARP**, &c.

Spider's WEB, or **Cob-WEB**, is a very delicate and wonderful plexus, which that insect spins out of its own bowels, serving it as a sort of toil, or net to catch flies, &c. withal. For the manner wherein the spider spins his web, the admirable mechanism of the parts subservient thereto, and the uses thereof, see the articles **SPIDER**, and **Spider's SILK**.

WEDGE, *Cuneus*, the last of the five mechanical powers. It is a triangular prism, whose bases are equilateral acute-angled prisms.

The power of the wedge ACBH (plate CXL. fig. 2.) is evident from its consisting of two equal inclined planes AHC and BHC; as it is chiefly of use to separate the adhering parts of wood, and since the power of cohesion in wood is every where variable and uncertain, it is evident there can be no regular calculation of the actual effect of the wedge; but if we suppose the power of cohesion in the wood ADEB to be uniform, or to make every-where an equal resistance to the wedge ABC, dividing its parts AF and BG, then the power of the wedge would be to the resistance of the wood as their velocities inversely, that is, as the spaces moved through in the same time, that is, as the height of the wedge HC to half its width AH.

WEDNESDAY, the fourth day of the week, so called from a Saxon idol named Woden, supposed to be Mars, worshipped on this day.

Asb **WEDNESDAY**, the first day of Lent, so called from the custom observed in the ancient christian church of penitents expressing their humiliation at this time, by appearing in sack-cloth and ashes. The want of this discipline is at present supplied, by reading publicly on Ash-wednesday the curses denounced in Scripture against the several sorts of sins, the people repeating after each curse, Amen.

WEED, a common name for all rank and wild herbs, that grow of themselves, to the detriment of other useful herbs they grow among.

The farmer finds it impossible ever wholly to destroy the weeds in his lands; and the reason seems to be, that in many kinds the seeds will lie many years in the ground, and successively grow, some one year and some another; so that the destroying the crop entirely, for one year, does not kill them for succeeding ones. The seed of red-poppy

This image shows a blank, aged, cream-colored page, likely an endpaper or flyleaf of a book. The paper has a slightly textured appearance with some faint smudges and discoloration, characteristic of old paper. The left edge of the page is bound, showing the stitching and the inner cover material. There is no text or other markings on the page.

W E I

poppy will lie twenty years in the ground, in a land all that time occupied by saintfoin; and, if it be, after that, plowed for corn, they will all grow, and fill the field.

The seeds of these plants will never all come up in one year, because they must have their exact degrees of depth, moisture, and covering; the seeds which want any of these one year, lie to grow up another. The best defence the farmer has hitherto found against these enemies, is to endeavour their destruction by a summer fallow. This, if the weather be propitious, does make some havoc among them, but it never destroys them entirely. If the seeds lie so high that the summer's heat parches them up, or so deep that it cannot reach them, they do not germinate, and are by that means saved for another year. And another thing which saves a very great number of them, is their being able to bear the heat and moisture of the whole year without growing. Wild oats, and many other seeds of weeds, are of this kind. If you gather these when ripe, and sow them in the most careful manner, watering them at times, and taking all the care of them that is necessary to the most tender plants, they will not grow till the spring come twelve-months after they were sowed, and sometimes not till the spring after that; that is, two years and a half after the time of putting them into the ground. It is plain from this, that no art can destroy these by fallowing, or other means, in one year.

The common way of weeding among the young corn turns out to very little good; if this is done while the weeds are young, the greatest part of them are only cut or broken off near the ground; this, instead of destroying them, gives them new vigour, and they shoot up with many heads in the place of one, and draw more nourishment than at first: if, on the other hand, it is done when they are grown up, the relief comes after the disease; for by that time they have robbed the corn of all the nourishment, or nearly all, they could. Hand-weeders also frequently do more harm in the corn by treading it down, than they do good by taking out the weeds. This operation sometimes costs the farmer twelve shillings an acre, besides the mischief done, and yet there remain weeds enough for a crop the next year from seeds.

The method of horse-hoeing is a very excellent way of curing lands of this disease, so long as it is carefully practised; one of the greatest advantages it will bring the farmer is, that no weeds will grow up but those whose seeds are brought in the air, and these are but very few in comparison of the other kinds.

WEEDS, in mining, a term used by our English diggers to express any sort of unprofitable substance found among the ores of metals. They seem to have borrowed the phrase from the gardeners; and as every thing with them is a weed, except what they have planted, and expect to gather; so every thing is a weed with the miners, except the thing they are sinking for.

The principal substances known in our mines under the names of weeds, are mundic or marcasite; this is of three sorts, white, yellow, and green; daze, a kind of glittering talcy stone, of the telaugium kind, which endures the fire, and is of various colours and hardnesses; iron-moulds or pyritæ; caul, which is brownish and spungy; and glister, which is a sort of talc.

WEEK, *Septimana, hebdomada*, in chronology, a division of time comprising seven days.

The origin of this division of weeks, or of computing time by sevenths, is greatly controverted. Some will have it to take its rise from the four quarters or intervals of the moon, between her changes or phases, which, being about seven days distant, gave occasion to the division.

Be this as it will, the division is certainly very ancient. The Syrians, Egyptians, and most of the oriental nations, appear to have used it from all antiquity: though it did not get footing in the west till Christianity brought it in: the Romans reckoned their days not by sevenths but by ninths, and the ancient Greeks by decads or tenths.

Indeed, the Jews divided their time by weeks, but it was upon a different principle from the eastern nations, God himself appointing them to work six days, and to rest the Sabbath, in order to keep up the sense and remembrance of the creation; which being effected in six days, he rested the seventh.

Passion WEEK, or the *Holy WEEK*, is the last week in Lent, wherein the church celebrates the mystery of our Saviour's death and passion.

WEIGH, WAY, or WEY, *waga*, a weight of cheese, wool, &c. containing 256 pounds avoirdupoise. Of corn, the weigh contains 40 bushels; of barley or malt, six quarters. In some places, as Essex, the weigh of cheese is 300 pounds.

WEIGHER, an officer in divers cities appointed to weigh the commodities bought or sold in a public balance.

WEIGHING, the act of examining a body in the balance to find its weight.

WEIGHING-CHAIR, a machine contrived by Sanctorius, to determine the quantity of food taken at a meal, and to warn the feeder when he had his quantum.

WEIGHING-ANCHOR, is the drawing it out of the ground it had been cast into, in order to set sail, or quit a port, road, or the like.

WEIGHT, GRAVITY, *Pondus*, in physics, a quality in natural bodies whereby they tend downwards, towards the center of the earth. Or, weight may be defined, in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the center of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare.

In the common use of language, weight and gravity are considered as one and the same thing. Some authors, however, make a difference between them; and hold gravity only to express a nifus or endeavour to descend, but weight an actual descent. But there is room for a better distinction. In effect, one may conceive gravity to be the quality as inherent in the body; and weight the same quality, exerting itself either against an obstacle, or otherwise. Hence, weight may be distinguished, like gravity, into absolute and specific. See GRAVITY.

Sir Isaac Newton demonstrates, that the weights of all bodies, at equal distances from the center of the earth, are proportionable to the quantities of matter each contains. Whence it follows, that the weights of bodies have not any dependence on their forms, or textures; and that all spaces are not equally full of matter. Hence, also, it follows, that the weight of the same body is different on the surface of different parts of the earth; by reason its figure is not a sphere, but a spheroid.

WEIGHT, *Pondus*, in mechanics, is any thing to be raised, sustained, or moved by a machine, or any thing that in any manner resists the motion to be produced.

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the ballance against other bodies, whose weight is required.

The security of commerce depending, in good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations have taken care to prevent the falsification thereof, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus, in England, the standard of weights is kept in the Exchequer, by a particular officer called the clerk of the market.

Weights may be distinguished into ancient and modern, foreign and domestic.

Ancient WEIGHTS. 1. Those of the ancient Jews, reduced to the English troy weights, will stand as in the following table:

	lb.	oz.	dwt.	gr.
Shekel — — — — —	00	00	09	02 $\frac{1}{2}$
60 Manch — — — — —	02	03	06	10 $\frac{2}{7}$
3000 50 Talent — — — — —	113	10	01	10 $\frac{2}{7}$

2. Grecian and Roman weights, reduced to English troy weight, will stand as in the following table :

										oz. dwt. gr.		
Lentes -----										00	00	$\frac{8\frac{1}{2}}{1\frac{1}{2}}$
4	Siliquæ -----									00	00	$03\frac{1}{2}$
12	3	Obolus -----								00	00	$09\frac{3}{4}$
24	6	2	Scriptulum -----							00	00	$18\frac{3}{4}$
72	18	6	3	Drachma -----						00	00	$06\frac{6}{14}$
96	24	8	4	$1\frac{1}{3}$	Sextula -----					00	03	$00\frac{6}{7}$
144	36	12	6	2	$1\frac{1}{2}$	Sicilicus -----				00	04	$13\frac{2}{7}$
192	48	16	8	$2\frac{2}{3}$	2	$1\frac{1}{3}$	Duella -----			00	06	$01\frac{5}{7}$
576	144	48	24	8	6	4	3	Uncia -----		00	18	$05\frac{1}{7}$
6912	1728	576	288	96	72	48	36	12	Libra 10 18		$13\frac{5}{7}$	

The Roman ounce is the English avoirdupois ounce, which they divided into seven denarii, as well as eight drachms ; and since they reckoned their denarius equal to the Attic drachm, this will make the Attic weights one eighth heavier than the corresponding Roman weights.

Modern European WEIGHTS. 1. English weights. By the twenty-seventh chapter of Magna Charta, the weights all over England are to be the same ; but for different commodities, there are two different sorts, viz. troy weight and avoirdupoise weight. The origin from which they are both raised, is a grain of wheat gathered in the middle of the ear.

In troy weight, twenty-four of these grains make a penny-weight sterling ; twenty penny-weights make one ounce ; and twelve ounces one pound.

By this weight we weigh gold, silver, jewels, grains, and liquors. The apothecaries also use the troy pound, ounce, and grain ; but they differ from the rest in the intermediate divisions. They divide the ounce into eight drachms ; the drachm into three scruples, and the scruple into twenty grains.

In avoirdupoise weight, the pound contains sixteen ounces, but the ounce is less by near one-twelfth than the troy ounce ; this latter containing 490 grains, and the former only 448. The ounce contains 16 drachms. 80 ounces avoirdupois are only equal to 73 ounces troy ; and 17 pounds troy equal to 14 pounds avoirdupoise. See AVOIRDUPOISE.

By avoirdupoise weight are weighed mercury, and grocery wares, base metals, wool, tallow, hemp, drugs, bread, &c.

Table of troy weight as used by the Goldsmiths. Apothecaries.

Grains				Grains.			
24	Penny-weight			20	Scruple		
480	20	Ounce		60	3	Drachm	
5760	240	12	Pound	480	24	8	Ounce
				5760	288	96	Pound

Table of avoirdupoise weight.

Scruples				Grains.			
3	Drachm			20	Scruple		
24	8	Ounce		60	3	Drachm	
384	128	16	Pound	480	24	8	Ounce
43008	14336	1792	112 Quintal, or Hundred	5760	288	96	Pound
860100	286720	35840	2240 20 Ton				

The moneyers, jewellers, &c. have a particular class of weights, for gold and precious stones, viz. carat and grain ; and for silver, the penny-weight and grain.

The moneyers have also a peculiar subdivision of the grain troy : thus,

The {	Grain	Mite	Droit	Perit	}	into {	20 Mites
							24 Droits
							20 Perits
							24 Blanks.

The dealers in wool have likewise a particular set of weights, viz. the sack, weigh, tod, stone, and clove.

2. French weights : the common or Paris pound is 16 ounces ; which they divide two ways : the first division is into two marcs ; the marc into 8 ounces ; the ounce into 8 gros ; the gros into 3 penny-weights ; the penny-weight into 24 grains ; the grain equal to a grain of wheat. The second division of the pound is into 2 half pounds ; the half pound into 2 quarters ; the quarter into 2 half quarters ; the half quarter into 2 ounces ; and the ounce into 2 half ounces.

The weights of the first division are used to weigh gold, silver, and the richer commodities ; and the weights of the second division, for commodities of less value.

Grains

24	Penny-weight		
72	3	Gros	
576	24	8	Ounce
4608	192	64	8 Marc
9216	384	128	16 2 Pound.

Half ounce

2	Ounce		
4	2	Half-quarter pound	
8	4	2	Quarter pound
16	8	4	2 Half pound
32	16	8	4 2 Pound
3200	1600	800	400 200 100 Quintal.

But the pound is not the same throughout France. At Lyons, the city pound is only 14 ounces ; so that 100 Lyons pounds make only 88 Paris pounds. But beside the city pound, they have another at Lyons for silk, containing 16 ounces. At Thoulouse, and throughout the Upper-Languedoc, the pound is 13 ounces and a half of Paris weight. At Rouen, beside the common Paris pound and marc, they have the weight of the vicomte ; which is 16 ounces, a half, and five-sixths of the Paris weight.

The weights, enumerated under the two articles of English and French weights, are the same that are used throughout the greatest part of Europe ; only under somewhat different names, divisions, and proportions.

Particular nations have also certain weights peculiar to themselves : Thus Spain has its arrobas, containing 25 Spanish pounds, or one-fourth of the common quintal : its quintal macho, containing 150 pounds, or one-half common quintal, or 6 arrobas : its adarme, containing one-sixteenth of its ounce. And for gold, it has its castellan, or one-hundredth of a pound ; its tomin, con-

containing 12 grains, or one-eighth of a castellan. The same are in use in the Spanish West-Indies.

Portugal has its arroba, containing 32 Lisbon arratels, or pounds. Savary also mentions its faratelle, containing 2 Lisbon pounds; and its rottoli, containing about 12 pounds. And for gold, its chego, containing four carats. The same are used in the Portuguese East-Indies.

Italy, and particularly Venice, have their migliaro, containing four mirres; the mirre, containing 30 Venice pounds; the faggio, containing a sixth part of an ounce.

Genoa has five kinds of weights, viz. large weights, whereby all merchandizes are weighed at the custom-house: cash-weights for piaftres, and other species: the cantara, or quintal, for the coarsest commodities; the large balance for raw silks; and the small balance for the finer commodities. Sicily has its rotollo, 32 and a half pounds of Messina.

Germany, Flanders, Holland, the Hanse-Towns, Sweden, Denmark, Poland, &c. have their schippont, which at Antwerp and Hamburg, is 300 pounds; at Lubeck, 320; and at Coningsberg, 400 pounds. In Sweden, the schippont for copper is 320 pounds; and the schippont for provisions 400 pounds. At Riga and Revel, the schippont is 400 pounds; at Dantzic, 340 pounds; in Norway, 300 pounds; at Amsterdam, 300; containing 20 lyspondts, each weighing 15 pounds.

In Muscovy, they weigh their large commodities by the bercherock, or berkewits, containing 400 of their pounds. They have also the poet, or poede, containing 40 pounds, or one-tenth of the bercherock.

In order to shew the proportion of the several weights used throughout Europe, we shall add a reduction of them to one standard, viz. the London and Amsterdam pound.

1. Proportion of the weights of the principal places of Europe.

The 100 lb. of England, Scotland, and Ireland are equal to

lb. oz.	
91	8 of Amsterdam, Paris, &c.
96	8 of Antwerp or Brabant.
88	0 of Rouen, the viscounty weight.
106	0 of Lyons, the city weight.
90	9 of Rochelle.
107	11 of Toulouse and Upper Languedoc.
113	0 of Marseilles or Provence.
81	7 of Geneva.
93	5 of Hamburg.
89	7 of Francfort, &c.
96	1 of Leipzig, &c.
137	4 of Genoa.
132	11 of Leghorn.
153	11 of Milan.
152	0 of Venice.
154	10 of Naples.
97	0 of Seville, Cadiz, &c.
104	13 of Portugal.
96	5 of Liege.
112	$\frac{2}{3}$ of Russia.
107	$\frac{1}{4}$ of Sweden.
89	$\frac{1}{2}$ of Denmark.

2. Proportion of the weights of the chief cities in Europe to those of Amsterdam.

An 100 pounds of Amsterdam are equal to

lb.	
108	of Alicant.
105	of Antwerp.
120	of Archangel, or 3 poedes.
105	of Arschot.
120	of Avignon.
98	of Basil in Switzerland.
100	of Bayonne in France.
166	of Bergamo.
97	of Bergen-op-zoom.
95 $\frac{1}{4}$	of Bergen in Norway.
111	of Bern.
100	of Befançon.
100	of Bilboa.

lb.

105	of Bois le duc.
151	of Bologna.
100	of Bourdeaux.
104	of Bourgen Bresse.
103	of Bremen.
125	of Breslaw.
105	of Bruges.
105	of Brussels.
105	of Cadiz.
105	of Cologne.
125	of Coningsberg.
107 $\frac{1}{2}$	of Copenhagen.
87	rottos of Constantinople.
113 $\frac{1}{2}$	of Dantzic.
100	of Dort.
97	of Dublin.
97	of Edinburgh.
143	of Florence.
98	of Francfort on the Maine.
105	of Ghent.
89	of Geneva.
163	of Genoa, cash weight.
102	of Hamburg.
106	of Leyden.
105	of Leipzig.
105 $\frac{1}{2}$	of Liege.
114	of Lisle.
143	of Leghorn.
106 $\frac{1}{2}$	of Lisbon.
109	of London, avoirdupoise weight.
105	of Louvaine.
105	of Lubec.
141 $\frac{1}{2}$	of Lucca, light weight.
116	of Lyons, city weight.
114	of Madrid.
105	of Marlines.
123 $\frac{1}{2}$	of Marseilles.
154	of Messina, light weight.
168	of Milan.
120	of Montpelier.
125	bercherocks of Muscovy.
100	of Nantes.
106	of Nancy.
169	of Naples.
98	of Nuremberg.
100	of Paris.
112 $\frac{1}{2}$	of Revel.
109	of Riga.
100	of Rochelle.
146	of Rome.
100	of Rotterdam.
96	of Rouen, viscounty weight.
100	of St. Malo.
100	of St. Sebastian.
158 $\frac{1}{2}$	of Saragosa.
106	of Seville.
114	of Smyrna.
110	of Stetin.
81	of Thouloufe and Upper Languedoc.
151	of Turin.
158 $\frac{1}{2}$	of Valencia.
182	of Venice, small weight.

WEIGHTS used in the several parts of Asia, the East-Indies, China, Persia, &c. In Turkey, at Smyrna, &c. they use the batman, or battemant, containing six occos; theocco weighing three pounds four-fifths English. They have another batman much less, consisting as the former, of six occos; but theocco only containing fifteen ounces English: 44 occos of the first kind make the Turkish quintal. At Cairo, Alexandretta, Aleppo, and Alexandria, they use the rotto, rotton, or rottoli. The rottoli at Cairo, and other parts of Egypt, is 144 drachms; being somewhat over an English pound. At Aleppo there are three sorts of rottos; the first, 720 drachms, making about 7 English pounds, and serving to weigh cotton, galls, and other large commodities; the second is 624 drachms, used for all silks but white ones, which are weighed by the third rotto of 700 drachms. At Seyda the rotto is 600 drachms.

The other ports of the Levant, not named here, use some of these weights; particularly the *occo*, or *ocqua*, the *rottoli*, and *rotto*.

The Chinese weights are, the piece, for large commodities; it is divided into 100 *catis*, or *cattis*: tho' some say, into 125; the *cati* into 16 *taels*, or *tales*; each *tael* equal to $1\frac{1}{3}$ of an English ounce, or the weight of 1 *rial* and $\frac{1}{2}$, and containing 12 *mas*, or *masses*, and each *mas* 10 *condrins*. So that the Chinese piece amounts to 137 English pounds *avoirdupois*, and the *cadi* to 1 pound 8 ounces. The *picol* for silk, containing 66 *catis* and $\frac{3}{4}$; the *bahar*, *bakaire*, or *barr*, containing 300 *catis*.

Tonquin has also the same weights, measures, &c. as China. Japan has only one weight, viz. the *cati*; which, however, is different from that of China, as containing twenty *taels*.

At Surat, Agra, and throughout the states of the great mogul, they use the *man*, or *maund*, whereof they have two kinds; the king's *man*, or king's weight; and the *man* simply; the first used for the weighing of common provisions, containing forty *seers*, or *serres*; and each *seer* a just Paris pound. The common *man* used in the weighing of merchandize, consists likewise of 40 *seers*, but each *seer* is only estimated at 12 Paris ounces, or $\frac{3}{4}$ of the other *seer*.

The *man* may be looked upon as the common weight of the East-Indies, though under some difference of name, or rather of pronunciation; it being called *mao* at Gambaya, and in other places *mein*, and *maun*. The *seer* is properly the Indian pound, and of universal use: the like may be said of the *bahar*, *tael*, and *catti*, above-mentioned.

The weights of Siam, are, the piece, containing 2 *shans*, or *cattis*; but the Siamese *catti* is only half the Japanese; the latter containing 20 *taels*, and the former only 10: though some make the Chinese *catti* only 16 *taels*, and the Siamese 8. The *tael* contains four *baats* or *ticals*; each about a Paris ounce; the *baat* 4 *selings*, or *mayonnes*; the *mayon* 2 *fouangs*; the *fouang* 4 *payes*; the *paye* 2 *clams*; the *sompaye* $\frac{1}{2}$ *fouang*.

It is to be observed, that those are the names of their coins as well as weights; silver and gold being commodities there sold, as other things, by their weights.

In the Isle of Java, and particularly at Bantam, they use the *gantam*, which amounts to near three Dutch pounds.

In Golconda, at Visapour, and Goa, they have the *furatelle*, containing 1 pound 14 ounces English; the *mangalis*, or *mangelin*, for weighing diamonds and precious stones; weighing at Goa 5 grains, at Golconda, &c. $5\frac{1}{2}$ grains. They have also the *rotola*, containing $14\frac{1}{2}$ ounces English; the *metricol*, containing the sixth part of an ounce; the *wall*, for *piastres* and *ducats*, containing the seventy-third part of a *rial*.

In Persia, they use two kinds of *batmans*, or *mans*; the one called *cahi*, or *cheray*, which is the king's weight; and the other, *batman* of Tauris. The first 13 pounds 10 ounces English; the second, $6\frac{1}{2}$ pounds. Its divisions are, the *ratel*, or a 16th; the *derhem*, or *drachm*, which is the 50th; the *meschal*, which is half the *derhem*; the *dung*, which is the 6th part of the *meschal*, being equal to six carat grains; and, lastly, the grain, which is the fourth part of the *dung*. They have also the *vakie*, which exceeds our ounce a little; the *sah-cheray*, equal to the 1170th part of the *derhem*; and the *toman*, used to weigh our large payments of money, without telling; its weight is that of fifty *abassis*.

African and American weights. We have little to say as to the weights of America; the several European colonies there making use of the weights of the states or kingdoms they belong to. For, as to the *aroue* of Peru, which weighs 27 pounds, it is evidently no other than the Spanish *arroba*, with a little difference in the name.

As to the weights of Africa, there are few places that have any, except Egypt, and the countries bordering on the Mediterranean; whose weights have been already enumerated among those of the ports of the Levant. The Island of Madagascar, indeed, has weights, but none

that exceed the *drachm*, nor are they used for any thing but for gold and silver.

WEIGHT of the Air. See AIR.

WELD, or WOLD, in botany, the name of a plant much used by the dyers to give a yellow colour to woollens, silks, cotton, and thread.

Its root, which is composed of a few ligneous fibres, does not pierce deep; from this root it puts forth leaves about four inches long, and half an inch broad, of a lively green, soft to the touch, and spread circularly near the ground, with some gentle wavings at their edges, but obtuse at their points. Its stem, which rises from amidst these leaves to the height of three feet, or even more if the soil and culture be very good, often branches out, and is garnished with leaves like those below, though smaller in proportion as they approach the flowers, which grow in long loose spikes at the end of the branches or stem. These flowers, which appear at the latter end of June, are each of them composed of three small irregular petals of a greenish yellow, to which succeeds a globular berry of the same colour, terminated by three points, and in which are inclosed small brown spherical seeds. These seeds ripen in September. The plant becomes entirely yellow when it is dry, and the whole of it, but especially the berry, is used in dying. The slenderest weld, and particularly if it inclines to a russet colour, is accounted the best: that which is larger, and of a dull green, is much less esteemed.

This plant grows naturally along the sides of highways, upon dry banks, and on old walls, in many parts of England, France, Spain, and other countries where the winters are not very severe; but the cultivated sort is far preferable to the wild, both for the quantity and the goodness of the colour which it yields. It will thrive tolerably on almost any soil, provided it be dry and warm: but the richer the land is upon which it is sown, the greater will be the produce; and in proportion to the care with which it is cultivated, the more vigorous and fit for dying will it be.

The ground for this, as for every other plant, should be in fine tilth at the time of sowing it; though here, unless it be very poor indeed, it will not require dung. The seed should be that of the preceding year; for if it be older, great part of it will not grow. Both Mr. Worlidge and M. Du Hamel are of opinion that weld seed should, on account of its smallness, for it is but little bigger than that of purslane, be mixed with ashes, buckwheat, oats, or some other similar ingredient, in order the better to avoid sowing it too thick: for the plants of weld thrive best when they are about six inches asunder. For this reason, as was before observed in regard to all plants which require being hoed, it is best to sow weld in rows. Some sow it on barley, or oats after they have been sown and harrowed, this requiring only a bush to be drawn over it; for it should not be covered deep. A gallon of weld-seed thus used in the broad cast way will be sufficient to sow an acre of land. It will not grow much during the first summer, when it is thus sown; but it will thrive apace after the corn is taken off.

The beginning or middle of August is a proper season for sowing weld in this country. The only care that it requires whilst growing, is to keep it clear of weeds which might choak it, or at least weaken its growth.

The French, in general, sow their weld in March, and pull it up in July or August of the ensuing year, when part of its seeds are ripe, and the plant is still of a greenish yellow: they then dry it and thresh it upon cloths, to get the ripest of the seed, and after this they tie the stalks up in bundles, and sell them to the dyers. But Mr. Miller rightly judges, that the best time to pull the weld for use is when it begins to flower, that is to say, about the latter end of June, because, like all other vegetables, it is then in its greatest vigour, and consequently best fitted to yield the greatest quantity of dye. For a produce of new seeds, it is much better to sow a small piece of land on purpose, or to set apart for this end a suitable portion of the field of which the plants are intended for use, rather than let the whole stand too long, that is to say, till part of the seeds are ripe; because, by letting the plants

plants stand till then, their quality is injured far beyond the value of the seeds that are got from them (the berries being, as was observed before, the part which yields the finest dye); and besides the seeds thus obtained will of course be a mixture of ripe and half-ripe ones, on the growing of which there cannot be a due reliance. The common way of drying these plants is to set them upright in small handfuls in the field, and when they are dry, to tie them up in bundles. They must also be housed dry; and care must be taken to stack them so loosely that there may be room for the air to pass between them, to prevent their fermenting.

The plants which are intended for seed should be pulled as soon as their seeds are ripe, and then dried and beaten out for use: for if this is deferred, or if they are left stand too long, the seeds will scatter.

The method of cultivating this plant at Oissel, in Normandy, where great quantities of it are raised for exportation to Holland, independent of the consumption in France, is thus related by M. Dambourney, in the Memoirs of the Royal Society of Agriculture at Rouen.

"In the month of July, just after the kidney beans then in bloom have been hoed for the second time, and earthed up, especially if there be an appearance of approaching rain, weld-seed is sown among them, very thin, as equally as possible. Careful husbandmen bury this seed by dragging over it a small bush of thorns. Whilst the weld rises, the beans ripen and are gathered; after which the ground remains, of course, planted with weld only. This is hoed about Michaelmas, then left in that condition during the winter, and in the ensuing month of March, when the danger of frosts is judged to be over, it is hoed again, to extirpate such weeds as may have come up in the mean time. Towards the end of June in this second year, when the weld has done blossoming, when its berries form, and when the plant begins to turn yellow, advantage is taken of the first fair day after a rainy one, to pull it up. Two men will then pull up as much of it in one day, as four men can when the ground is dry and hard. It is carried off in large bundles: but these are untied before the weld is laid up for keeping, and the plants are spread out and set upright against walls or hedges well exposed to the sun, the heat of which completes their drying in two days. They are then laid upon a cloth to prevent the loss of the seed, which drops very easily out of the now open capsules; and finally, after being tied up again in bundles weighing about thirty-pounds a-piece, they are piled up loosely in a barn or other well covered place, where they complete their ripening, and generally shrink to less than half of their former weight.

"Weld raised on rich ground is apt to be greasy and too full of stalks: that which grows in sandy places is of a better quality, and has only one main stem: but, in return, the produce here is much less than in the former case.

"As soon as the weld has been pulled, sheep are turned in upon the land, to eat up the grass it may have produced: it is then plowed once; and after another plowing at the end of October, it is sowed with wheat, or great rye, without using any other compost or dung. If the land is light and destined for spring-corn, turnips may be sown upon the first plowing after the weld; for they will have time to grow big enough to be pulled before the plowing for oats or small rye, which last crops it will be proper to help with a little shavings or raspings of horn.

"If it be intended to raise weld after peas, the ground should be plowed, and the seed sown very thin: to do which the more effectually, this seed, like that of turnips, should be taken up only in pinches between the middle finger and the thumb, and the fore-finger should remain extended, the better to help its spreading when it is dropped. This seed should be sown in rows sufficiently distant for the plants to have full room to grow; and the best way is to leave an alley after every third row. When sown, it is harrowed in, and the only farther care that the weld requires is to keep the plants free from weeds, by hoeing the ground at Michaelmas and in March, as before directed.

"The weld which is sown after peas does not injure the land it grows on; and therefore in this case, as after the kidney-beans before spoken of, wheat may be sown in October, without any previous manure."

WELDING HEAT, in smithery, a degree of heat given to iron, &c. sufficient only for bending, or doubling it up.

WELL, a hole under ground, usually of a cylindrical figure, and walled with stone, brick, &c. and mortar: its use is to collect the water of the strata around it.

The rising of water in wells is thus accounted for. Suppose a well be sunk at the foot of a hill to such a depth as will bring the diggers to an eruption of a spring, whose water is brought by a duct from a cavity in the hill, or otherwise from a pond, a river, the sea, &c. it is evident the water in the well will rise from the bottom to an altitude, where the surface of the water is upon a level with that in the reservoir, and thus constitutes a well. See plate CXXII. fig. 10. where E represents the mouth of the well.

If those reservoirs of water in the body of mountains be situated where mineral ores abound, or the ducts or feeding streams run through mineral earth, it is easy to conceive the particles of metal will mix with, and be absorbed by the water, which being saturated therewith, becomes a mineral spring or well. If salt, sulphur, lime-stone, &c. abound in the strata, through which the water passes, it will then be saline, sulphureous, lime-water, &c. If sulphur and iron should both abound in the parts of the hill, whence the waters come, the waters will partake of the warmth or heat, which is occasioned by the mixture of two such substances in the earth, where they are found. Now, though every thing may not happen precisely in the manner as here represented, yet that it is in some way analogous to it, we believe no person will doubt, who has been at the Peak in Derbyshire, or at Wookey-Hole in Somersetshire, and seen the wonderful caverns, receptacles and streams of water, which nature has there furnished in the bowels of the mountains.

WELL, in the military art, a depth which the miner sinks under ground, with branches or galleries running out from it; either to prepare a mine, or to discover and disappoint the enemy's mine.

WELL-HOLE, in building, is the hole left in a floor for the stairs to come up through. See **STAIRS**.

WEN, a tumour or excrescence that arises on different parts of the body, and contains a cystus, or bag filled with some peculiar matter, of which physicians reckon three kinds, viz. when this matter is soft, resembling pulp, the wen is called atheroma; if like honey, meliceris; and if like suet, steatoma. See the articles **TUMOUR**, **ATHEROMA**, &c.

WERE, in our old law-books, denotes a sum paid for killing a person, when such crimes were punished with pecuniary mulct, and not death.

WERELADA, among our Saxon ancestors, the denying an homicide on oath, in order to be quit of the fine called **WERE**.

WERGILD, or **WEREGELD**, in our ancient customs, the price of a man's head: a part of which was paid to the king, for the loss of his subject, a part to the lord whose vassal he was, and a part to the nearest relation of the person slain.

WEST, in cosmography, one of the cardinal points of the horizon, diametrically opposite to the east; and strictly defined, the intersection of the prime vertical with the horizon, on that side the sun sets in. See **HORIZON**.

In astronomy, west is chiefly used for the place in, or towards which, the sun or stars sink under the horizon. Thus we say, the sun, Mars, &c. are in the west. The point the sun sets in, when in the equator, is particularly called, the equinoctial west, or point of true west. See **EQUINOCTIAL**.

In geography, west and western, are applied to several countries, &c. situate towards the point of sun-setting, with respect to certain others. Thus the Roman empire was anciently, and the German empire is at present, called

called the empire of the west, or the western empire, in opposition to that of Constantinople, which is called the eastern empire.

The Roman church is called the western church in opposition to the Greek church. The Italians, French, Spaniards, &c. are called western nations, in respect to the Asiatics; and part of America, the West-Indies, in respect to the East-Indies.

WHALE, *Balæna*, in zoology, a genus of fishes, distinguished by having certain laminæ, of a horny substance, in the upper jaw, which supply the place of teeth, and usually no fin upon the back: to this it may be added, that the fistula, or aperture, for the discharge of water, is double, and situated either on the forehead, in the middle of the head, or in the rostrum.

The *balæna* with the fistula in the middle of the head, and the back ridged towards the tail, is the fish determinately and properly called the whale, though the *physeter*, as well that with the upper jaw longest, and with a long spine on the back, as that with the back-fin very tall, and the summit of the teeth plane, is the former called the crooked tooth whale, and the latter the plane tooth whale; as is also that *physeter* which is a species of the *balæna*.

The *balæna*, or the whale properly so called, grows to a monstrous size; the head is extremely large, and of an irregular figure, the lower jaw is much larger than the upper, and covers it at the sides; the upper is narrow and oblong, the fistula is double, or has two distinct apertures, and is situated in the middle of the head, between the eyes; the eyes are very small in proportion to the enormous bulk of the head, and are placed a great distance from one another; the whole head is somewhat depressed, and has several irregularities on its surface; the body is very thick, and somewhat rounded, but towards the extremity of the back, there is a subacute angle, extending itself longitudinally to the tail; the tail is somewhat forked, very large, and in its horizontal situation makes a very singular figure. This is an inhabitant of the most northern seas, the principal object of the Greenland fishery, and the first known species.

WHALE-Fishery. — Whales are chiefly caught in the North sea: the largest sort are found about Greenland, or Spitzbergen. At the first discovery of this country, whales not being used to be disturbed, frequently came into the very bays, and were accordingly killed almost close to the shore, so that the blubber being cut off was immediately boiled into oil on the spot. The ships in these times, took in nothing but the pure oil and the fins, and all the business was executed in the country, by which means a ship could bring home the product of many more whales than she can according to the present method of conducting this trade. The fishery also was then so plentiful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the situation of this trade. The ships coming in such numbers from Holland, Denmark, Hamburg, and other northern countries, all intruders upon the English, who were the first discoverers of Greenland, the whales disturbed, and gradually, as other fish often do, forsaking the place, were not to be killed so near the shore as before, but are now found, and have been so ever since, in the openings and spaces among the ice, where they have deep water, and where they go sometimes a great many leagues from the shore.

The whale-fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away and get clear of the ice by the end of August; so that in the month of September at farthest, they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows. As soon as the fishermen hear the whale blow, they cry out *fall! fall!* and every ship gets out its long boat, in each of which there are six or seven men: they row till they come pretty near the whale, then the harpooner strikes it with his harpoon. This requires great dex-

terity, for through the bone of his head there is no striking, but near his spout there is a soft piece of flesh, into which the iron sinks with ease. As soon as he is struck, they take care to give him rope enough, otherwise, when he goes down, as he frequently does, he would inevitably sink the boat: this rope he draws with such violence, that, if it were not well watered, it would by its friction against the sides of the boat, be soon set on fire. The line fastened to the harpoon is six or seven fathoms long, and is called the fore-runner: it is made of the finest and softest hemp, that it may slip the easier: to this they join a heap of lines of 90 or 100 fathoms each, and when there are not enough in one long-boat, they borrow from another. The man at the helm observes which way the rope goes, and steers the boat accordingly, that it may run exactly out before; for the whale runs away with the line with so much rapidity, that he would upset the boat, if it were not kept straight. When the whale is stuck, the other long-boats row before, and observe which way the line stands, and sometimes pull it; if they feel it stiff, it is a sign the whale still pulls in strength; but if it hangs loose, and the boat lies equally high before and behind upon the water, they pull it in gently, but take care to coil it so, that the whale may have it again easily if he recovers strength: they take care, however, not to give him too much line, because he sometimes entangles it about a rock, and pulls out the harpoon. The fat whales do not sink as soon as dead, but the lean ones do, and come up some days afterwards.

As long as they see whales, they lose no time in cutting up what they have taken, but keep fishing for others; when they see no more, or have taken enough, they begin with taking off the fat and whiskers in the following manner. The whale being lashed along side, they lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which together with the fins is struck off, as soon as he is taken, to keep those extremities above water. On the off side of the whale are two boats to receive the pieces of fat, utensils and men that might otherwise fall into the water on that side. These precautions being taken, three or four men with irons at their feet, to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick, and eight long, which are hauled up at the capstane or windlass. When the fat is all got off, they cut off the whiskers of the upper-jaw with an ax. Before they cut, they are all lashed to keep them firm, which also facilitates the cutting, and prevents them from falling into the sea: when on board, five or six of them are bundled together, and properly stowed, and after all is got off, the carcass is turned adrift, and devoured by the bears, who are very fond of it. In proportion as the large pieces of fat are cut off, the rest of the crew are employed in slicing them smaller, and picking out all the lean. When this is prepared, they stow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in tubs in the hold, cramming them very full and close. Nothing now remains but to sail homewards, where the fat is to be boiled and melted down into train oil.

It were in vain to speak in this place of the advantages that may be derived to Great Britain from the whale fishery. We shall only remark, that the legislature think that trade of so great importance, as to grant a very considerable bounty for the encouragement of it; for every British vessel of 200 tons or upwards, bound to the Greenland-seas on the whale fishery, if found to be duly qualified according to the act, obtains a license from the commissioners of the customs to proceed on such voyage; and on the ship's return, the master and mate making oath that they proceeded on such voyage and no other, and used all their endeavours to take whales, &c. and that all the whale fins, blubber, oil, &c. imported in their ship, were taken by their crew in those seas, there shall be allowed forty shillings for every ton according to the admeasurement of the ship.

WHALE-BONE, or, as it is otherwise called, whale-fins, in commerce, a commodity procured from the

whale, used as stiffening in stays, fans, busks, skreens, &c. What we call whale-bone, or fins, is a horny laminæ in the upper-jaw of the balæna, which supply the place of teeth, but there are none such in the lower jaw. These laminæ are commonly called whiskers, which, split and fashioned, are the whale-bone. The pizzle or genital member of the animal serves likewise for the same purpose.

WHARF, a space on the banks of a haven, creek, or hithe, provided for the convenient loading and unloading vessels upon.

The fee paid for the landing of goods on a wharf, or for shipping them off, is called wharfage, and the person who has the direction and oversight of the wharf, receives wharfage, &c. is called the wharfinger.

WHEAT, *Triticum*, the name of a well known plant, greatly cultivated in many parts of the world, especially in England.

It has been very justly observed by the ancients, as well as moderns, that wheat will grow in almost any part of the world, and that, as it is the plant most necessary to mankind, so it is the most general, and the most fruitful. It thrives not only in temperate climates, but also in very hot, and very cold regions; and, when sown in places where it never grew spontaneously, succeeds as well as where it has been always common. The success of our crops of wheat in America plainly prove this: and in Peru and Chili in particular, where this grain was not known till the Europeans introduced it there, it now produces as large a crop as in most parts of Europe.

Wheat should be sowed in autumn, and always when the ground is moist. In the downs of Hampshire, Wiltshire, and Dorsetshire, farmers begin to sow their wheat in August, if any rain has fallen, and even employ their people to sow one place, while they reap another, if wet weather interrupts them in their harvest: for if the corn is not forward in autumn, so as to cover the ground before winter, it seldom does well on those high dry lands, especially if the ensuing spring prove likewise dry. In low strong lands, some husbandmen think they are in good season, if they get their wheat into the ground by the middle of November; nay, it sometimes is Christmas, or even later, before all their wheat is sown. But this late sown wheat, besides being apt to run too much to straw, especially if the spring be moist, is liable to be thrown out of the ground by frosts.

In general, all wheat succeeds best upon strong soils, especially if they have been well drained, so that the corn lies dry: but as some sorts of this grain thrive better in some soils than in others, it might redound to the public welfare if more particular observations were judiciously made, in regard to each kind, than have hitherto been. The white egg-shell wheat is reckoned best for light lands, and to sow with rye for meslin; because it ripens soonest. It should also be the earliest in the ground. This species is much sown in Essex, upon their hazely brick-earths, or loams; as the red-wheat, and the Poland bearded wheat also is there, and in Hertfordshire upon stiff yellow clays. The white Poland, or pole-rivet wheat has not a hollow straw, and therefore is not so subject to lodge as other corn that has. This kind is particularly fit for lands where the crop is apt to run much to straw.

In Oxfordshire, they have a sort of wheat which they call long coned-wheat, and reckon the best for rank clays. Its straw not being hollow, it is the less liable to lodge; and farmers observe that it is the least apt to be mildewed, or be eaten by birds, from which last it is greatly guarded by its long rough awns; but the flour of it is somewhat coarse. Their white kind of red eared wheat has a white ear and a red grain, and is a very good sort for clayey land. It yields a good crop, and seldom smuts.

In Staffordshire, they reckon the red Lammas or bearded wheat the best for cold lands or stiff clays.

In Berkshire is a wheat called pendulum-wheat, from the hanging of its ear, much like the cone-wheat.

In Northamptonshire, they have a sort of wheat with a white straw and reddish ear and grain; much commended for the plumpness and largeness of the grain, and the

strength of the straw, which prevents its being subject to lodge; nor is it apt to be eaten by birds. They have also a red eared bearded wheat, and a sort of pollard or duck-bill wheat, as it is called, known in Suffex by the name of fuller's wheat, which has so close and thick a husk, that the birds never injure it. Mr. Miller observes that this sort of wheat grows very tall, and, if it be sown too thick, is very apt to be lodged by rain and wind; for that its ears are large and heavy, and incline on one side as the grain increases in weight; but that, if its roots are at a proper distance from each other, it will tiller greatly and have strong stalks, and that the grain of this wheat yields more flour in proportion than that of any other sort. The awns of this wheat always drop off when the grain is full grown.

Smyrna wheat, commonly called many-eared wheat, because several lesser or collateral ears grow around the bottom of the main ear, which is very large in its state of perfection, requires more nourishment than the common husbandry in the large way can give it, and therefore is not cultivated by our farmers: but it would, probably, do extremely well in the horse-hoeing husbandry, where the quantity of food can be enlarged almost at pleasure. For the same reason maiz, commonly called Turkey or Indian corn, is fittest for this last husbandry.

Some gentlemen have been curious enough to procure their seed wheat from Sicily, and it has succeeded very well as to the growth: but the grain of this species has proved too hard for our English mills to grind.

The best time for sowing wheat is about the beginning of September, especially if any rain has fallen; a circumstance so essential, that if the earth be very dry, the farmer had better stay till friendly showers have moistened his soil, than put his corn in ground where it will not grow before it has been wet, let the time be ever so long. Mr. Mortimer says he has known wheat to be so mustied and spoiled by laying long in the ground, before rain came, that it has never grown at all: to which he adds, that he has likewise seen very good crops of wheat from seed sown in July. At all events, the husbandman should certainly have his wheat sowing finished by the middle of October. Whoever neglects this, shews in so doing, a want of proper œconomy in his affairs, and will have cause to repent the delay.

Early sowings require less seed than late ones, because the plants then rise better, and acquire strength to resist the winter's cold. More seed should always be allowed for poor lands than for rich, because a greater number of plants will perish on the former. Rich lands, sowed early, require the least seed of any.

Another circumstance which the husbandman should carefully attend to in sowing, is that his estimate of seed be formed, not from the capacity of any particular measure, but from the number of grains which that measure will contain; because the grains of some growths of wheat are much larger than those from off other lands, tho' of the same species, and perhaps equally good. By not considering this, the ground will of course frequently be sown too thick, or too thin; tho' we believe farmers are seldom apt to run into this last extreme. That they too often commit the former error, so manifestly contrary to their interest in every respect, is demonstrated by reason, and by daily experience:—but neither of these is sufficient to make them deviate from the beaten track. Instead of the usual allowance of three bushels of seed wheat to an acre of land, repeated trials have shewn that half that quantity is generally more than sufficient: consequently a great deal of corn is actually thrown away; for the expence of purchasing seed, which most skilful husbandmen do, at least every other year, amounts to a considerable article in large farms, and in a whole country, merits the attention of the public, especially in scarce years: besides which, the future plants, crowded together by being thus sown too thick, and not having a sufficient space allowed them for their sustenance, cannot yield near so fine and plentiful a crop as they would otherwise produce. A fair trial, made with proper care, would soon convince farmers of their error in this respect; for if they but examine a field of corn sown in the com-

mon way, they will find few plants with more than two or three stalks, unless by chance, where some of them stand so as to have room to spread. These will have six, eight, or ten stalks, and frequently many more: but a field of wheat sown with only a bushel of good corn has been known to be well covered with healthy vigorous plants, each of which has had from six to fourteen, or more, stalks, crowned with long well-nourished ears, full of fine plump grain, of which it has yielded a much greater quantity than any of the neighbouring grounds sown with the common allowance. If the land is good, and the plants stand at a proper distance from each other, few of them will produce less than the above number of stalks and ears. But farmers think they shall have no crop if the ground is not covered with the blades of corn by the spring: whereas, if they would have patience to wait till the plants put out all their stems, they would be amply convinced of the contrary. Every one must have observed in places where foot-paths are made through corn-fields, that, by the side of those paths, where the corn is thin, and has been trodden down in the winter and spring, the plants have stood erect, when most of the corn in the same field has been laid flat upon the ground; an advantage which can proceed from no other cause, than that their stalks are stronger from their having more room: for those of the other plants are drawn up tall and slender by being too close together.

More seed is commonly sowed upon new broke up ground, than upon that which has been longer in tillage. From half an inch to three inches is the usual depth at which wheat is planted, according to the nature of the soil; the stiffest lands requiring the shallowest sowing, as was before observed. The general custom is, to sow it under furrow, which is certainly most advisable if the soil be shallow, to prevent the plants being thrown out by the winter's frosts, or their roots being left bare by the drying winds in the spring. Some sow in broad cast, either with a single cast, or a double bout, harrowing once between; after which the ground is again harrowed several times, till the seed is well covered. However, a great deal of it will become the prey of birds, in this manner of sowing. On the other hand, in planting the corn deep, there is the greater danger of its being eaten off by worms between the grain and the blade.

Great care should be taken to guard against the rooks just at the time when the wheat is shooting up. These mischievous birds perceive its sprouting much sooner than the farmer can, and are led by the shoot to pick it up. They must therefore be carefully kept off the ground for a week or ten days at this season; for at the end of that time the blade will be grown up, and the grain so exhausted of its substance, that they will not give themselves any trouble about stealing it. They never molest the wheat which is sown about Michaelmas; because so much grain of the late harvest then lies scattered about the fields, that they find it easier to pick up that, than to search for corn under ground, in the new-sown lands.

No part of husbandry requires the farmer's attention more than keeping his land free from weeds; yet few trouble themselves much about this essential article, are sensible of its importance, or understand the proper method of doing it: nay, many do not even know which weeds are annual, and which perennial; a distinction highly necessary to be made by every person who would keep his ground clean and in good order, and without which the greatest industry will often be baffled. Annual weeds may be soon destroyed, if taken in time: but if they are neglected, their seeds will ripen, and sow themselves in such abundance, that much additional labour and expence will be required to do that which might have been performed with ease at the beginning, without subjecting the corn to be robbed of its nourishment by bad neighbours. The common method of weeding is very absurd: for in that practice the weeds are left to grow till the wheat begins to ear, and they are in flower; by which means, the ground being covered by the corn, all the low weeds are hid, left to ripen, and scatter their seeds: only the tall weeds are taken out;

and if the people employed are not careful, many of these will escape them, by being so intermixed with the stalks of the wheat, as not instantly to be distinguished. At the same time great numbers of the plants of wheat are broken and trod under foot by the weeder.

To obviate these inconveniences, Mr. Miller recommends the method now practised by good kitchen gardeners, who clear their ground with a small kind of hoe, which, if used among the wheat early in the spring, before the ground is covered by the blades of corn, will effectually eradicate all the weeds, especially if this work be done in dry weather; because, being small, they then soon wither and die. If the ground happens to be very full of weeds, it may be necessary to go over it a second time, about a fortnight after the first, to cut up those which may have been too small to be noticed. By this means the corn will be kept clean, freed from robbers which would deprive it of due nourishment, and there will not be time for new weeds to grow so as afterwards to do it any great prejudice: for the ground will be so much shaded by the corn, that the weeds will thereby be kept down, in such manner as not to ripen their seeds before harvest.

If, at the time of this operation, some of the plants of corn are cut up where they grow too close, the rest will be greatly benefited thereby: but in this, adds Mr. Miller, I fear that few of the old farmers will ever agree with me, though what I mention is not from theory, but from experiments, repeated with great care, and such success that the produce of twenty rods of ground was much greater, both in weight and measure, than that of the same extent in the very best part of the field, where this was not practised; and the stalks of the corn thus thinned stood upright, when a great part of the crop in the same field was lodged.

Both the advantage of having the plants of corn at proper distances from each other, and that of keeping them quite free from weeds, too difficult, not to say almost impracticable, tasks to be completely effected in the common method of sowing, are fully obtained in the New husbandry, as will soon be evidently shewn.

M. Duhamel and Mr. Miller justly blame the practice of those who either turn hogs in among their wheat, to destroy part of it when it grows too thick; or sheep to eat it down, when they think it too rank. The absurdity of the former is self evident: and in regard to the latter, it is well known, from long experience, that the leaves, or blades, of corn are necessary to draw in nourishment from the air and dews, for the increase of the stalk and ear. To be thoroughly satisfied in this, Mr. Miller cut off the leaves of some plants of wheat, alternately, early in the spring, and always found the stalks of these plants much smaller, the ears shorter, and the grain poorer, than those of the intermediate plants whose blades were not cut. Several experiments made by M. Duhamel have proved, not only that all plants are impeded in their growth, and rendered less perfect in their productions, but often even killed, by stripping them of their leaves: and this is confirmed by Mr. Miller, who adds, that he has frequently observed in gardens that plants divested only of their lower leaves, plucked off by ignorant persons upon a supposition of their drawing the nourishment from the head, have been greatly weakened thereby. The same will undoubtedly hold good with respect to corn: besides which, cattle, and particularly sheep, will often bite so close as to destroy the crown of the plant, from whence its future growth should proceed.

Wheat is ripe when its straw is turned yellow, its ears hang, no greenness appears in the middle of them, and the grain is hard when bitten. From four to five quarters is reckoned a good crop: but some would hardly credit how much beyond this the produce of good ground, thoroughly well cultivated, may be increased.—Those who are sensible of the vast advantages of a perfect culture, will not be surprised at Mr. Miller's assuring us that he has known eight and ten quarters, and sometimes more, reaped from an acre, over the whole field, where the corn has stood thin upon the ground; and that he has been informed by persons of great credit,

credit, that even twelve quarters have been reaped from an acre of land drilled and managed with the horsehoe.

Both wheat and rye may be cut somewhat before they are thoroughly ripe, especially if they be lodged; for if the straw be broken, it will no longer convey any nourishment to the grain. M. Duhamel seems to think this even the most eligible way for wheat, because the grain will harden afterwards in the sheaf; whereas, if it be let stand till it is too ripe, it will shed greatly in cutting, binding, and carrying home. It is partly to prevent this inconvenience, that good husbandmen tie it in the evening, and carry it off early the next morning. The ancients reaped their corn before it was full ripe, as Pliny informs us. And indeed it must be allowed that very great disadvantages necessarily attend the letting of some sorts of corn stand till their grains have acquired their utmost maturity. Both the chaff and the fodder are the worse for it; and, if such ripe corn takes wet, the increase in malt is lost, if it be barley, it having already spent itself; and if it be wheat, the quality of the flour is greatly impaired, as well as the quantity considerably lessened. But if corn be cut greenish, it will bear a pretty deal of wet without damage; for it will not imbibe the water like full ripe corn, but only take in so much as to be kindly fed thereby. Again, if any sort of corn be blighted, the sooner it is cut down, though but half ripe, the better it will be; for nourishment can no longer be conveyed to it by the straw; but it will be fed by lying in the ear. The straw would become more and more brittle, by standing till the corn is ripe; and the grain comes the clearer from the husk, when threshed, if this blighted sort be cut early.

One man, with a binder, may reap an acre of wheat and somewhat more of rye, in a day, if the corn stand well: he will also clear about an acre of peas, vetches, &c. in the same space of time.

The husbandman, says M. Duhamel, cannot have a more favourable season to get in his harvest, than that which is afforded him by hot and dry weather: for the quality of the corn is improved, and the grain is rendered much fitter to keep, by the sun's having acted powerfully upon it, either towards the latter part of its standing, or just after it has been cut: though it is true, on the other hand, that this very circumstance renders the ears more apt to shed their grain, and that the value of a sowing is often lost thereby. To prevent this, as much as possible, the corn is first laid in grips, and then tied up in sheaves, in the cool of the evening, or early in the morning before the heat comes on; and the mowers of oats frequently work during part of the night, to avoid the excessively fatiguing sultriness of the noon. These poor people, whose task is infinitely laborious, are liable to many grievous disorders; especially the reapers, who, being obliged to stoop to their work, almost to the very point where the rays of the sun are most violently reflected by the earth, breathe a perfectly burning air. This forces them to drink copiously of liquors, which, being heated by the sun, allay their thirst only for a few moments, and, I strongly suspect, often occasion severe illnesses: the inventing of a machine, engine, or instrument, by which the hardness of this labour might be mitigated, would therefore be a truly useful discovery; and I most heartily exhort all ingenious persons who have a mechanic turn, seriously to think of it.

The two usual ways of cutting corn, are either with the scythe, or with the sickle. The former is commonly used for oats and barley, or, sometimes, for very thin, short wheat; and the sickle is generally appropriated to the reaping of tall and thick wheat and rye. The scythe dispatches so much more work than the sickle, that the difference of expence between reaping an acre, or mowing it, is nearly in the proportion of five to two.

Every part of the mower's body labours and fatigues, and his work requires greater dexterity than that of the reaper: but as the mower is always in a kind of standing posture, he has the advantage of being refreshed by

every breeze of air; which the reaper, for the reasons before-mentioned, has not.

"I do not despair but that some engine may, one time or other, be found out, to ease these very hard labourers, and expedite their work. In the mean time I am persuaded that the following account, written by Mr. Lille, of what himself has practised on his own estate, will afford the reader sufficient satisfaction, and it will be justice to observe, that he does not relate matters of mere speculation, but real facts; things actually executed by himself, and which I should certainly have tried, could I possibly have been in the country when our harvests were got in.

M. de Lille's account of his method of mowing WHEAT.

"When I first put a scythe to my corn, I was of course laughed at by some of my neighbours, because they had never seen any such thing. I let them enjoy their pleasantries; but persevered in my undertaking, which I have now practised sufficiently to be able to point out minutely its advantages, and its inconveniences; for I allow that, though the former are very great and numerous, it is also attended with some of the latter.

"The year 1751 was very rainy, our grass rotted upon the ground, our corn was poor and infested with weeds; and the weather continued extremely bad during all the harvest season. One of my fields of wheat, containing about fifteen acres, was, in particular, in such wretched plight, that I did not think the crop worth taking off. However, after walking over it, and viewing it on every side, I found that the quantity of grass and other growths upon it, might, if mowed, afford a great deal of fodder, which would make me some amends for the total loss of my lucerne. I therefore determined to let my horses have it all, with the little wheat which appeared here and there. This first made me think of mowing a field of wheat; tho' I soon recollected that I had met with the hint before, in some of your writings. Accordingly, I set my mowers to work: my field yielded a great quantity of fodder; the grass, mowed within two inches of the ground, shot up anew, and afforded excellent pasture; and lastly, my bailiff, more saving than I had been, ordered the trusses to be threshed, and got out of them as much wheat as was yielded by other grounds.

"Whilst I was congratulating myself upon the success of my operation, by which my horses and cattle were provided with plenty of fodder for the next winter, I learnt that the husbandmen in Hainault, Flanders, Artois, and other adjacent parts, never cut their corn down otherwise than with a scythe; but at the same time I was informed, that they do not mow wheat in the same manner as oats; that the scythes are not made alike for both these works, and that there are some other essential differences.

"These observations were a sort of proof that the practice had been found to answer, since it was still continued; and I concluded, that if my operation, imperfect as it was, had succeeded so well, I might expect far greater advantages when it should be performed regularly: but, not to be too strongly prejudiced in its favour, I resolved to make a trial upon about thirty acres only.

"By dint of inquiry I found within a few miles of me a husbandman who came from the province of Artois, and had been used to this very business. I talked with him; he told me how the work ought to be done, pointed out its advantages, and I retained him for my intended next year's mowing of wheat; but as the season was pretty far advanced, and there was not time to procure from his country other people equally well acquainted with the practice, to follow the scythe, and to do the whole completely in every respect, he instructed two young lads, as well as he could. In short, nothing was wanting but a mere matter of form, by the neglecting of which some of the lists of the cut corn were misplaced, so that there were ears at both ends of the sheaf.

"I ought not here to forget the clamour raised by this novelty. I made the experiment upon my finest wheat; because my new workman had told me, that the stronger the corn was, the better and more regularly the mowing would be performed. My neighbouring husbandmen, and all the reapers employed by them, thought me out of

my senses; and some of them even came to reason the matter with me. They meant well, and I took it kindly; but desired them carefully to notice the event.

"My experiment was made upon three pieces of wheat, of ten acres each, situated in much more extensive fields of the same corn; so that there was the fairest room to make a just comparison between the operation of the scythe and that of the sickle.

"Some of the neighbouring husbandmen had the curiosity to see the work performed, and were surprised to find that less corn was shed in this way, than in the common practice of reaping with the sickle. They thought the method good; but made a few objections to some particular circumstances, in which the experience of subsequent years shewed them that they were wrong. Their entire approbation then followed; and their mowers, finding that they should be able by this means to cut down all their corn without the assistance of strolling strangers who often do their work very badly, gladly learnt the new method, and commended it to others.

"This trial succeeded so well, that I resolved to cut all my crops in the same manner; and that nothing might be wanting to perfect my mowers in this practice, I procured a sufficient number of expert workmen, masters of the art, from the village of Trie, near Valenciennes, to assist and instruct them for the harvest of 1753.

"This work required a precaution which has been duly attended to ever since: it is, to pick all the stones from off the land, every year, as carefully as possible. The expence of so doing is a very trifle, when compared to the advantages attending it. All the roads around my land, which were formerly impassible in winter, are now firm and good, fit for any carriage. We no longer hear of horses lamed, or waggons overturned by them; and, which is equally true, I find that my ground now requires a less quantity of seed.

"I have now practised this method, in an extensive manner, during five successive years, in the course of which, I have had opportunities of experiencing every circumstance necessary to be considered in order to determine its real merit; I mean, mowing in rainy weather, and cutting of corn either bent, laid flat, totally lodged or lodged only in particular places, and in various directions. I shall first describe the mechanism of this mowing, and then point out its advantages, with the objections of my neighbours, which will shew the only inconveniencies I have met with.

"The Flemish mowers whom I employed in the year 1753, brought with them scythes exactly like ours. I saw no sort of difference in their size, make, manner of being mounted, or even in the hooks they were trimmed with; so that I found I had been misinformed by those who told me in 1751, that this work required an instrument different from that which is used for mowing oats. It was not till the year 1755, that an ingenious workman pointed out some very proper alterations, which have since been made.

"This intelligent mower observed that the common scythe cannot suit any ground but such as has been plowed flat; that it therefore was least of all proper for our lands, which are plowed in ridges of ten or twelve furrows, raised very high in the middle; and that its hooks broke the straw, plucked off numbers of ears, and did not lay hold of many short plants which grow in the bottom of the furrows, whereby a loss was occasioned, or take up the intermixed grass and weeds so exactly as might be wished. To remedy this, he took a scythe at least six inches shorter than those which are commonly used, and, instead of the hooks, substituted what he calls the bender, consisting of two shoots of willow, or other green wood, placed semicircularly upon the handle of the scythe, where the hooks are commonly set. To this end, there must be four holes in the handle, so that the end of one twig may be put into the lowermost hole, and its other end into the third, and the two ends of the other twig into the second and fourth holes. The scythe thus trimmed is to be used in the manner I shall now explain.

"When a mower sets about cutting down a crop of oats, he places himself so that the corn is at his right-hand, from whence the action of the scythe throws the

waving towards his left. The mower of wheat, on the contrary, proceeds from outside to inside, so that the corn which he is next to cut is always at his left hand; and that which he has just cut, being collected by the bender, is rested, inclining a little, against the adjoining uncut part.

"A helper, which may be a boy of twelve or fifteen years of age, or an elderly woman, follows the mower at the distance of four or five feet; with a reaping hook, or a stick about a foot and a half or two feet long, and, by putting that through the interval between the sloping late cut wheat, and the standing corn against which it rests, takes up the former, gives the straw ends a gentle stroke or two upon the ground, to form that parcel into a grip, and lays it down at his right hand. This should be done very expeditiously, because the picker-up, as this person is called, is followed by another mower; and it should also be done dexterously, because the greater or less quantity of gleanings depend thereon. There should be as many pickers-up (we call them binders), as there are mowers.

"The posture of the mower is a circumstance of such importance, that I think myself happy in having taken particular notice of it in 1754. In cutting grass and oats, the mower goes in such manner that his feet, which are moved alternately at each stroke of the scythe, describe two parallel lines. But in the mowing of wheat, the mower's track should be upon a single line, so that his right foot, which should be foremost, be driven forward by the left, at each cut of the scythe; not unlike the attitude of a fencer when he advances.

"An accident, which had like to have over-set my whole operation in the year 1754, demonstrated to me the necessity of this different posture. I employed for mowing my wheat, men who used to come yearly to cut down my oats: they were seven in number. On the third day of their labour, five of them fell ill; upon which I set three others to work; but the consequence was, that I had ten sick people to take care of at the end of the week. I visited them, inquired into their ailments, and found, that some of them had a fever, but that all complained of violent pains and soreness under their left ribs. At first, I inclined to think them pleuritic; but upon a closer examination, and upon considering the nature of the work they had been at, I saw their illness had proceeded from badly managed hard labour, the stress of which had been made to lie chiefly upon the left side. I therefore ordered them to take their rest.

"The next day upon visiting my infirmary, I found that two of the mowers were returned to their work. I went out to them, and saw, even at some distance, that their posture in this work was the same as if they had been mowing of oats. This immediately shewed me the cause of their pains. The scythes which they then used had the common sort of hooks, and were much heavier than those with only wicker benders. I took up one of them, put myself in the posture of a mower of oats, and shewed them, that as a much greater weight rested upon the hooks of the scythe when they mowed wheat, than when they cut oats; it was not possible for them, in the posture they had chosen, to move that increased load to the left, without an irksome twisting of the body. Then, putting myself in the posture of a fencer, as I had seen my Flemish mowers do the year before, I demonstrated to them, that the body was thereby placed in such an attitude as enabled it to exert the greatest strength, when, by the motion from right to left, it had the greatest load to support, and that, by the same means, this load was carried round without fatiguing the ribs of either side. My man took back his scythe, tried as I had directed, was convinced of the truth of my demonstration, taught his companions the same method, and they have done their business easily ever since. I thought it necessary to relate the circumstances of this accident, because I am satisfied that even the strongest men would sink under the labour of mowing wheat, if they were to stand in the same posture as the mowers of oats.

"Such is the manner in which this operation should be performed, when the corn stands upright, that is to say, in the most favourable years. I ought to add, that the mower should take care to place himself for his work,

in such manner, that his left hand may be toward the wind. The corn is then naturally inclined over the scythe, and is the more easily cut closer to the ground. The resistance of the wind, be it ever so little, helps to keep the corn which is cut steady upon the benders of the scythe, and facilitates the motion which rests it against the uncut corn, where the binder takes it.

"The mower is not hindered from mowing close, by the wind's blowing at his back; but the corn which he cuts will not be so exactly collected by the binder: some of the ears will be a little scattered: but the greatest inconvenience is, that it does not rest so well against the standing corn, but is often blown down; which renders the binder's work slower, and more troublesome, and occasions greater gleanings.

"The wind is in a bad corner for the mower when it blows in his face. It then occasions a loss of stubble, and a great dispersion of the ears.

"But the worst of all winds for this work, is that which blows upon the right hand of the mower. The stubble then remains long, and so great a quantity of ears lies scattered about, that one would hardly think the ground had been harvested. My mowers did not place themselves in this manner of their own accord; but I made them do it for a quarter of an hour, to try the effect, of which I am fully convinced.

"When the corn is inclined, or bent, the mower takes it in the direction of its bending, from left to right; which has the same effect, in calm weather, as if the wind blew towards his left.

"Corn which is lodged cannot easily be mowed inward, because the binder would be incessantly impeded by the intangling of his grip with the un-cut corn. A good mower judges by his eye, which part it is most proper to begin at, and takes advantage of the wind when it can be of service to him. The method which I have seen most commonly practised, has been by taking the corn in the direction of its bending, and throwing it in waves. The work thus done is neatly performed: no remains of stubble are seen after the mowing; but the field looks like a meadow.

"Corn laid absolutely flat, and intangled, is the most difficult to cut well. I have seen a mower take it in every various direction in which it was beaten down, as if the wind had been constantly at his back, and by this means he has cut as close as if it had been only lodged. My wheat was in this condition in the year 1757, and was mowed very regularly: only the work was somewhat longer about, than it generally is in other cases.

"I shall not speak of rainy seasons till I come to the objections against this method of cutting corn; because they have nothing to do with our mowing, and the only thing requisite in such cases is to keep the corn from sprouting in the ear: but I shall here relate the advantages which I find in this practice.

"The preservation of my fellow creatures is so dear to me, that I look upon the means of lessening their excessive hard labour at a time when the heat alone is enough to over-power them, as the first and greatest advantage resulting from this method. Now I see that a good reaper, with his sickle, can scarcely cut an acre of wheat in a day, let him toil ever so much; whilst the mower will dispatch from an acre and a half to upwards of two acres, according to his skill and dexterity. I have, indeed, met with but few able to exceed two acres; when they have done their business well; but we may reckon that a good mower, taking them one with another, and the corn as it runs upright, lodged, intangled, &c. will clear an acre and a half, or perhaps an acre and three quarters in a day, neatly, and without wasting any of it.

This mower does then three fifths more work than a reaper can. It is true, he has not the grips to tie up, because the person who follows him does that part: but he is obliged to whet his scythe when he comes to the end of the field, and still oftener when the corn does not grow thick; besides which, notwithstanding all the care that can be taken to clear the ground of stones, not a day will pass without his meeting some, which will oblige him to have his scythe new hammered; and lastly, when he has finished a row, he must go back to the other end of the

field before he can begin another. All this takes up at least as much time as the reaper's binding up what he has cut: and in regard to the hardness of the labour on each side, I believe that every one who rightly considers the nature of their respective works, and their postures in working, will allow, that the mower's toil and fatigue is three-fifths less than that of the reaper.

"Another circumstance well worth attending to, in this method, is, that the mower is not exposed to those injuries from thistles, thorns, and other noxious plants, which often prove fatal to the reaper.

"From the first of these advantages result several benefits: 1. A greater riddance of the necessary work. Not a year passes without the husbandman's experiencing that some part or other of his corn ripens too suddenly; and this unexpected maturity, being exceedingly heightened by the least delay, occasions a great waste, by the shedding of the grain, both when the crop is reaped with the sickle, and in loading and un-loading it when carried home: whereas the scythe, by clearing in two days a field which could not be reaped in less than five, in the common way, guards against that excessive ripeness.

"2. This method of cutting down the corn requires fewer workmen.—I must here explain myself; because the fact would contradict me, if it be objected that a mower and a binder are necessary in this way, for what the reaper alone does in the other. But I consider, that to harvest ninety acres, for example, of wheat, I must employ ten men at least twenty days, with the sickle; whilst seven mowers and their binders (fourteen people) easily do my business in ten days. The difference then is equal to sixty days work of one man; and if I do not intend to get my harvest in quicker with the scythe than with the sickle, I take but four mowers and four binders, eight persons, of which the four last stand me in less expence than three reapers; because I employ for this business young people, who would not be strong enough to reap with the sickle. Consequently I have two workmen the less, and some advantage in the comparison between the grown-up man, who has a higher price, and the lad, who answers my purpose.

"3. The thus employing of children, old women, and men whose constitution is not robust, would be an advantage to the inhabitants of the place. It would afford the means of subsistence to a greater number of people, and prevent idleness and beggary; an important object upon many accounts. Almost every parish would find within itself hands enough to get in its harvest, without being obliged to have recourse to accidental passengers, who often work badly, require exorbitant wages, and sometimes leave their masters in the middle of the harvest, if they do not submit to their unconscionable demands.

"Let us leave speculation, and notice some advantages which are evident beyond contradiction. 1. It is not a small one to have a greater quantity of straw, and that straw intermixed with more grass and other fodder, than when the corn is reaped in the usual way. This does not need any proof; for every one knows, that the scythe cuts as close to the ground as the mower pleases. Experience has shewn me, that the stubble has not been left two inches long upon our mowed fields, where the stones had been carefully picked off; whilst the sickle generally leaves it eight or nine inches long, and sometimes much more when the ground is infested with thistles and other stubborn growths, which make the reaper lift up his hand to avoid them. The straw is therefore plainly six inches longer when cut with the scythe, than with the sickle; a difference which may be valued at a sixth part more than that which is usually reaped in the common way.

"2. The green fodder in the mowed fields shoots up anew when cut, and affords excellent pasture after the corn is taken off. The same demonstrative evidence as before, will again take place here with those who but consider, that the reaper, leaving the stubble either eight or nine inches long, takes off only the very tips of the grass which chances to be within his grip; so that, being then near its time of maturity, it ripens its seeds, sows them, and withers away: whereas, when the scythe

cuts it within two inches of the ground, in its greenest and most un-ripe part, the yet remaining eyes, and the crowns of the roots, send forth new shoots, which form a good after-crop for cattle.

"3. The pasture upon fields mowed with the scythe, is attended with an advantage, in regard to cows, which may perhaps be peculiar to my country. I know not whether it be the same elsewhere. We find every year, and I have always taken particular notice of it, that our cows cease to yield milk during the first week of their feeding among the wheat stubble. I take the reason of this to be, that the stubble gets into their nostrils, pricks them, hinders them from feeding, and makes them range the whole field over in quest of grass unattended with this irksome inconvenience; so that they spend their time in running about, without grazing. I do not find that this accident happens to cows which are turned in among the short stubble left by the scythe: the grass there soon shoots up a-new, and yields me plenty of pasture, especially if a little rain happens to fall after harvest.

"It results from hence, that the husbandman is enabled to feed more cattle than he could otherwise do, to save his sainfoin or lucerne, and to have a greater quantity of dung; as I have experienced with almost incredible success.

"I now proceed to the objections, which I shall state in the same order as they were made; that is to say, as each year gave room for one or other of them.

"The first was, that the scythe must make the corn shed very much by shaking it considerably. To affirm the contrary may seem paradoxical; though the assertion will be proved from manifest principles, and by facts. To judge rightly of my proposition, it will be necessary to compare the operation of the scythe with that of the sickle; both of which I have examined very attentively.

"The reaper presents his hand to the corn, and with wide extended fingers grasps as much as he possibly can; after which, to bring the lower part of the stalks so close together that the sickle may encompass the whole of his grip, and at the same time to give it a tension which renders the action of the sickle more certain, he gives it a violent shake, and at that instant cuts it. The grip thus cut is generally entangled with the standing corn; or the reaper, when going to lay it down, finds that he has missed cutting a stalk, or perhaps more, which he then breaks with a jerk of his hand. Thus several shakes precede that which the corn receives afterward when it is tied up.

"The scythe has not these effects. I have already explained the mechanism of its operation, and shewn that the corn, cut without any violent shake, is carried gently by the bender (or cradle, as we more commonly call it) upon the scythe, to the standing corn, against which it rests inclined, till the binder takes it away to tie it up.

"To prove my proposition by facts, I instance the following. After my wheat was mowed in the year 1752, in the manner before related, upon the three several spots of ten acres each, which were parts of much larger fields, I went, with four other persons, purposely to examine with all the care we could, what quantity of grain might have been shed by the mowing. We found none at all in the two first mowed pieces; but a great deal in the other parts of the same fields which had been reaped with the sickle. In the last piece, which was not cut till the corn was ripe, we found a little grain in the mowed part, but incomparably more in the other. I did not repeat this search every year with the same care, because I had not always the same conveniences of making a comparison: but I have seen enough to be certain that no grain is shed unless the corn be exceeding ripe, and that much less is then lost by the scythe, than by the sickle.

"The following more important objection was afterward made by a sensible husbandman, who observed to me, that, in a rainy year, the corn cut after this manner must be more liable to grow in the ear, than that which is reaped in the common way, because the heads of the grips not being supported here by a pretty high stubble,

the wet cannot well drain off; and that the grain will imbibe a great deal of moisture from the grass underneath, when the ear is beaten down upon it by rain, which will render it very apt to sprout as soon as the sun shines upon it. I had been told how to guard against this accident, but did not try the method till the year 1756, when it answered perfectly well.

"This method consists in laying the grips in a triangular form, so that the head of one rests upon the foot of another. This operation is neither long nor fatiguing; nor does it require, in order to do it quick, any thing more than a little dexterity in closing the triangle, by making the foot of the third grip support the ears of the first. The rains which fell during the harvest of 1756, rendering the getting in of that year's crops extremely troublesome, my neighbours had a great deal of sprouted corn; but mine escaped by this method; and what little I had proceeded from that which remained un-mowed when the rain became incessant.

"With regard to the sheaves, when bound, my Flemish mowers informed me, in 1753, of their practice when they are overtaken by lasting rains. It is, to heap upon one another, ends to ends, as many sheaves as they can possibly cover with one, which is then opened and laid over them. My people did not practise this method, which I believe the best; but they secured my corn by other means, which answer extremely well, and are generally known.

"From the above objection my husbandman derived another, relative to the difficulty of drying the grass and weeds intermixed with the corn, in rainy years, and the danger of housing the sheaves when full of that trash, which may ferment, and be the occasion of the rotting of a whole pile of wheat. I cannot answer this objection otherwise than by my experience. The harvests of 1756 and 1757 were certainly not favoured by the weather: yet all the wild growths which were cut down with, and bound up among the sheaves, were well withered when they were housed. No sort of smell which indicated the least fermentation was perceived in any of my barns; the threshers did not find any thing that looked like it; and the straw which is taken from those barns, to feed my horses, attests that there was not any.

"I now come to the last objection; by so much the more serious, as it is one of those inconveniences which I cannot remedy, but to which I readily submit. The ears of the corn, say the objectors, do not lie so even in your grips, as in those which are reaped with the sickle; some of them are in the middle, and others at the very bottom of the sheaf; so that your corn is not threshed so well or so regularly, and you thereby lose perhaps a considerable part of it. 2. All the grass and weeds contained in your sheaves are threshed with the wheat, and their seeds are mingled with the corn when the thresher measures it out; consequently you pay him for threshing this trash, which again increases the labour and pay of the winnowers.

"All this is true: but let us discuss the matter a little more thoroughly. There are ears in the middle and at the bottom of my sheaves; but they seldom are of any other kind than those which we call backward or late ears; the weak productions of sickly plants, or of seeds not perfectly sound. Repeated examinations have convinced me, that very few others are in this case; and these ears hardly part with their grain at any time, in whatever manner they are threshed; for though the grains be torn from off them by the action of the flail, the inmost husk still adheres to the corn. These diminutive imperfect grains are so great a detriment to the fine, plump, well nourished corn, that they lessen its value, if not carefully separated by winnowing; after which they serve to feed poultry. If these ears escape the flail, the straw is so much the better. Our horses and other cattle reap therefrom a benefit which we ought not to grudge, because, I think, it turns to our advantage.

"The threshed grass, and other wild productions, do indeed yield a considerable quantity of what are commonly called bad or useless seeds, for the beating out of which I pay the thresher. But the grass which occasions this expence, saves me that of a great deal of sainfoin

foin and lucern, which my cattle would consume: and it would be unjust in me to complain of the additional charge in the winnowing, since my manager has thought of applying those seeds to domestic purposes, such as feeding fowls, &c. which prove more profitable to me than an equal quantity of the finest corn.

"A real increase of expence, is what I pay the thresher beyond the common price of the country. This difference, which consists in two-pence or three-pence for a quarter of wheat, is but a just compensation for his extraordinary trouble in unbinding and binding up again perhaps an hundred and fifty sheaves, and sometimes more, for what an hundred sheaves generally yield, when reaped in the common way. But this expence is so amply repaid by the extraordinary quantity of straw obtained by my method, that I rate the difference at more than the value of five quarters of corn, which to silence contradiction, I will suppose to be otherwise lost in my practice. Still my crop is cut down and housed with far less toil and expence, than if it was reaped."

We shall conclude this article with the following comparative calculation of expence and profit between the drill and the common husbandry, taken from Mr. Barker's report to the Dublin Society of his experiments in agriculture, for the year 1765, published by order of the Society.

An Estimate of the Expence upon a Plantation Acre of Wheat, in the common Husbandry.

	l.	s.	d.
To the first plowing, commonly called breaking, for fallow, eight horses eight shillings; two plowmen one shilling and four-pence; two drivers one shilling	0	10	4
To the first harrowing, four horses four shillings; a driver six-pence	0	4	6
To the second plowing, commonly called gaurowing	0	10	4
To the second harrowing	0	4	6
To the third plowing, commonly called stretching	0	10	4
To sowing the seed, eight horses eight shillings; two plow-men one shilling and four-pence; two drivers one shilling; the seed-man eight-pence	0	11	0
To seed wheat, one barrel	1	0	0
To rent for the year of fallow	0	18	0
To ditto, the year the crop is growing	0	18	0
	5	7	0

In this account forty shillings are charged for forty horses, employed in the culture of one acre for wheat, in the common husbandry; a charge which ought to be considered by the farmer, for he actually buys and maintains his horses for this business.

The crop which follows wheat is generally oats; but sometimes peas are sown instead of oats; with some, the practice is to let the peas follow oats; in which case they fallow only every fourth year; but where land receives no other assistance than what arises from fallow, it is a bad practice not to fallow every third year. It is the general practice to plow but once for oats, and therefore it shall be stated so; but it is a much better practice to plow the wheat stubble once before winter, and again in the spring.

An Estimate of Expence upon an Acre of Oats.

	l.	s.	d.
To plowing once	0	10	4
To seed oats, 2 barrels	0	12	0
To harrowing, 4 s. 6 d. seed-man 4 d.	0	4	10
To one year's rent	0	18	0
	2	5	2

These two crops consume three years; after which the farmer is to begin again, and to incur every article of expence stated in the above accounts, in order to obtain two crops more.

An Estimate of Expence upon a Plantation Acre of Wheat in the Drill Husbandry, the first Year.

	l.	s.	d.
To plowing 4 times, to prepare the fallow	2	1	4
[This is the same charge as in preparing for the common husbandry.]			
To harrowing twice for ditto	0	9	0
[This is the same also.]			
To rent for the year of fallow	0	18	0
[This charge is saved after the first year.]			
To harrowing with the drill harrows	0	0	6 ½
[Four acres a day may be harrowed with one horse.]			
To sowing with the drill plow	0	1	1
[From 3 to 5 acres may be sown in a day.]			
To seed-wheat, generally 5 stone, but suppose 6	0	6	0
To the first, or winter hoeing	0	1	7
[Two acres may be hoed in a day, two horses, plow-man and driver: the design of this hoeing is to leave the plants dry, and to meliorate the earth.]			
To the spring hoeing with the cultivator	0	1	1
[To deepen the soil, one horse, plow-man and driver.]			
To the 3d hoeing, i. e. to return the meliorated earth to the corn	0	1	7
[To make the corn tiller, i. e. to increase its branches.]			
To the fourth and final hoeing	0	1	1
[To fill the grain and render it large.]			
To rent, the year the corn is growing	0	18	0
	4	19	3 ½

N. B. Although the drill culture for the first year is very near as expensive as the common, yet, after taking the first crop, the expence and labour of fallow, and loss of time, is not to be incurred again, as is unavoidable in the common husbandry.

An Estimate of Expence upon an Acre of drilled Wheat, after the first Crop.

	l.	s.	d.
To plowing the land once	0	10	4
[One plowing is all that is necessary.]			
To harrowing with the drill harrow	0	0	6 ½
To sowing with the drill plow	0	1	1
To seed-wheat	0	6	0
[Be it remembered, 5 stone is enough.]			
	0	17	11 ½
To four times horse-hoeing, as before stated	0	5	4
To one year's rent	0	18	0
	2	1	3 ½

Thus the land is sown again with wheat every year, and instead of 4 l. 9 s. which is the farmer's expence in the common husbandry, exclusive of one year's rent of the land; in the drill method it is no more than 17 s. 11 ½ d. and the total expence, instead of 5 l. 7 s. is no more than 2 l. 1 s. 3 ½ d. rent included; whereby there is a saving of 3 l. 5 s. 8 ½ d. an acre.

Before the account of profit and loss upon these different methods of culture be stated, it will be necessary to take notice of an objection, which may perhaps be made to the above charge of plowing in the common husbandry. It is pretended, that three quarters of an acre may be plowed in a day, with one plow: but can it be done effectually? The land may, indeed, be scratched, but cannot really be plowed as it ought to be. The farmer ought to be cautioned against a trick too frequently practised in plowing. When a plow-man enters his plow, and passes across the field, he turns a sod about a foot broad; when he is to return, he enters his plow about four feet distant from the out-side of the former furrow, and so turns another sod of the same breadth, which, when turned, just meets the former sod;

fod; thus four feet of the land appear to be plowed, whereas the fact is, that the two feet lying under the fods is not touched with the plow at all. This deception, added to the practice of just skimming the ground, enables hirelings to undertake plowing at 6 and 7s. an acre. But if a plantation acre of land be well and effectually plowed, 10s. 4d. as charged above, will not appear too much; and it is, in fact, supported by the common course of business.

When wheat is to be sown, it is the general custom to send a barrel of seed into the field with two plows, which is to sow an acre of land, and that is the usual day's work for two plows in the general course of business. Let us see then what the expence will amount to. Eight cattle will be 8s. two plow-men 1s. 4d. two drivers 1s. and the seeds-man 8d. which in all makes 11s. and corresponds with the above charge.

To clear profit arising upon an acre of land in fifteen years in the drill husbandry	52	3	11
To clear profit arising upon an acre of land in fifteen years in the common husbandry	27	19	2
Greater profit on the drilled acre, in fifteen years	24	4	9

Which amounts to 11. 12s. 3½d. per annum, for fifteen years on the acre, more than by the common husbandry.

In the drill husbandry the crops are stated at three barrels of wheat less upon an acre than in the common husbandry, that it may not be supposed to be over-rated; but in the common husbandry, the crops are rated at the highest; fourteen barrels of oats an acre, are also allowed in the common husbandry, which every farmer must admit to be a great allowance upon the general produce.

Doubtless, it will be observed, that in fifteen years fourteen wheat crops are obtained in the drill husbandry; in the common husbandry only five wheat and five oat crops; the five other years are not only lost, but are an heavy expence to the farmer.

A farmer having forty acres of tillage, supposing him to direct his attention to bringing it to the drill culture, would make in fifteen years 969l. 10s. more than he can in the common husbandry; which is such an advantage, that the greater profit in the drilled acre in fifteen years will purchase the fee-simple of that in the

common husbandry, at twenty seven years purchase, valuing the land at 18s. an acre.

Thus it appears, that in every fifteen years the fee-simple of all the tillage land of the kingdom, is lost to the community by the common course of tillage.

In stating these accounts, no mention is made of fences, water, cutting the land, weeding and reaping, as these articles of expence depend on a variety of circumstances, but, in general, will be more on the common husbandry than on the drill.

WHEEL, *Rota*, in mechanics, a simple machine, consisting of a round piece of wood, metal, &c. which revolves on an axis.

WHEEL-*Carriages*. The whole doctrine of wheel-carriages (as it is founded on a mathematical theory) may be reduced to the following particulars, viz. (1.) wheel-carriages meet with less resistance than any other. (2.) The larger the wheels, the easier the draught of the carriage. (3.) A carriage upon four large wheels, of equal size, is drawn with less force than with two of those wheels and two of a lesser size. (4.) If the load be laid on the axle of the larger wheels, it will be drawn with less force than if laid on the axis of the lesser wheels, contrary to the common notion of loading carriages before. (5.) The carriage goes with much less force on friction-wheels, than in the common way.

WHEEL is also the name of a kind of punishment which great criminals are put to in divers countries. In France, their assassins, parricides, and robbers on the highway, are condemned to the wheel; i. e. to have their bones

first broken with an iron bar on a scaffold, and thus to be exposed and left to expire on the circumference of a wheel. In Germany they break their bones on the wheel itself.

WHEEL, in the military art, is the word of command, when a battalion or squadron is to alter its front either one way or the other. To wheel to the right, directs the man in the right angle to turn very slowly, and every one to wheel from the left to the right, regarding him as their center; and *vice versa*, when they are to wheel to the left. When a division of men are on the march, if the word be to wheel to the right or to the left, then the right or left hand man keeps his ground; only turning on his heel, and the rest of the rank move about quick till they make an even line with the said right or left hand man.

WHEEL-ANIMALS, *Brachionus*, a genus of animalcules which have an apparatus of arms for taking their prey. This apparatus has been supposed by microscopical writers, to be a kind of wheels, and thence named the creatures that are possessed of it wheel-animals.

This is one of the smaller animalcules; and is, by Dr. Hill, described to be, when in a state of rest, of a plane smooth body, of a conic figure, obtuse at the posterior extremity, and open at the anterior, of a dusky olive colour, and semi-transparent. When it puts itself in motion, it protrudes, from the open extremity, a part of its naked body; to the whole of which this outer-conic body seems to be but a case or sheath; from the extremity of this exerted part of the body, the creature soon after thrusts out two protuberances, which give it the appearance of a double head; and in each of these is discovered an apparatus in a continual motion, appearing a rotatory one, but in reality a vibratory one very quick repeated. Each of these protruded bodies has six arms inserted into it, and these it continually shuts and opens over one another. Each of these arms is furnished with double series of fibres at its edge, which being expanded cause it to spread to a considerable breadth. There are several species of this genus of animalcules.

WHEEZING, a name given by our farriers to a distemper in horses, in which they draw their breath with difficulty and noise.

The generality of people make this and purfiness in horses the same distemper; but the more judicious always distinguish it, as wholly different from that. Purfiness proceeds always from a stuffing or oppression of the lungs; but this wheezing is only owing to the narrowness of the passages between the bones and gristles of the nose.

The horses that are most of all afflicted with this distemper, do not want wind; for notwithstanding they wheeze excessively when they are exercised, yet all the time their flanks are not moved, but keep in the same condition that they were while the creature stood still. The dealers call these sort of horses blowers, and though there is no real harm in the thing, it is a disagreeable quality, and few people will chuse them that have much service for them.

There are some horses that have a natural defect in their breathing, which makes it at all times attended with some difficulty, but not with the wheezing before-mentioned; these are called thick-winded horses.

People who are careful in the buying horses, will purchase neither of these kinds; but then is this caution to be observed in regard to this defect, that it often seems to be in horses where it really is not. When a horse has been kept a long time in the stable without exercise, he will, at the first riding, be out of breath, and fetch it in a difficult and painful manner, though he be neither a blower or thick-winded; but all this will go off with a little exercise.

There are some temporary wheezers and blowers among horses: these, at times, rattle, and make a great noise through their noses in taking breath; but the complaint goes off and returns. This is only occasioned by a great quantity of phlegm, for their flanks do not redouble with it at the worst of times, nor have they any cough with it; so that there is no danger of their being purisy.

WHELP, the young of a dog, fox, lion, or any wild beast. Nothing is more essential to the having a good pack of hounds, than a proper care of the whelps, and of the parents from which they are to be bred. The bitches in particular should be carefully chosen, and should be such as are strong and well proportioned; they must also have large ribs and flanks.

The whelps must have good fresh straw to lie in, and it must be often changed; they are to be kept in a place where neither the rain nor sunshine can be troublesome to them, and once a week it will be proper to anoint them all over with a little nut-oil, with some saffron infused in it. This will prevent the flies from annoying them so much as they otherwise would, and will kill worms of all kinds. When they are fifteen days old it is the custom to worm them, and a week after, one joint of their stern should be twisted off. As soon as they can see, they should have milk given them to lap; and at two months old, they should be weaned, keeping them wholly from the bitch. They must at this time be well kept, but not too high fed; and it is proper to put some cummin seed into their food, to keep the wind out of their bellies.

WHELPS, in a ship, the seaman's term for those brackets which are set up on the capitan close under the bars; they give the sweep to it, and are so contrived, that the cable winding about them may not surge so much as it might otherwise do, if the body of the capitan were quite round and smooth.

WHETSTONE, *Cos*, a stone which serves for the whetting of knives and other tools upon.

WHEY, the serum, or watery part of milk.

WHIFFLER of a company, in London, a young freeman who goes before, and waits on the company on solemn assemblies.

WHIG, a party in England opposite to the tories, from whom they differ chiefly in their political principles. See **TORIES**.

The names of whig and tory were not known till about the middle of the reign of Charles II. when these were given as party distinctions. These parties may be considered either with regard to the state, or to religion. The state tories are either violent or moderate: the first would have the king to be absolute, and therefore plead for passive obedience, non-resistance, and the hereditary right of the house of Stuart. The moderate tories would not suffer the king to lose any of his prerogative; but then they would not sacrifice those of the people. The state whigs are either strong republicans or moderate ones. The first, says Rapin, are the remains of the party of the long parliament, who attempted to change the monarchy to a commonwealth: but these make so slender a figure, that they only serve to strengthen the party of the other whigs. The tories would persuade the world, that all the whigs are of this kind; as the whigs would make us believe that all the tories are violent. The moderate state whigs are much in the same sentiments with the moderate tories, and desire that the government may be maintained on the ancient foundation: all the difference is, that the first bear a little more to the parliament and people, and the latter to that of the king. In short, the old whigs were always jealous of the incroachments of the royal prerogative, and watchful over the preservation of the liberties and properties of the people.

In regard to religion, the whigs have always been for limiting the power of the bishops, and abolishing the convocation.

WHIP, or **WHIP-STAFF**, in a ship, a piece of timber, in form of a strong staff, fastened into the helm, for the steersman, in small ships, to hold in his hand, in order to move the rudder and direct the ship.

WHIRL-POOL, an eddy, vortex, or gulph, where the water is continually turning round. In rivers these are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous.

Sibbald has related the effects of a very remarkable marine whirl-pool among the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is

not fixed to any particular place, but appears in various parts of the limits of the sea among those islands. Wherever it appears it is very furious; and boats, &c. would inevitably be drawn in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw or some such thing, in the boat with them: as soon as they perceive the whirl-pool, they toss this within its vortex, keeping themselves out. This substance, whatever it be, is immediately received into the center and carried under water; and as soon as this is done, the surface of the place where the whirl-pool was becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distant from the first. See the articles EDDY and VORTEX.

WHIRL-WIND, a wind that rises suddenly, exceeding rapid and impetuous, when risen, but soon spent.

There are divers sorts of whirl-winds, distinguished by their peculiar names; as the prester, typho, turbo, exhydria, and ecnephas.

The prester is a violent wind, breaking forth with flashes of lightning. This is rarely observed; scarce ever without the ecnephas. Seneca says, it is a typho or turbo kindled or ignited in the air.

The ecnephas is a sudden and impetuous wind, breaking out of some cloud, frequent in the Ethiopic sea, particularly about the Cape of Good-Hope. The seamen call them travados.

The exhydria is a wind bursting out of a cloud with a great quantity of water. This only seems to differ in degree from the ecnephas, which is frequently attended with showers.

A typho, or vortex, most properly called whirl-wind, or hurricane, is an impetuous wind, turning rapidly every way, and sweeping all round the place. It usually descends from on high. It is frequent in the Eastern-ocean, chiefly about Siam, China, &c. and renders the navigation of those parts exceeding dangerous.

WHISPERING PLACES depend upon this principle: if the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means prevented from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it otherwise would be.

Hence it is, that sound is conveyed from one side of a whispering-gallery to the opposite one, without being perceived by those who stand in the middle.

The form of a whispering-gallery is that of a segment of a sphere, or the like arched figure; and the progress of a sound through it may be illustrated in the following manner:

Let ABC (plate CXL. fig. 3.) represent the segment of a sphere; and suppose a low voice uttered at D, the vibrations expanding themselves every way, some will impinge upon the points E, E, &c. and from thence be reflected to the point F, from thence to G, and so on till they all meet in C, and by their union there, cause a much stronger sound than in any part of the segment whatever, even at D, the point from whence they came. Accordingly, all the contrivance in whispering places is, that near the person that whispers there may be a smooth wall, arched either cylindrically or elliptically. A circular arch will do, but not so well.

The most considerable whispering places in England are, the whispering-gallery in the dome of St. Paul's, London, where the ticking of a watch may be heard from side to side, and a very easy whisper be sent all round the dome. The famous whispering place in Gloucester cathedral, is no other than a gallery above the east end of the choir, leading from one side thereof to the other. It consists of five angles and six sides, the middlemost of which is a naked window, yet two whisperers hear each other at the distance of twenty-five yards.

WHITE, one of the colours of natural bodies. See COLOUR.

White is not so properly said to be any one colour, as a composition of all colours; for it is demonstrated

by Sir Isaac Newton, that those bodies only appear white, which reflect all the kinds of coloured rays alike.

WHITE, in painting in miniature, &c. The best white for painting in water-colours, is flake white, which is better than white lead; and if it be pure, far exceeds it in beauty; because white lead is apt to turn blackish, especially if it be used in a hard water: but if you use white lead, first rectify it with white wine vinegar in the following manner: grind well the finest white lead upon a porphyry with vinegar; then put it into a glass of water, stir it about, and presently pour off the water, while it is white, into some other clean glass or vessel; let it settle, and then pour off the water from it, and it will be exceeding fine. When this white is settled, put to it gum-water, to bind it and give it a glaze.

Some recommend a white made of the whiter part of oyster-shells, reduced into an impalpable powder; this is called pearl white, and will mix with any colour. Some also recommend the powder of egg-shells of the brightest colour, and well cleaned and washed, ground with gum-water, to which may be added about a twentieth part of white sugar-candy: the egg-shells should be ground to an impalpable powder. Experience proves, that egg-shell powder is of very great service as a white in water-colours, and both that and the powder of oyster-shells, well rectified and mixed with the white of an egg well beaten, will make an extraordinary mixture in other colours, and will correct them from changing or altering their qualities.

WHITE of the Eye, denotes the first tunic or coat of the eye, called albuginea and conjunctiva, because it serves to bind together, or inclose, the rest. See the article EYE.

WHITE-FRIARS, a name common to several orders of monks, from their being clothed in a white habit.

WHITE-HART Silver, a mulct or tribute paid into the Exchequer, out of certain lands in or near the forest of White-hart in Dorsetshire; imposed by Henry III. upon Thomas de la Linde, for killing a beautiful white hart which that prince had before spared in hunting.

WHITE-HORSE, in ichthyology, the prickly backed raia, with two series of prickles on the tail, and one series over each eye.

This is a singular species, the body is considerably broad in proportion to its length, but it is also thick; the back is somewhat gibbose, but the belly is more flat; the rostrum is oblong and acute, the eyes are prominent, and there is an aperture behind each; the mouth is transverse and large, and furnished with a number of sharp teeth; the apertures of the gills run down from it on each side along the breast; they are small, and there are five of them on each side.

WHITE-LEAD, also called ceruse. See the article CERUSE.

WHITE-LINE, among printers, a void space of the depth or breadth of a line. See the article PRINTING.

WHITE-MEATS, include milk, butter, cheese, white-pots, custards, and other kinds of food made of milk or eggs. Some also add chickens, veal, and fish.

WHITE-POT, milk or cream beat up with the yolks of eggs, mixed with sugar and spice, and baked in an earthen dish, with slices of bread in it.

The cooks furnish us with a variety of dishes under this denomination; as the rice white-pot, Westminster white-pot, Norfolk white-pot, &c.

WHITE-RENT, a rent or duty of 8 d. paid annually by every tinner in the county of Devon, to the duke of Cornwall.

WHITE-SEA, in geography, a bay of the Frozen ocean, in the north of Muscovy, between Russian Lapland and Samoiada.

Spanish-WHITE, a kind of fucus used by ladies to heighten the complexion, and hide its defects.

It is made of tin-glass dissolved in spirit of nitre, and precipitated into a very fine powder by means of salt-water. See TIN.

WHITE-WINE, wine of a bright transparent colour, bordering on white, thus called to distinguish it from the red wines. See WINE.

WHITE-

The generality of white-wines are made from white grapes; though there are some from black ones, only the skins are kept from tinging them.

WHITENESS, *Albugo*, the quality which denominates a body white. See the articles **WHITE** and **COLOUR**.

Sir Isaac Newton shews, that whiteness consists in a mixture of all the colours; and that the light of the sun is only white, because consisting of rays of all colours. See **RAY**.

From the multitude of rings of colours which appear upon compressing two prisms or object-glasses of telescopes together, it is manifest that these do so interfere and mingle with one another at last, as, after eight or nine reflections, to dilute one another wholly, and constitute an even and uniform whiteness; whence, as well as from other experiments, it appears, that whiteness is certainly a mixture of all colours, and that the light which conveys it to the eye, is a mixture of rays endued with all those colours. See **LIGHT**.

The same author shews, that whiteness, if it be most strong and luminous, is to be reckoned of the first order of colours; but if less, as a mixture of the colours of several orders. Of the former sort he reckons white metals, and of the latter, the whiteness of froth, paper, linnen, and most other white substances. And as the white of the first order is the strongest that can be made by plates of transparent substances, so it ought to be stronger in the denser substances of metals than in the rarer ones of air, water, and glass. Gold or copper mixed either by fusion, or amalgamation with a very little mercury, with silver, tin, or regulus of antimony, becomes white, which shews both that the particles of white metals have much more surface, and therefore are smaller than those of gold and copper; and also that they are so opaque, as not to suffer the particles of gold or copper to shine through them. And as that author doubts not but that the colours of gold and copper are of the second and third order, therefore the particles of white metals cannot be much bigger than is requisite to make them reflect the white of the first order.

WHITING, in ichthyology, the English name for the white gadus with no beard, and with three fins on the back, and the under jaw longest.

The head and body of this species is compressed, the back is convex, the anus is at a great distance from the tail, and is, indeed, very near the head; the colour of the whole fish is a silvery white, except that on the back there is an admixture of a blackish tinge; the scales are very small, roundish and white; the nostrils have each a double aperture, and are placed high; the eyes are very large, the iris silvery, and the pupil large and blue; the teeth are very numerous; the pectoral fins have each six rays; the pinnæ ani are two, and have, the first thirty-three, and the second twenty-two rays. This species is frequent in our seas, and much esteemed at our tables.

WHITES, in medicine, the same with fluor albus. See **FLUOR ALBUS**.

WHITLOW, in medicine. See the article **PARONYCHIA**.

WHITSUNDAY, a solemn festival of the christian church, observed on the fiftieth day after Easter, in memory of the descent of the Holy Ghost upon the apostles in the visible appearance of fiery cloven tongues, and of those miraculous powers which were then conferred upon them.

It is called Whitsunday, or White-sunday, because this being one of the stated times for baptism in the ancient church, those who were baptised put on white garments, as types of that spiritual purity they received in baptism. As the descent of the Holy Ghost upon the apostles happened upon the day which the Jews called Pentecost, this festival retained the name of Pentecost among the Christians.

WHOODINGS, or **HOODINGS**, a sea term, used for planks joined and fastened along the ship's side into the stem.

WHORE, a woman who prostitutes herself for hire.

WHORLBAT or **HURLBAT**, a kind of gauntlet, or leathern strap, loaden with plummets; used by the an-

cient Romans in their solemn games and exercises, and by them called *cæstus*.

WIC, a place on the sea-shore, or on the bank of a river: though it properly signifies a town, village, or dwelling-place; and sometimes a machine.

WICKER, a twig of the osier shrub, single or wrought.

WICKET, a small door in the gate of a fortified place, &c. or a hole in a door, through which to view what passes without.

WICKLIFFISTS, or **WICKLIFFITES**, a religious sect, who had their rise in England, and their name from their leader John Wickliff, a professor of divinity in the university of Oxford.

To that immortal author it is we owe the first hint of the great Reformation, effected 200 years after him.

Wickliff maintained, that the substance of the sacramental bread and wine still remained such after consecration. He also opposed the doctrine of purgatory, indulgences, the invocation of saints, and the worship of images.

He made an English version of the Bible; and composed two large volumes, called *Aletheia*; that is, Truth; which was the source whence John Hus first learned most of his doctrines.

The archbishop of Canterbury called a council against Wickliff, and he was condemned therein; but the good reformer set the condemnation at nought. After this, king Richard banished him out of England; but he was afterwards recalled, and died in his own country in the year 1384.

Forty years afterwards, his doctrines, and the adherents thereto, were condemned by the council of Constance; in consequence of which, his bones were dug up, and the council condemned him for forty errors.

WIDOW, a woman who has lost her husband.

In London, a freeman's widow may exercise her husband's trade, as long as she continues such.

Marriage with a widow, in the eye of the canon law, is a kind of bigamy.

WIDOW of the king, was she who after her husband's death, being the king's tenant in capite, could not marry again without the king's consent.

WIFE, a married woman, or one joined with, and under the protection of, an husband.

A wife, in our English law, is termed *feme covert*; and in the judgment of the law is reputed to have no will, as being supposed intirely under, and subject to, that of her husband.

The wife can make no contract without the husband's consent; and if any goods or chattels be given her, they all immediately become her husband's: even necessary apparel is not her's in property.

All her personal chattels, which she held at her marriage, are so much her husband's, that after his death they shall not return to her, but go to the executor or administrator of her husband, except only her paraphernalia.

The wife partakes of the honour and condition of her husband; but none of her dignities come by marriage to her husband; and as the law supposes the husband to have the full power over his wife, he is obliged to answer for all her faults and trespasses. If a wife bring forth a child begot by a former husband or any other, before marriage, but born after marriage with another man; this latter must own the child; and that child shall be his heir at law; and if a wife bring forth a child during her husband's absence, though it be of many years; yet if he lived all the time within the island he must father the child, and the child if first-born, shall inherit. If the wife has a jointure, and during her marriage is made pregnant by her husband, which must appear by the child's being born alive, the husband shall have all his wife's lands for life; but if the wife have no jointure settled before marriage, she may, after her husband's death, challenge the third part of his yearly rents of land, during her life.

WILDERNESS, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made either to intersect each other in angles,

or

or have the appearance of meanders and labyrinths. See GROVE and LABYRINTH.

Wildernesses, says Mr. Miller, should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees in a small spot of ground; and, on the other hand, nothing can be more absurd than to see little paltry squares, or quarters of wilderness-work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near the habitation, nor so as to obstruct any distant prospect of the country; there being nothing so agreeable as an unconfined prospect; but where, from the situation of the place, the sight is confined within the limits of the garden, nothing can so agreeably terminate the prospect, as a beautiful scene of the various kinds of trees judiciously planted; and if it is so contrived, that the termination is planted circularly, with the concave towards the sight, it will have a much better effect, than if it end in straight lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance. It should also be observed, never to plant ever-greens amongst deciduous trees; but always to place the ever-greens in a wilderness in a separate part by themselves, and that chiefly in sight.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others, and these should now and then lead into an open circular piece of grass; in the center of which may be placed either an obelisk, statue, or fountain; and, if in the middle of the wilderness there be contrived a large opening, in the center of which may be erected a dome or banquetting-house, surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings, the trees should rise gradually one above another to the middle of the quarters, where should always be planted the largest growing trees, so that the heads of all the trees may appear to view, while their stems will be hid from the sight. Thus in those parts which are planted with deciduous trees, roses, honey-suckles, spiræa frutex, and other kinds of low-flowering shrubs, may be planted next the walks and openings; and at their feet, near the sides of the walks, may be planted primroses, violets, daffodils, &c. not in a strait line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, althæa frutex, meze-reons, and other flowering shrubs of a middle growth; and these may be backed with many other sorts of trees, rising gradually to the middle of the quarters.

The part planted with ever-greens, may be disposed in the following manner, viz. in the first line next the great walks, may be placed the laurustinus, boxes, spurge-laurel, juniper, savin, and other dwarf ever-greens. Behind these may be placed laurels, hollies, arbutuses, and other ever-greens of a larger growth. Next to these may be planted alaternuses, phyllireas, yews, cypresses, Virginian cedars, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir growth; and in the middle should be planted Scotch pines, pinaster, and other of the larger growing ever-greens, which will afford a most delightful prospect, if the different shades of the greens are curiously inter-mixed.

But beside the grand walks and openings, which should always be laid with turf, and kept well mowed, there should be some smaller serpentine-walks through the middle of the quarters, where persons may retire for privacy; and by the sides of these private walks may also be scattered some wood flowers and plants, which, if artfully planted, will have a very good effect.

In the general design for these wildernesses, there should not be a studied and stiff correspondency between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.

WILL, *Voluntas*, is usually defined a faculty of the mind, whereby it embraces or rejects any thing represented to it, as good or evil, by the judgment.

Others will have it to be the mind itself, considered as embracing or refusing; adding, that as the understanding is nothing else but the soul, considered as perceiving; so the will is nothing else but the soul considered as willing, &c.

Mr. Locke more intelligibly defines the will, a faculty which the soul has of beginning or forbearing, continuing or ending several actions of the mind, and motions of the body, barely by a thought or preference of the mind, ordering, or as it were commanding the doing, or not doing, such and such a particular action. This power the mind has, to order the consideration of any idea, or the forbearing to consider it; or to prefer the motion of any part of the body to its rest, and vice versa, is what we call the will.

The actual exercise of that power, is what we call volition, or willing; and the doing or forbearing any action consequent on such order of the mind, is called voluntary.

Father Malebranche lays it down, that the will is that to the soul, which motion is to the body; and argues, that as the Author of nature is the universal cause of all the motions in matter, so he is of all the inclinations in the mind: and, that as all motions are direct, unless their course be diverted and changed by some foreign cause; so all inclinations are right, and could have no other end, but the enjoyment of truth and goodness, were there not some foreign cause to determine the natural impression to evil ends.

Accordingly, he defines will to be the impression or natural motion which carries us towards good indeterminate, and in the general; and the power the mind has to direct this general impression towards any particular object that pleases it, is what he calls liberty.

Aristotle distinguishes two kinds of acts of the will; viz. βουλευσις, willing volition; and προαιρεσις, election. The first, that employed about the ultimate end; the latter, about the means.

The schoolmen also distinguish the actions of the will into elicit and commanded. Elicit acts are those immediately produced by the will, and really inherent therein, such are willing; and willing-commanded acts are effects produced by other powers; v. gr. the sensitive, intellectual, or locomotive powers, at the command or instigation of the will.—As, to follow, stay fight, fly, &c.

But others will have the former kind properly to belong to the understanding; and only the latter to the will.

The word will is taken in three senses; 1. For the power, or faculty of willing, in which sense it is we have considered it above. 2. For the act, or exercise of this power; as when we say, No man wills his own destruction. 3. For a habit, or a constant disposition and inclination to do any thing. In which sense, justice is defined a constant will, to give every one what belongs to him.

WILL, or *last* WILL, in law, signifies the declaration of a man's mind and intent relating to the disposition of his lands, goods, or other estate, or of what he would have done after his death.

In the common law, there is a distinction made between a will and a testament; as that is called a will, where lands or tenements are given; and when the disposition concerns goods and chattels alone, it is termed a testament. See the article TESTAMENT.

A will, though it has no force till after the testator's decease, does then, without any other grant, or livery, &c. give and transfer estates, and alter the property either of lands or goods, as effectually as any deed or conveyance executed in a person's life-time, and thereby descents may be prevented, estates in fee, tail, for life, or for years, be made, and he that takes lands by devise is in the nature of a purchaser. Formerly a person could not give away by will those lands that he had by descent, though he might such as he enjoyed by way of purchase; but by 34 and 35 of Hen. VIII. c. 5. all persons that have a sole estate in fee simple of any lands, tenements, &c.

&c. may devise the same by will at their pleasure, to whom they think fit; and this extends to persons seized in coparcenary, or as tenants in common; but lands intailed are not devisable, only those held in fee, and goods and chattels: but wills made by infants or feme covert, idiots, and persons not of sound memory, are deemed not good in law. The 29 Car. II. c. 23. has enacted, that all wills and devises of lands, &c. shall be in writing, signed by the devisor, or some other by his express directions, in the presence of at least three credible witnesses; and no will made in writing shall be revoked, but by another will, or cancelling the same by the testator himself, or by his direction.

In the making of a will there are these several rules to be observed, viz. 1. That it be done while the testator is of sound mind and memory. 2. That there be two parts thereof, the one to remain in the hands of the party that made it; and the other in the custody of some friend, in order to render it less liable to be suppressed after the testator's death. 3. That the whole be written in one hand writing, and, if possible, in one sheet of paper or parchment. 4. In case there be more sheets than one, that the testator sign and seal every sheet, before the witnesses present at the execution.

WILL with a wisp, or *Jack with a lanthorn*, a meteor known among the people under these names, but more usually among authors under that of *ignis fatuus*. See *METEOR*.

This meteor is chiefly seen in summer nights, frequenting meadows, marshes, and other moist places. It seems to arise from a viscous exhalation, which being kindled in the air, reflects a sort of thin flame in the dark, without any sensible heat.

It is often found flying along rivers, hedges, &c. by reason it there meets with a stream of air to direct it. The *ignis fatuus*, says Sir Isaac Newton, is a vapour shining without heat; and there is the same difference between this vapour and flame, as between rotten wood shining without heat, and burning coals of fire.

WILLOW, *Salix*, in botany. See the article *SALIX*.

WIND, *Ventus*, in physiology, a stream of air flowing out of one place, or region, into another. See *AIR*.

As the air is a fluid, its natural state is that of rest, which it endeavours always to keep or retrieve by an universal equilibrium of all its parts. When, therefore, this natural equilibrium of the atmosphere happens by any means to be destroyed in any part, there necessarily follows a motion of all the circumjacent air towards that part to restore it; and this motion of the air is what we call wind.

Hence, with respect to that place where the equilibrium of the air is disturbed, we see the wind may blow from every point of the compass at the same time; and those who live northwards of that point, have a north-wind; those who live southwards, a south-wind; and so of the rest: but those who live on the spot, where all these winds meet and interfere, are oppressed with turbulent and boisterous weather, whirl-winds and hurricanes; with rain, tempest, lightning, thunder, &c. For sulphureous exhalations from the south, torrents of nitre from the north, and aqueous vapours from every part are there confusedly huddled, and violently blended together, and rarely fail to produce the phenomena above mentioned. See *RAIN*, *LIGHTNING*, &c.

Many are the particular causes which produce wind by interrupting the equipoise of the atmosphere; but the most general causes are two, viz. heat, which, by rarifying the air, makes it lighter in some places than it is in others; and cold, which, by condensing it, makes it heavier. Hence it is, that in all parts over the torrid zone, the air being more rarified by a greater quantity of solar rays, is much lighter than in any other parts of the atmosphere, and most of all over the equatorial parts of the earth. And since the parts at the equator are most rarified, which are near the sun; and those parts are, by the earth's diurnal rotation eastward, continually shifting to the west; it follows, that the parts of the air which lie on the west side of the point of the greatest rarefaction, and, by flowing towards

it, meet it, have less motion than those parts on the east side of the said point, which follow it; and therefore the motion of the eastern air would prevail against that of the western air, and so generate a continual east-wind, if this were all the effect of that rarefaction. But we are to consider, that as all the parts of the atmosphere are so greatly rarified over the equator, and all about the poles greatly condensed by extreme cold, this heavier air from either pole is constantly flowing towards the equator, to restore the ballance destroyed by the rarefaction and levity of the air over those regions: hence, in this respect alone, a constant north and south wind would be generated.

We find by experience, that people in general have but an obscure idea or confused notion of the cause of this perpetual current of air from east to west, or of a constant east wind under the equator. Therefore, in order to elucidate this matter, we shall explain it by a figure. Let C B A D E (plate CXL. fig. 4.) be part of a section of the atmosphere over the equator, C the east, E the west, A the point to which the sun S is vertical, and R the point of greatest rarefaction, or that where the air is most of all heated, and, consequently, lightest. That this point R is on the eastern side of the point A, is not difficult to be conceived, when what is said under the article *TIDE*, is well considered. And, because the air at R is by supposition lighter than where it is colder at C and D, it is plain that in order to obtain an equilibrium, which is necessary in a fluid body, the air by its greater weight will have a tendency from C and D towards R, and rise to a height there greater than at C or D, in proportion as its density is less.

Now this being the case, it is evident, the sun, being always between the points R and D, will be heating the air on that part: and those regions between R and C, having been deserted by the sun, will grow cold; consequently, the air between C and R, as it is colder, will likewise be heavier than that between R and D, which is hotter, and so will have a greater momentum, or quantity of motion, towards the point R; and since this point R is constantly moving after the point A westward, the motion of the western air towards it, will be in part diminished by that means; and being also inferior in quantity to the motion of the eastern air, the latter will prevail over it, and be constantly following the said point R from east to west, and thus produce a continual east wind.

It may, perhaps, be here said, that though the motion of the air be less from D to R, yet it is something, and so there ought to be a western wind, at least in some degree, and to some distance westward of the point R. To which we answer, that the nature of a fluid will not permit two contrary motions to restore or sustain an equilibrium, we mean in regard of the whole body of it; for wherever one part of the fluid is determined to move, all the rest must necessarily follow it; otherwise the equilibrium of the air would be destroyed in one part to make it good in another, a defect which nature cannot be guilty of. Thus, we see the tides of the ocean always follow the course of the moon from east to west, without any motion of the waters from the west towards the moon, in the open oceans; and the point R can only be considered as the aerial tide, or flood of high air; and has nearly the same phenomena with aqueous tides. See *TIDES*.

This being clearly understood, all the rest is easy; for no one can find it difficult to conceive how the cold air from each pole must necessarily set in towards the equator directly, where meeting and interfering with the eastern current, it does with that compound a new direction for the moving air which lies between both the former, viz. a north-east current on the north side, and a south-east on the south side: all which naturally results from the doctrine of the composition of oblique forces.

For the method of estimating the velocity of the wind, see the article *ANEMOMETER*.

Cardinal WINDS, are those which blow from the east, west, north, and south, which are called cardinal points.

Collateral WINDS, are those which blow between the cardinal points. The number of these is infinite, as the number of points they blow from are; a few of them

only are considered in practice, and these have names compounded of the cardinal points between which they blow. See the article COMPASS.

WIND, in the manege. A horse that carries in the wind, is one that tosses his nose as high as his ears, and does not carry handsomely. The difference between carrying in the wind, and beating upon the hand, is, that the horse who beats upon the hand, shakes his head, and resists the bridle; but he who carries in the wind, puts up his head without shaking, and only sometimes beats upon the hand. The opposite to carrying the wind, is arming and carrying low.

WIND-FLOWER, *Anemone*, in botany. See the article ANEMONE.

WIND-GALL, a name given by our farriers to a distemper of horses. In this case there are bladders full of a corrupt jelly, which, when let out, is thick, and of the colour of the yolk of an egg. They vary in size, but are more usually small than large. Their place is about the fetlock joint, and they grow indifferently on all four legs, and are often so painful, especially in the summer season, when the weather is hot, and the ground dry and hard, that they make the creature frequently stumble, or even fall down. The general method of cure is to open the swelling, about the length of a bean, and to press out the jelly: when this is done, they apply a mixture of the oil of bays, and the white of an egg, covering it with tow. Another method is, after the jelly is all squeezed out, to wrap round the part a wet woollen-cloth, and then applying a taylor's hot iron, this is to be rubbed over till the moisture is carried away; it is then to be daubed all over with pitch, mastich, and resin, boiled together, laying tow in plenty over all. The wind-galls that are situated near the sinews, are much the most painful of all, and soonest make the horse lame.

The general cause of wind-galls is supposed to be extreme work or exercise in hot weather; but it is to be observed, that those horses which have long joints, will be wind-galled if they work never so little. The worst wind-galls are those of the hinder legs; all the above-mentioned methods will frequently miss of success in these, and nothing but fire will cure them.

WIND-HATCH, in mining, a term used to express the place at which the ore is taken out of the mines.

WIND-MILL, a mill which receives its motion from the impulse of the wind.

The internal parts of a wind-mill are the same with those of a water-mill nearly, of which we shall take no farther notice, but shall confine ourselves to the theory of the sails in regard of their position, motion, and figure.

In regard of the position of the sails, we must consider that if they are placed direct to the wind, or at right angles to the axis of the mill, they will receive the whole force of the wind, which in this case will tend to blow them forward, and consequently to blow down the mill; which position of course cannot be admitted.

If the sails are set right to the wind, or parallel with the axis of the mill, it is plain that in that position the wind cannot act upon them at all, and therefore they cannot be turned round, nor the mill put into motion; which position of the sail must likewise be rejected.

Since neither the direct nor right position of the sails will do, an oblique position must, as there can be no other. Now to shew that an oblique position of the sails will turn the mill, let AB (plate CXL. fig. 5.) be the axis, CD a sail, and its angle of obliquity (viz. that which it makes with the axis) be ECG; then if GC be the force of the wind in the direct position of the sail, GE will be the force of the wind in its oblique position (as being the sine of the angle of incidence GCE.) But the force GE is resolvible into two others, EF and GF; of which the latter, being parallel to the axis, avails nothing in turning the sail about it; but the other, EF, being perpendicular thereto, is wholly spent in compelling the sail to turn round: which was the thing to be shewn.

The force of the wind on the sail will be as the square of the sine of incidence, or as $\overline{GE}^2$; for the force of each single particle of air will be as the sine GE

(fig. 6.) and it will be also as the number of particles which strike it at the same time, which number of particles is also as the sine of incidence GE. For let CD represent the section of the sail in a direct position, and CG the same in an oblique position, it is plain the number of particles striking it in the former case will be to the number striking it in the latter as CD to CF, which is equal to GE the sine of incidence; for all the particles between AD and BF will not come upon the sail in the oblique position CG. Since then the force of the wind on the sail is on two accounts as GE, it will be as the square of the said line GE. If we suppose the velocity of the wind to vary, the force thereof will be as the square of the velocity; for the greater the velocity, the greater will be the stroke of each single particle, and also the greater will be the number of particles coming upon the sail in the same time; the force will be therefore as the squares of the velocity.

Again, if the area of the sail be variable, the force of the wind will be directly as the area or superficies of the sail, because the number of particles of the air coming upon it will always be proportional thereto, and consequently the force with which they strike it. Hence if A, S and V represent the area, sine of incidence, and velocity of the wind on one sail, and a, s, v, those on another; the force compelling the former to turn round will be to that compelling the latter, as $A \times S^2 \times V^2$ to $a \times s^2 \times v^2$.

When the area of the sail and its position in respect of the wind continue the same, the force which turns the sail will be as the squares of the velocity; and since the wind scarce ever blows with one uniform velocity, but varies with almost every blast, the force upon the sail will be much more variable and unequal; and therefore the action or working of a wind-mill cannot be so equal, uniform, and steady as that of a water-mill, whose power is always of the same tenor, while the jet of water is so.

If the area of the sail and the velocity of the wind be supposed constant, the force of the wind in the direct position will be to that in the oblique one as $\overline{GC}^2$ to $\overline{GE}^2$, as we have before shewn; and it has also been shewn that that part of the force which turns the sail is represented by EF, when GE is the whole force; But $GE : EF$ ($:: GC : CE$) $:: \overline{GE}^2 : \frac{CE \times \overline{GE}^2}{GC}$ = to the force which turns the sail, when the whole force is represented by $\overline{GE}^2$, as is here the proper expression of it.

This expression $\frac{CE \times \overline{GE}^2}{GC}$ begins from nothing, when the angle of incidence begins to be oblique, and increases with the obliquity of the said angle to a certain number of degrees; because that part of the force which is parallel to the axis becomes lesser in proportion to that which is perpendicular to it; but after it has passed this limit, it again decreases, and becomes nothing, when the angle of incidence vanishes; as is easy to understand by considering that the quantity of wind on the sail does in this case continually decrease.

There is therefore one certain position of the sail, in which the force of the wind is greatest of all upon it, or a maximum; and to find it, put radius $GC = a$, $EC = x$, and we have $\overline{GE}^2 = a^2 - x^2$, and consequently the force $\frac{CE \times \overline{GE}^2}{GC} = \frac{aax - xxx}{a}$, which must be a maximum: Therefore its fluxion $aax - 3xxx = 0$; whence $aa = 3xx$, and so $x = \sqrt{\frac{aa}{3}}$, which

in logarithms is $\frac{20,000,000 - 0,477121}{2} = 9,761439$, which is the logarithm sine of the angle $35^\circ 16' =$ angle CGE; and therefore the angle ECG is equal to $45^\circ 44'$, when the force of the wind is a maximum, as required.

The angle now found, is only that which gives the wind the greatest force to put the sails in motion, but not the angle which gives the force of the wind a maximum

mum upon the sails when they have acquired some degree of velocity: to determine this last angle it will be necessary to premise the following lemma.

If a given angle $A C B$ (*fig. 7.*) be divided into two parts $A C E$, $E C B$, the product (or solid) contained under the square of the sine $E N$ of the one part $E C B$, and the sine $M E$ of the other, will be a maximum, when the sine of the difference of the parts is one-third of the sine of the whole given angle.

From E draw $Z E T$ perpendicular to the radius $C E$, and $E R$ parallel to $C B Z$. Put $C R = x$, $R E = y$, then $R T = \frac{-y \dot{x}}{y}$. Now because $y^2 x$ must be a max-

imum, we shall have $2y \dot{y} x + y y \dot{x} = 0$; hence $\frac{-y \dot{x}}{y} = 2x$; therefore, $R T = 2x$, and $T Z = 2 Z E$. Make $C S = C Z$, and draw $Z H$, $S P$ perpendicular to $C T$, then will $S P = \frac{1}{3} Z H$. Therefore $S P$, the sine of the difference of the angles $A C E$, $E C B$ to the radius $C Z$, is just one-third of $Z H$, the sine of the whole angle $A C B$ to the radius $C S = C Z$.

Let $A B C$ (*fig. 8.*) represent the plane of one of the sails of a wind-mill, $D B$ the direction and velocity of the wind perpendicular to $H B b$, the direction in which the sails turn round their axis. From D let fall $D E$ perpendicular upon $C A$ produced, and let $B b$ represent the velocity of the sails after they have been some time in motion; join $D b$, and draw $b e$ parallel to $B E$. Now it is well known that the efficacy of the wind upon the sails will be as $\overline{D e}^2 \times \text{sine } A B H$, or, which is the same thing, as $\text{sine } \overline{D b e}^2 \times \text{sine } b H$, which is (by the lemma) a maximum when the sine of the difference of the angles $D b e$, $D b H$ is equal to $\frac{1}{3}$ part of the sine of the whole given angle $B b D$: from whence the difference being given, the angles themselves will be known.

If the velocity of the sails be supposed $\frac{1}{8}$, or $\frac{1}{4}$ or $\frac{1}{2}$ of the velocity of the wind, or the ratio of $B b$ to $B D$ be as 1 to 8, 1 to 4, or 1 to 2, then the angle of inclination $A B D$ will be found from hence to be $58^\circ 14'$, $61^\circ 27'$, or $66^\circ 58'$, respectively; so that the greater the velocity of the plane is, the greater also will the angle of inclination be. Hence it appears that the sails of a windmill, that the effect may be the greatest, ought to be more turned towards the wind in the extreme parts, where the motion is swiftest, than in the parts nearer to the axis of motion, and that in a certain proportion not very difficult to ascertain from the above investigation.

Mr. Parent has also shewn that an elliptic form of the sails is better than the parallelogram or long square; and that the best position of the sail is not that which is common, viz. with its longest side or diameter parallel to the axis of the sail; but, on the contrary, it ought to be perpendicular to it; that is, they ought to be of such a form, and placed in such a manner, as represented in *fig. 9.* and after the four sails B, C, D, E , are thus placed on the axis or arm A , they are then to be turned about, and fixed under the proper angle of obliquity above-mentioned.

There are three things yet wanting to the perfection of a wind-mill. The first is, some contrivance in the nature of a fly to regulate the motion of the train, under the irregular and unequal impulse of the wind. The second is, some other contrivance to supply the hopper or stones with more or less corn, in proportion to the greater or less strength of the wind. And, thirdly, a method of altering the angle of the sail's obliquity from its maximum of $54^\circ 44'$ at the beginning of the motion, to its maximum when in motion.

WIND-SAILS, in a ship, are made of the common sail-cloth, and are usually between twenty-five and thirty feet long, according to the size of the ship, and are of the form of a cone ending obtusely: when they are made use of, they are hoisted by ropes to about two thirds or more of their height, with their basis distended circularly by hoops, and their apex hanging downwards in the hatch-ways of the ship; above each of these, one of the common sails is so disposed, that the greatest part of the

air rushing against it, is directed into the wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship.

WIND-SHOCK, a name given by our farmers to a distemperature to which fruit-trees, and sometimes timber trees, are subject. Mortimer is of opinion that the wind-shock is a sort of bruise and shiver throughout the whole substance of the tree; but that the bark being often not affected by it, it is not seen on the outside, while the inside is twisted round, and greatly injured. It is by some supposed to be occasioned by high winds; but others attribute it to lightning. Those trees are most usually affected by it, whose boughs grow more out on one side than on the other.

The best way of preventing this in valuable trees, is to take care, in the plantation, that they are sheltered well, and to cut them frequently in a regular manner, while young. The winds not only twist trees in this manner, but they often throw them wholly down: in this case the common method is to cut up the tree for firing, or other uses; but if it be a tree that is worth preserving, and it be not broken, but only torn up by the roots, it may be proper to raise it again, by the following method: let a hole be dug deep enough to receive its roots, in the place where they before were: let the straggling roots be cut off, and some of the branches, and part of the head of the tree; then let it be raised; and when the torn-up roots are replaced in the earth, in their natural situation, let them be well covered, and the hole filled up with rammed earth; the tree will, in this case, grow as well, and perhaps better, than before. If nature be left to herself, and the tree be not very large, the pulling off the roots will raise it.

WIND-TACKLE-BLOCKS, in a ship, are the main double blocks, which being made fast to the end of a small cable, serve for hoisting of goods into the ship, &c.

To WIND, or WEND a ship, signifies to bring her head about. *How winds or wends the ship?* is a question asked by mariners, concerning a ship under sail; signifying as much as, upon what point of the compass does she lie with her head?

WIND-TAUGHT, a sea-term, signifying as much as stiff in the wind. See the article TAUGHT.

Too much rigging, high masts, or any thing catching or holding wind aloft, is said to hold a ship wind-taught; by which they mean, that she stoops too much in her sailing in a stiff gale of wind. Again, when a ship rides in a main stress of wind and weather, they strike down her top-masts, and bring her yards down, which otherwise would hold too much wind, or be too much distended, or wind-taught.

WIND-WARD, in the sea language, denotes any thing towards that point from whence the wind blows, in respect of a ship: thus windward-tide, is the tide which runs against the wind. See TIDE, &c.

Large WIND. In the sea-language, to sail with a large wind, is the same as with a fair wind.

Side WIND, at sea, that which blows on the side of the ship.

WINDAGE of a gun, the difference between the diameter of the bore, and the diameter of the ball.

WINDASS, WANDASS, or WANLASS, an ancient term in hunting: thus, to drive the windlass, signifies the chasing a deer to a stand where one is ready, with a bow or gun, to shoot.

WINDER-MEB, in ornithology, the grey and white laurus, with a yellow beak.

This bird is of the size of our widgeon, and at a distance appears to be all over white; the head is remarkably large, and rounded; the ears are large, as also are the eyes, the iris of which is of a beautiful gold yellow, and the pupil black as jet; the beak is about an inch and a quarter long, considerably thick, very much arched and hooked, and pointed at the extremity; the chap is entirely yellow, and has a large protuberance; the legs are very slender and yellow; the thighs are naked half the way up; and the feet are webbed.

WINDING STAIRS. See STAIRS.

WINDLASS, or WINDLACE, a machine used to raise huge weights withal, as guns, stones, anchors, &c.

It

It is very simple, consisting only of an axis or roller, supported horizontally at the two ends, by two pieces of wood and a pulley: the two pieces of wood meet at top, being placed diagonally, so as to prop each other; the axis, or roller, goes through the two pieces, and turns in them. The pulley is fastened at top where the pieces join. Lastly, there are two staves or handspikes go through the roller, whereby it is turned, and the rope which comes over the pulley is wound off and on the same.

WINDLASS, in a ship, is an instrument in small ships, placed upon the deck, just abaft the foremast. It is made of a piece of timber six or eight feet square, in form of an axle-tree, whose length is placed horizontally upon two pieces of wood at the ends thereof, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for weighing anchors, or hoisting of any weight, in or out of the ship, and will purchase much more than any capstan, and that without any danger to those that heave; for if in heaving the windlass about, any of the handspikes should happen to break, the windlass would fall of itself.

WINDOW, *q. d.* wind-door, an aperture or open place in the wall of a house, to let in the wind and light.

We have various forms of windows, as, arched windows, circular windows, elliptical windows, square and flat windows, round windows, oval windows, Gothic windows, regular windows, rustic windows, and skylights.

The chief rules in regard to windows, are, 1. That they be as few in number, and as moderate in dimensions, as may consist with other due respects; inasmuch as all openings are weakenings. 2. That they be placed at a convenient distance from the angles, or corners of the building; because that part ought not to be enfeebled, whose office is to support and fasten all the rest of the building. 3. That care be taken that the windows are all equal one with another, in their rank and order; so that those on the right hand may answer to those on the left, and those above the right over those below; for this situation of windows will not only be handsome and uniform, but also the void being upon the void, and the full upon the full, it will be a great strengthening to the whole fabric.

As to their dimensions, care is to be taken not to give them more or less light than is needful; that is to make them no bigger, nor less, than is convenient; therefore, regard is to be had to the bigness of the rooms which are to receive the light: it is evident, that a great room needs more light, and, consequently, a greater window than a little room, and *à contra*. The apertures of windows, in middle-sized houses, may be four and a half or five feet, between the jaumbs, and in greater buildings six and a half, or seven feet, and their height may be double their length at the least. But in high rooms, or larger buildings, their height may be a third, a fourth, or a half breadth more than double their length. These are the proportions of the windows for the first story; and according to these must the upper stories be for breadth; but, as for height, they must diminish: the second story may be one third part lower than the first, and the third one fourth part lower than the second.

WINE, *Vinum*, a liquor made of the expressed juice of the grape, which, immediately after pressure, is called must, and being fermented becomes wine.

The goodness of wine consists in its being neat, dry, fine, bright, and brisk, without any taste of the soil, of a clean steady colour, having a strength without being heady, a body without being sour, and keeping without growing hard or eager. The difference of flavour, taste, colour, and body, in wines, is, perhaps, as much owing to the different manner and time of pressing, gathering, and fermenting the grape, as to any difference of the grape itself.

In Hungary, whence tockay and some of the richest and highest-flavoured wines come, they are extremely curious in these respects: for their prime and most delicate wines, the grape is suffered to continue upon the vine, till it is half dry by the heat of the sun; and if

the sun's heat should not prove sufficient, they are dried by the gentle heat of a furnace, and then picked one by one from the stalks; the juice of this grape, when pressed out, is of a fine flavour, and sweet as sugar; this, after due fermentation, is kept for a year, and then racked from the lees, when it proves a generous, oily, rich wine, and is sold at a very high rate. The Hungarians prepare a second sort of wine, by collecting together the better kind of grapes, carefully picking the fruit from the stalks, and then pressing out the juice: this is extremely sweet, and is made richer by infusing in it, after it has fermented for some days, a sufficient quantity of half-dried grapes. This wine, besides being very sweet, is oily, and of a grateful taste, and retains these qualities for a long time.

There is a third sort, made from the pure juice of this kind of grape, without any addition. This is a more brisk and lively wine, and far less sweet.

They likewise prepare a fourth sort, from grapes of different goodness mixed together; this, though not so generous, is nevertheless an excellent wine.

These Hungarian wines are remarkable for preserving their sweetness, and for the delicacy of their taste and smell; they, likewise, do not grow easily vapid, and may be kept in perfection for many years.

Wine being a liquor mostly of foreign produce, the divers names, forms, kinds, distinctions, &c. thereof, are borrowed from the countries where it is produced; the principal whereof, at this day, is France, to wines of which country, a good part of what we have to say of this noble liquor, will more immediately belong.

Wine in France is distinguished from the several degrees and steps of its preparation, into, 1. *Mere goutte*, mother drop, which is the virgin wine, or that which runs of itself out at the top of the vat wherein the grapes are laid, before the vintager enters to tread or stamp the grapes. 2. *Must*, *surmust*, or *stum*, which is the wine or liquor in the vat, after the grapes have been trod or stamped. 3. *Pressed wine*, being that squeezed with a press out of the grapes half bruised by the treading. The husks left of the grapes are called *rope*, *murk*, or *mark*, by throwing water upon which, and pressing them afresh, they make a liquor for servants use, answerable to our cyderkin, and called *boisson*, which is of some use in medicine, in the cure of disorders occasioned by viscid humours. 4. *Sweet wine*, is that which has not yet worked nor fermented. 5. *Bouru*, that which has been prevented working by casting in cold water. 6. *Worked wine*, that which has been let work in the vat to give it a colour. 7. *Boiled wine*, that which has had a boiling before it worked, and which by that means still retains its native sweetness. 8. *Strained wine*, that made by steeping dry grapes in water, and letting it ferment of itself.

Wines are also distinguished with regard to their colour, into white wine, red wine, claret wine, pale wine, rose or black wine; and with regard to their country, or the soil that produces them, into French wines, Spanish wines, Rhenish wines, Hungary wines, Greek wines, Canary wines, &c. and more particularly into Port wine, Madeira wine, &c.

Method of making, fining, &c. **WINE**. In the southern parts of France, their way is with red wines to tread or squeeze the grapes between the hands, and to let the whole stand, juice and husks, till the tincture be to their liking; after which they press it. But for the white wines, they press the grapes immediately; when pressed they tun the must and stop up the vessel, only leaving the depth of a foot or more to give room for it to work. At the end of ten days they fill this space with some other proper wine, that will not provoke it to work again. This they repeat from time to time, new wine spending itself a little before it comes to perfection.

The usual method of fining down wines, so as to render them expeditiously bright, clear, and fit for use, is this. Take an ounce of isinglass, beat it into thin shreds with a hammer, and dissolve it, by boiling, in a pint of water; this when cold becomes a stiff jelly. Whisk up some of this jelly into a froth with a little of the

the wine intended to be fined, then stir it well among the rest in the cask, and bung it down tight; by this means the wine will become bright in eight or ten days.

This method, however, is found to be best suited to the white wines; for the red ones, the wine-coopers commonly use the whites of eggs beat up to a froth, and mixed in the same manner with their wines.

They fine it down also by putting the shavings of green beech into the vessel, having first taken off all the rind, and boiled them an hour in water to extract their rankness, and afterwards dried them in the sun, or in an oven. A bushel of these serve for a tun of wine; and being mashed, they serve again and again, till almost quite consumed.

For English wine the method recommended by Mortimer, is first to gather the grapes when very dry, to pick them from the stalks, then to press them, and let the juice stand twenty-four hours in a vat covered. Afterwards to draw it off from the gross lees, and then put it up in a cask, and to add a pint or quart of strong red or white port to every gallon of juice, and let the whole work, bunging it up close, and letting it stand till January; then bottle it in dry weather. Bradley chuses to have the liquor, when pressed, stand with the husks, stalks, and all, in the vat, to ferment for fifteen days.

The method of converting white wine into red, so much practised by the modern wine coopers, Dr. Shaw observes is this. Put four ounces of turnsole rags into an earthen vessel, and pour upon them a pint of boiling water; cover the vessel close, and leave it to cool; strain off the liquor, which will be of a fine deep red, inclining to purple. A small portion of this colours a large quantity of wine. This tincture might be either made in brandy or mixed with it, or else made into a syrup, with sugar, for keeping. A common way with the wine-coopers is to infuse the rags cold in wine for a night or more, and then wring them out with their hands; but the inconveniency of this method is, that it gives the wine a disagreeable taste; or what is commonly called the taste of the rag; whence the wines thus coloured, usually pass among judges for pressed wines, which have all this taste from the canvas rags in which the lees are pressed.

The way of extracting the tincture, as here directed, is not attended with this inconvenience; but it loads the wine with water; and if made into a syrup, or mixed in brandy, it would load the wine with things not wanted, since the colour alone is required. Hence the colouring of wines has always its inconveniencies.

In those countries which do not produce the tinging grape, which affords a blood-red juice, wherewith the wines of France are often stained, in defect of this, the juice of elder-berries is used, and sometimes logwood is used at Oporto.

The colour afforded by the method here proposed, gives wine the tinge of the Bourdeaux-red, not the port; whence the foreign coopers are often distressed for want of a proper colouring for red wines in bad years. This might perhaps be supplied by an extract made by boiling stick-lack in water. The skins of tinging grapes might also be used, and the matter of the turnsole procured in a solid form, not imbibed in rags.

Stahl observes, that it is a common accident, and a disease in wines, to be kept too hot; which is not easy to cure when it has been of any long continuance, otherwise it may be cured by introducing a small artificial fermentation, that new ranges the parts of the wine, or rather recovers their former texture: but the actual exposing of wine to the fire, or the sun, presently disposes it to turn eager; and the making it boiling hot, is one of the quickest ways of expediting the process of making of vinegar. On the other hand, wine kept in a cool vault, and well secured from the external air, will preserve its texture intire in all the constituent parts, and sufficiently strong for many years, as appears not only from old wines, but other foreign fermented liquors, particularly those of China, prepared from a decoction of rice, which being well closed down in a vessel, and buried deep under ground, will continue for a long se-

ries of years, rich, generous, and good, as the histories of that country universally agree in assuring us.

The most general remedy hitherto known for all the diseases of wines, is a prudent use of tartarized spirit of wine, which not only enriches, but disposes all ordinary wines to grow fine.

WING, *Ala*, that part of a bird, insect, &c. whereby it is enabled to fly.

Willoughby observes, that all birds whatsoever have wings, or rudiments of wings, which answer to the fore-legs in quadrupeds. Among land fowl he observes, that the ostrich, cassowary, and dodo; and among water-fowl, the penguin, have wings altogether useless and unfit for flight.

Insects, indeed, have wings, and so have bats, but of a different kind from those of birds; the former being membranaceous, and the latter cutaneous: birds only have wings made up of feathers. All birds, towards the extremity of their wings, have a certain finger-like appendix, which is commonly called the secondary or bastard-wing. It is made up of four or five small feathers. Besides this, under the wing, or on the inside of the wing, some birds, especially water-fowl, have a row of feathers growing, called interior bastard-wing, which in most birds is of a white colour.

Reaumur observes, that wings among the fly-class, afford several subordinate distinctions of the genera of those animals, under the antient general classes. Several species of flies, while they are in a state of rest, or only walking, shew several regularly distinct manners of carrying their wings. The much greater number, however, carry them in a parallel or plain position. Among those who carry them thus, some have them in form of a sort of oars, their direction being perpendicular to the length of the body, which is not at all covered by them. Others carry their wings in this manner, so as that they cover a part of the body, without at all covering one another. The wings of others cross one another on the body of the creature, and the degrees in which they cover one another, give occasion to several other sub-distinctions; for some of them overhang on each side of the body of the animal, while others cross one another, in such a manner as not to cover the body of the fly entirely, but leave a rim of it visible and uncovered on each side of them. Some of the flies bred of water-worms, have their wings in this manner. Others have their wings thus disposed, but crossing one another only in a part of their surface, and that at their extremities; so that though they there cover the body of the fly, they leave a portion of the anterior part of the body naked.

The beautiful wings of butterflies are distinguished from those of the fly kind, by their not being thin and transparent, like them, but thicker and opaque. This opacity in them is only owing to the dust which comes off them, and sticks to the fingers in handling them; and it is also to this dust that they owe all their beautiful variety of colours. The earlier naturalists, for this reason, distinguished these insects by the appellation of such as had farinaceous wings.

The wings of gnats are of a very curious structure, and well worthy the use of the microscope, to see them distinctly. It is well known, that on touching the wings of butterflies, a coloured powder is left on the fingers, which, though to the naked eye it appears a mere shapeless dust, yet, when examined by the microscope, it is found to be very regularly figured beautiful bodies, in form of feathers and scales: these are of various figures, and all of them very elegant. The generality of flies have nothing of this kind; but the close examination of the wings of the gnat will shew, that they are not wholly destitute of them: they are much more sparingly bestowed, indeed, upon the gnat than on the butterfly; but then they are arranged with great regularity.

WINGS, in heraldry, are borne sometimes single, sometimes in pairs; in which case they are called conjoined. When the points are downward, they are said to be inverted; when up, elevated.

WING, in botany, the angle formed between the stem and the leaves or pedicles of the leaves of a plant.

WINGS, *Alæ*, in military affairs, are the two flanks or extremes of an army, ranged in form of a battle; being the right and left sides thereof.

WINGS, in fortification, denote the longer sides of horn-works, crown-works, tenailles, and the like out-works; including the ramparts and parapets, with which they are bounded on the right and left from their gorge to their front.

WINGED-LEAVES, in botany, are those which are composed of several folioli, or little leaves, ranged on each side the common footstalk like wings; but as these are disposed in different forms, so they have different appellations. See **PINNATE**.

WINGED-SEEDS, are those which are furnished with down or hairs, by the help of which they are buoyed up in the air, and carried a considerable distance; such are those of the dandelion, fowthistle, &c.

WINNOW, signifies to fan or separate corn from the chaff by the wind.

WINTER, one of the four seasons or quarters of the year.

Winter commences on the day when the sun's distance from the zenith of the place is greatest, and ends on the day when its distance is at a mean between the greatest and least.

Notwithstanding the coldness of the season, it is proved by astronomers, that the sun is really nearer the earth in winter than in summer.

Under the equator, the winter as well as other seasons, return twice every year; but all other places have only one winter in the year, which in the northern hemisphere begins when the sun is in the tropic of Capricorn, and in the southern hemisphere when in the tropic of Cancer; so that all places in the same hemisphere have their winter at the same time.

WINTER, among printers, that part of the printing press serving to sustain the carriage.

WINTER'S-BARK, *Cortex Winteranus*, in botany, a name given to the bark of the white or wild cinnamon tree.

The winter's bark is a thick and firm bark, though we have a different thing sometimes under its name: it comes to us rolled up in the manner of the common cinnamon, into a kind of tubes or pipes; but they are usually thicker, and always shorter than the fine tubes of cinnamon. It is externally of a greyish colour, and of a reddish brown within; it is properly indeed a double bark, the outer and inner of the same tree, not the inner bark alone, separated from the other, as the cinnamon and cassia are. The outer rind is of an uneven surface and of a loose texture, very brittle, and easily powdered. The inner bark, which has the principal virtue, is hard, and of a dusky reddish brown. The outer one is often cracked and open in several places, the inner one never in any. It is of an extremely fragrant and aromatic smell, and of a sharp, pungent, and aromatic taste, much hotter than cinnamon in the mouth, and leaving a more lasting flavour on it.

It is to be chosen in pieces not too large, with the inner or brown part sound and firm, and of a very sharp taste. It is apt to be worm-eaten; but in that case it is wholly to be rejected, as having lost the far greater part of its virtue.

The cortex Winteranus was wholly unknown to the ancients; the discovery of it among us is owing to Capt. Winter, who, in the year 1567, going as far as the Straights of Magellan with Sir Francis Drake, found this bark on that coast, and bringing a large quantity of it with him in his return to England, it became used in medicine, and was ever after called by his name. It is not, however, peculiar to the place he found it in, but is frequent in many parts of America.

The virtues of this bark were discovered by the English sailors on board captain Winter's ship; they first used it by way of spice to their foods, and afterwards for the scurvy. It is also good in palsies and rheumatisms; and a decoction of the leaves is good, by way of fomentation, for the parts externally affected by the scurvy. The

English sailors made it famous for its virtues against the poison of a certain fish, common about the Magellanic sea, which they called the sea-lion: they eat the flesh of this fish, and fell into many illnesses by it; among which was one attended with a peeling off of the skin of their whole bodies, not without excessive pain; this they remedied by the cortex Winteranus: but by the accounts we have of the effects of eating this fish, as it is called, they were rather symptoms of an inveterate scurvy, and, therefore, it is no wonder this bark did them great service.

WINTER-RIG, among husbandmen, signifies to fallow or till the land in winter.

WINTER-SOLSTICE. See the article **SOLSTICE**.

WINTERANA, in botany, a genus of plants, whose flower consists of five oblong sessile petals, with a conic, concave, pitcher shaped nectarium: the stamina hath no filaments, but consists of sixteen linear antheræ: the fruit is a roundish berry with three cells, each containing two heart-shaped seeds.

WIRE, a piece of metal drawn through the hole of an iron into a thread, of a fineness answerable to the hole it passed through.

Wires are frequently drawn so fine, as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron. Gold wire is made of cylindrical ingots of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller; till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes one of the distinguishing characters of gold, is no where more conspicuous, than in this gilt wire. A cylinder of forty-eight ounces of silver, covered with a coat of gold, only weighing one ounce, as Dr. Halley informs us, is usually drawn into a wire, two yards of which weigh no more than one grain; whence ninety-eight yards of the wire weigh no more than forty-nine grains, and one single grain of gold covers the ninety-eight yards; so that the thousandth part of a grain is above one-eighth of an inch long. The same author, computing the thickness of the skin of gold, found it to be $\frac{1}{11300}$ part of an inch. Yet so perfectly does it cover the silver, that even a microscope does not discover any appearance of the silver underneath. M. Rohault likewise observes, that a like cylinder of silver, covered with gold, two feet eight inches long, and two inches nine lines in circumference, is drawn into a wire 307200 feet long, i. e. into 115200 times its former length. Mr. Boyle relates, that eight grains of gold, covering a cylinder of silver, is commonly drawn into a wire 13000 feet long. See the articles **GOLD** and **DUCTILITY**.

Silver-wire is the same with gold-wire, except that the latter is gilt, or covered with gold, and the other is not.

There are also counterfeit gold and silver-wires; the first made of a cylinder of copper, silvered over, and then covered with gold; and the second of a like cylinder of copper, silvered over, and drawn through the iron, after the same manner as gold and silver-wire.

Brass-wire is drawn after the same manner as the former. Of this there are divers sizes, suited to the different kinds of works. The finest is used for the strings of musical instruments, as spinets, harpsichords, manichords, &c.

The pin-makers, likewise, use vast quantities of brass-wire, to make their pins of. Iron-wire is drawn of various sizes, from half an inch to one tenth of an inch diameter.

The first iron that runs from the stone, when melting, being the softest and toughest, is preserved to make wire of. Iron-wire is made from small bars of iron called esleom-iron, which are first drawn out to a greater length, and to about the thickness of one's little-finger, at a furnace, with a hammer gently moved by water. These thinner pieces are bored round, and put into a furnace to anneal for twelve hours. A pretty strong fire is used for this operation. After this they are laid under water for three or four months, the longer the better; then they are delivered to the workmen, called rippers, who draw

draw them into wire through two or three holes. After this they anneal them again for six hours, and water them a second time for about a week, and they are then delivered again to the rippers, who draw them into wire of the thickness of a large packthread. They are then annealed a third time, and then watered for a week longer, and delivered to the small wire-drawers, called over-house-men.

In the mill where this work is performed, there are several barrels hooped with iron, which have two hoops on their upper sides, on each whereof hang two links which stand across, and are fastened to the two ends of the tongs, which catch hold of the wire, and draw it through the hole. The axis on which the barrel moves does not run through the center, but is placed on one side, which is that on which the hooks are placed; and underneath there is fastened to the barrel a spoke of wood, which they call a swingle, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel, are by the workman fastened to the end of the wire, and by the force of the wheel, the hooks being pulled back, draw the wire through the holes. The plate in which the holes are, is iron on the outside, and steel on the inside; and the wire is anointed with train-oil, to make it run the easier.

WIRE of Lapland. The inhabitants of Lapland have a sort of shining, slender substance in use among them on several occasions, which is much of the thickness and appearance of our silver wire, and is therefore called, by those who do not examine its structure or substance, Lapland-wire. It is made of the sinews of the reindeer, which being carefully separated in the eating, are, by the women, after soaking in water, and beating, spun into a sort of thread, of admirable fineness and strength, when wrought to the smallest filaments; but, when larger, is very strong, and fit for the purposes of strength and force. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business, and the way they make it is to mill a piece of tin, and placing at the edge of it a horn with a hole through it, they draw these finewy threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a small piece of bone placed at the top of the hole, where the wire is made flat, so that we always find it rounded on all sides but one, where it is flat.

This wire they use in embroidering their cloaths as we do gold and silver; they often sell it to strangers, under the notion of its having certain magical virtues.

WISDOM, *Sapientia*, usually denotes a higher and more refined notion of things immediately presented to the mind, as it were, by intuition, without the assistance of ratiocination.

In this sense wisdom may be said to be a faculty of the mind, or at least a modification and habit thereof.

Sometimes the word is more immediately used, in a moral sense, for what we call prudence, or discretion, which consists in the soundness of the judgment, and a conduct answerable thereto.

WIT, a faculty of the mind, consisting, according to Mr. Locke, in the assembling and putting together of those ideas, with quickness and variety, in which any resemblance or congruity can be found, in order to form pleasant pictures and agreeable visions to the fancy. This faculty, the same author observes, is just the contrary of judgment, which consists in the separating carefully from one another such ideas wherein can be found the least difference, thereby to avoid being misled by similitude and affinity, to take one thing for another. It is the metaphor and allusion, wherein, for the most part, lies the entertainment and pleasantries of wit, which strikes so lively on the fancy, and is therefore so acceptable to all people, because its beauty appears at first sight, and there is required no labour of thought to examine what truth or reason there is in it. The mind, without looking any farther, rests satisfied with the agreeableness of the picture, and the gaiety of the imagination;

and it is a kind of affront to go about to examine it by the several rules of truth or reason.

WIT is also an appellation given to the person possessed of this faculty: and here the true wit must have a quick succession of pertinent ideas, and the ability of arranging and expressing them in a lively and entertaining manner; he must at the same time have a great deal of energy and delicacy in his sentiments; his imagination must be sprightly and agreeable, without any thing of parade or vanity in his discourse: but it is not, however, essential to the character of a wit, to be ever hunting after the brilliant, studying sprightly turns, and affecting to say nothing but what may strike and surprise.

WITCHCRAFT, a kind of sorcery, especially in women, in which it is ridiculously supposed that an old woman, by entering into a contract with the devil, is enabled, in many instances, to change the course of nature; to raise winds; perform actions that require more than human strength; and to afflict those who offend them with the sharpest pains, &c. In the times of ignorance and superstition, many severe laws were passed against witches, by which great numbers of innocent persons, distressed with poverty and age, were brought to a violent death; but these are now happily repealed.

WITENA-MOT, or WITENA-GEMOT, among our Saxon ancestors, was a term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliament.

WITHERS of a Horse, the juncture of the shoulder-bones at the bottom of the neck and mane, towards the upper part of the shoulder.

WITNESS, in law, a person who gives evidence in any cause, and is sworn to speak the truth, the whole truth, and nothing but the truth.

A witness ought to be indifferent with respect to each party; for if he will be a gainer or loser by the suit, he is not sworn as a witness.

False witnesses, suborners of witnesses, &c. are in England punished with the pillory; in several other countries with death.

WOAD, *Isatis*, in botany, a genus of plants, the flower of which consists of four leaves, which are disposed in form of a cross; out of whose flower-cup rises the pointal, which afterward turns to a fruit in the shape of a tongue, flat at the edges, gaping two ways, having but one cell; in which is contained, for the most part, one oblong seed.

Woad is commonly sown upon a lay, which they plow into high ridges, except the land be very dry; and they harrow the turf till they break it to pieces, and pick out all the grass, weeds, and lumps of earth, and fling them into the furrows to rot.

The land for this seed ought to be finely plowed and harrowed, and all the clods and turfs broken, and the stones picked up, and carried off.

The best time for sowing it is the latter end of July, soon after the seed is ripe; which will come up in August, and must be hoed out, as is practised for turneps, leaving the plants ten or twelve inches asunder; by which means they will grow strong, and produce much larger leaves; and besides, that sown at this season doth seldom miscarry; whereas that which is sown in the spring will be very liable thereto; and if it doth not, the plant will not have half the strength the first summer. It ought to be kept constantly weeded; but if it come up good, it will need the less weeding: the ordinary price of weeding is eight shillings per acre.

Some recommend the sowing of it about the beginning of February; for which they give this reason, that whereas it is apt to be spoiled by the fly and grub, it escapes the better being early sown; and if they do kill any of it, they have the better opportunity of sowing more.

They do this by making holes with a stick about seven or eight inches asunder, and put five or six seeds into each hole. They seldom or never sow it more than two years upon the same piece of land; because, if it be long continued, it robs the soil: but if it be moderately used, it prepares

prepares land for corn; and where the soil is rank, it abates the too great fertility of it.

It is ripe, when the leaf is come to its full growth, and retains its perfect colour and lively greenness; which is sometimes sooner, and sometimes later, as the year proves dry or moist. As soon as it is fit to cut, it should be done with all the speed that possibly may be, that it may not fade, or grow pale; and when it is cut, it ought to be immediately carried to the mill. The manner of doing which, and the way of ordering it, is best learned from experienced workmen, and is not to be trusted to a verbal description of it.

In plowing it up, and sowing it again, they pick up all the old roots, as they harrow it, except what they design for seed, which they let stand to the next year: it many times produces fifty quarters upon an acre.

They always keep a good quantity of seed by them, to plant the ground that fails; the seed of two years will sometimes grow; but as it is apt to fail, it is better to sow that of the first. And if they sow or plant it late, if the ground be dry and hard, they steep it in water the day before they sow it, which causes it to come up the sooner.

Good woad may yield five or six crops in a plentiful year; though it ordinarily yields but four, sometimes but three; especially if it be let stand to grow for seed: but what grows in winter they do not use, though it is very good and very cheap. The two first crops are the best, which are usually mixed in the seasoning. The latter crops are much the worse; which, if mixed with either of the former crops, spoil the whole.

It many times sells from six pounds to thirty pounds a ton, an acre commonly yielding about a ton. *Miller's Gard. Dict.*

WOULD, signifies a plain, down, or open champaign ground, hilly and void of wood.

WOLF, *Lupus*, in zoology, a very large and fierce animal, being equal to the biggest mastiff in size, and having much of the general appearance of that creature: the head is large and fleshy: the eyes are large and prominent, and their iris hazel: the ears are short, patulous, and erect: the teeth are very large, and the animal has a way of shewing them in a frightful manner, by grinning: the neck is robust and thick: the body is large, and the back broad: the legs are very robust: the tail is long and bushy: the natural colour is black, but there are some tawny; and in some places they are in winter perfectly white. The wolf is a very mischievous creature, destroying cattle; and in hard winters attacking houses and villages in whole troops.

WOLF'S BANE, in botany, the English name for the *aconitum*. See *ACONITE*.

WOLVES TEETH, of an horse, are over-grown grinders, the points of which being higher than the rest, prick his tongue and gums in feeding, so as to hinder his chewing. They are seldom met with in any besides young horses; but if they be not daily worn by chewing, they will grow up even to pierce the roof of the mouth.

WOMAN, *Fœmina*, in zoology, the female of man. See *MAN*.

WOMB, *Uterus*. See *UTERUS*.

WOOD, *Lignum*, a solid substance, of which the branches of trees consist, and deriving its growth from certain juices of the earth.

The structure and organisation of wood is a subject on which many have employed their thoughts; but perhaps none with greater success than the celebrated Monsieur Buffon, of the Royal Academy of Sciences at Paris.

This gentleman observes, that the organisation of wood is yet unknown in all its parts; and, that though the world is greatly indebted to the observations of Grew, Malpighi, and Hales, yet, when he entered on the subject, he found there was much more unknown than known, and determined to observe, from its first state, the growth of trees, and the formation of their woody part.

The seed of a tree, suppose an acorn, if put into the earth in the spring season, produces, after a few weeks, a tender shoot, of an herbaceous structure, which en-

larges, extends itself, and hardens by degrees, and, in the first year's growth, has in it a slender filament of a woody substance. At the extremity of this young tree there is a little button formed, which opens the next year into leaves, and from which there is propagated a second shoot, in all respects like that of the first year, except that it is more vigorous, grows faster, and hardens much more considerably. This is also terminated by a button like that of the precedent year; and in this is contained the shoot of the third year; and in this manner is the growth of the tree carried on, till it has acquired its whole height.

Each of these buttons is a sort of seed, which contains the shoot of the succeeding year, just as the seed itself did that of the first; and the growth of a tree in height is carried on, therefore, by a series of annual productions, exactly like one another; and the full grown tree is, though perhaps a hundred feet high, composed only of a number of short trees, joined end to end, the longest of which is not above two feet in length. These little trees of the several years never at all alter their height or length, or even their thickness; they remain even in a tree of a hundred years old, of their original length and diameter, and suffer no change, but in becoming harder. This then is the manner in which trees grow in height; how they grow in thickness is next to be inquired into.

The button which makes the summit of the tree of the first year, draws its nourishment through the very substance of that little tree; but the principal tubes or vessels which serve to convey the sap, are placed between the bark and the woody filament.

The action of this sap, in moving, dilates and enlarges these vessels, while the button, in raising itself up in growth, elongates them; the sap also, in continually passing them, leaves behind it certain fixed parts, which augment the solidity. Thus the second year's little tree contains in its middle a woody filament in form of an elongated cone, which is the production of the wood of a former year, and a woody bed for it, which is also of a conic shape, and which surrounds the first filament, and reaches beyond it in length; and this is the production of the second year. The third bed forms itself altogether like the second, and all the succeeding ones are formed by the same law, and in the same order, and envelope one another in a continued succession or series, so that a large tree is composed of a number of woody cones, which enfold, cover, and envelope one another, as the tree increases in thickness.

When the tree comes to be cut down, one easily counts, in a transverse section of the trunk, the number of these cones, the section of which make so many concentric circles; and the age of the tree is known by the number of these circles, for they are distinctly separate from one another; in a vigorous and well grown oak, these lines are each of a sixth of an inch or more in thickness, and the substance of these lines or circles is very hard and firm, but the substance of the wood, which lies between, and unites these together, is much less so. This intermediate matter is always the weak part of the wood, and its structure and organisation is perfectly different from that of the woody cones, and depends entirely on the manner in which these cones are united to one another. This is explained in the following manner:

The vessels, which are longitudinally disposed in the wood, and convey the nourishment to the bottom, not only are extended and hardened by the action of the sap in motion, and by the firm particles it deposits; but they are ever attempting also an extension of another kind; they are ramified all along as they go, and break into numberless extremely minute filaments, which issue from them like so many branches; these, on the one part, are destined to the production of the bark of the tree; and, on the other, are connected to the wood of the preceding year, and from between the two woody beds, a sort of spongy reticular work, which, when cut transversely, even to a great thickness, shews numberless little cavities and holes, resembling a sort of lace-work. The woody beds are therefore united to one another by a sort of net-work; this net-work, however,

does not occupy nearly the space of the woody circles which it separated, and is usually indeed but about the sixth part of their thickness. This thickness is much the same in all the trees of the same species, whereas the woody beds vary in them very considerably in thickness: in the oak they are found from a sixth to a four and twentieth part of an inch in thickness.

By this easy exposition of the texture of wood, it is easy to discover that the longitudinal coherence of the particles of it must needs be vastly greater than the transverse: one sees also that, in little pieces of wood, as in a bar of an inch thickness, if there are fourteen or fifteen of these woody beds, there will also be thirteen or fourteen of these intermediate spaces; and consequently it will be much weaker than if there were but five or six of these woody beds in it, and consequently but four or five of these intermediate spaces.

It may also be observed, that in those little bars of wood there are two or three of the woody beds wounded, which is often the case; the strength of the bar must be thence greatly impaired: but the greatest fault these small pieces of wood are subject to, is the different disposition of these beds in the different parts of the same tree; and this difference is so great, that the force or strength of a large beam of any wood cannot be computed by proportion, from that of a small piece of the same wood; which, were it possible, would make calculations of this kind extremely easy. The ingenious author of this paper has from hence calculated the force and strength of timber used in building. *Memoires Acad. Par.* 1740.

The people who work much in wood, and that about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down, and that not regularly the same in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear tree, cut in summer, works hardest: holly, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about Easter; hawthorn works mellow when cut about October, and the service is always tough, if cut in summer.

Mortimer observes, that all kinds of wood are to be preserved from the worm, and from many other occasions of decay, by oily substances, particularly the essential oils of vegetables. Oil of spike is excellent; and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will preserve tables, instruments, &c. from being eaten to pieces by these vermin; and linseed-oil will serve, in many cases, to the same purpose: probably nut-oil will do also, and this is a sweeter oil, and a better varnish for wood.

Some of the West-Indian trees afford a sort of timber, which, if it would answer in point of size, would have great advantages over any of the European wood in ship-building for the merchant-service, no worm ever touching this timber. The acajou, or tree which produces the cashew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the white-wood, which has exactly the same property: and so have many other of these trees.

To season wood expeditiously for sea-service, Mr. Boyle observes, that it has been usual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a desideratum in the art of carving. He says, he had been credibly informed of its having been practised at the Hague; and suspects that it might have been performed by some menstruum that softens the wood, and afterwards allows it to harden again, in the manner that tortoise-shell is moulded: or, perhaps, by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that having mixed saw-dust with a fine glue made of ising-glass, slightly straining out what was superfluous through a piece of linen, the remainder, formed into a ball and dried, became so hard as to rebound when thrown against the floor.

Wood used for fuel is required of various kinds, in regard to the various works to be performed by it.

Neri every where commends oak for the wood to be burnt in the glass-houses, as the properest wood for making a strong and durable fire with a good flame.

Imperato, on the contrary, recommends ash on the same occasion; because, as he says, it gives a substantial, rather than a great flame: and Camerarius deservedly commends juniper wood, as affording a lasting, strong, and sweet fire, could plenty of it be had. Among the ancients, Pliny commends light dry wood; and Plutarch, the tamarisk in particular, for making the glass-house-fires; but glass-making requires so great a fire as cannot be easily made with wood. Nor can ash be proper, because, though it gives a good fire, it soon decays.

Woods are distinguished into divers kinds, with regard to their nature, properties, virtues, and uses. Of wood, considered according to its qualities, whether useful, curious, medicinal, &c. the principal is called timber, used in building houses, laying floors, roofs, machines, &c. See TIMBER.

The medicinal woods are guaiacum, aloes, saffrafras, nephriticum, fantal, sarsaparilla, aspalathum, &c.

Woods used in dying are the Indian wood, Brazil wood, Campeachy wood, &c.

Fossile Wood. Fossile wood, or whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth; and sometimes in small pieces loose among gravel. These, according to the time they have lain in the earth, or the matter they have lain among, and in the way of, are found differently altered from their original state; some of them having suffered very little change, and others being so highly impregnated with crystalline, sparry, pyritical, or other extraneous matter, as to appear mere masses of stone, or lumps of the common matter of the pyrites, &c. of the dimensions, and, more or less, of the internal figure of the vegetable bodies into the pores of which they have made their way.

The fossile woods which we find at this day, are, according to these differences, arranged, by Dr. Hill, into three kinds; 1. the less altered; 2. the pyritical; and, 3. the petrified.

Of the trees, or parts of them, less altered from their original state, the greatest store is found in digging to small depths in bogs, and among what is called peat or turf-earth, a substance used in many parts of the kingdom for fuel. In digging among this, usually very near the surface, they find immense quantities of vegetable matter buried, and that of various kinds: in some places there are whole trees scarce altered, except in colour; the oaks in particular being usually turned to a jetty black; the pines and firs, which are also very frequent, are less altered, and are as inflammable as ever, and often contain, between the bark and wood, a black resin. Large parts of trees have also been not unfrequently met with unaltered in beds of another kind, and at much greater depths, as in the strata of clay and loam, among gravel, and sometimes even in solid stone.

Besides these harder parts of trees, there are frequently found also in peat-earth vast quantities of leaves and fruit, and catkins of the hazel, and the like trees: these are usually intermixed among the sedge and roots of grass, and are scarce at all altered from their usual texture. The most common of these are hazel nuts; but there are frequently found also the twigs and leaves of the white poplar; and a little deeper usually there lies a cracked and shattered wood, the crevices of which are full of a bituminous black matter; and among this the stones of plums, and other stone-fruits, are sometimes found, but that more rarely.

The irregular masses or fragments of wood are principally of oak, and are most usually found among gravel, though sometimes in other strata. These are variously altered by the insinuation of crystalline and stony particles, and make a very beautiful figure when cut and polished, as they usually keep the regular grain of the wood, and shew exactly the several circles which mark the different years growth. These, according to the different matter which has filled their pores, assume various colours, and the appearance of the various fossils that

have impregnated them; some are perfectly white, and but moderately hard; others of a brownish black, or perfectly black, and much harder; others of a reddish black, others yellowish, and others greyish, and some of a ferrugineous colour. They are of different weights also and hardneses, according to the nature and quantity of the stony particles they contain: of these some pieces have been found with every pore filled with pure pellucid crystal; and others in large masses, part of which is wholly petrified and seems mere stone, while the rest is crumbly and is unaltered wood. That this alteration is made in wood, even at this time, is also abundantly proved by the instances of wood being put into the hollows of mines, as props and supports to the roofs, which is found after a number of years as truly petrified as that which is dug up from the natural strata of the earth. In the pieces of petrified wood found in Germany, there are frequently veins of spar or of pure crystal, sometimes of earthy substances, and often of the matter of the common pebbles: these fragments of wood sometimes have the appearance of parts of the branches of trees in their natural state; but more frequently they resemble pieces of broken boards; these are usually capable of a high and elegant polish.

Many substances, it is certain, have been preserved in the cabinets of collectors, under the title of petrified wood, which have very little right to that name. But where the whole outer figure of the wood, the exact lineaments of the bark, or the fibrose or fistular texture of the stræ, and the vestiges of the utriculi and tracheæ, or air-vessels, are yet remaining, and the several circles yet visible, which denoted the several years growth of the tree, none can deny these substances to be real fossil wood.

Wood, *Sylva*, in geography, a multitude of trees extended over a large continued tract of land, and propagated without culture. The generality of woods only consist of trees of one kind.

The ancient Saxons had such a veneration for woods, that they made them sanctuaries.

It is ordained, that none shall destroy any wood, by turning it into tillage or pasture, &c. where there are two acres or more in quantity, on pain of forfeiting 40 s. an acre, by 35 Hen. VIII. c. 17. All woods that are felled at fourteen years growth, are to be preserved from destruction for eight years; and no cattle put into the ground till five years after the felling thereof, &c. 13. Eliz. c. 25. The burning of woods, or under-wood, is declared to be felony; also those persons that maliciously cut or spoil timber-trees, or any fruit-trees, &c. shall be sent to the house of correction, there to be kept three months, and whipt once a month.

WOOD-COCK, *Scolopax*, in ornithology. See **SCOLOPAX**.

The wood-cock is a bird of passage, that comes into England about the middle of October, and goes away again in March. During their stay with us, they ramble about from place to place, never remaining above eight or ten days together in the same wood or meadow. They seldom or never fly in the day-time, unless disturbed by men, or by some beast. In whatever places they are put up, they always fly to the thickest wood that lies near, and there hide themselves under the sturdiest and the thickest trees, where they remain all day searching for earth-worms, and other food, under the fallen leaves.

When night comes, they go out of the woods, and generally resort to watery places, where they may wash their bills, fouled with the taking their prey, and thrusting into the earth; here they remain all the night, and, if there is tolerable shelter, they stay also the day under it; but when there wants this, they fly away to the woods in the morning. In their flight, they choose the shadiest places, and will coast it away to a great distance in search of the highest woods to retire to, that they may be the better secured, and there more defended from the annoyance of the wind. While they travel under shelter, they always fly low; but when they come to any glade or cross, they mount to a considerable height; but, as soon as they have passed this, they sink again.

They hate flying high, and they are afraid to fly among trees, because, like the hare, they see but very badly straight before them; and it is owing to this imperfection in their sight, that they are so easily taken in nets spread in their places of resort.

The draw-net, in countries which are very woody, is extremely profitable in this sport, it being no uncommon thing to take ten or a dozen wood-cocks at a time in it.

The method of using it to advantage is this: there must be chosen a proper place in some thick wood, where these birds are found to resort, and a place must be cleared for them, and for the net. Supposing the wood about three hundred paces long, in this case, towards the middle there must be cut a walk through it eight fathoms wide: near the end of this, two opposite trees are to be pitched upon, proper to support the two sides of the net; the boughs of these are to be all cleared away, and the nets fastened by logs and pullies.

When the net is thus placed, the sportsman must provide some covert in which he must stand concealed. This is easily made by half a dozen boughs of ever-green trees with their leaves; and the sportsman, when he has fluck these down in the ground, and interwoven their boughs together, may either stand behind it, or sit down on a bundle of dry fern, or any other such matter. At three or four feet distance from this stand, towards the net, there is to be a strong stake fastened into the ground, and on this the lines of the net are to be fastened when it is drawn up. When there comes a wood-cock, the net is to be let down as soon as ever he is taken, to entangle him the more, for, otherwise, in the struggling he may chance to make his escape. The sportsman is then to run up, and break a wing, and crush his head. The net is then to be refitted again as quick as possible; for when one is caught, there is great reason to suspect that many more are coming the same way, which will be all lost, if the sportsman is slow at his work.

If a hare, or any other creature worth the taking, come along the walk, the net is not to be immediately let down upon it, for in that case it would certainly start back, or run forwards, and in either case it would probably make its escape: the net is to be drawn up five or six feet, that he may pass quietly under it without suspicion; as soon as he is gone by, the sportsman is to make a great shout, and let go the net; the creature will, on this noise, start back, and will thus be certainly taken in the net.

There are in many places, great throughfares through some open piece of ground, by which woodcocks pass in great numbers from one wood to another. If there be in these two trees, naturally planted, so as to sustain the nets, they are by all means to be used; but, if not, the sportsman will find it worth his while to be at the expence of planting two trees deep in the earth, at proper distances, that they may stand all weathers. Nets spread between these are the most fatal of all others to these birds, for all that inhabit either one or the other of the woods come this way at times, without suspicion of any danger or disturbance.

There is another method of taking these birds in high woods, with those nets called hays, of the nature of the rabbit-hays, only with smaller meshes. The woodcocks are driven only into these, and there should always be at least two or three of them planted together. When the sportsman has provided himself with nets, he is to take five or six persons into the wood with him. The proper woods for this purpose are those of seven or eight years growth; and the people are to go into some part of them, near the middle. The nets or hays are to be placed in the same manner as they are for taking of rabbits, but two or three joining together at the end, and hanging over slopewise that way which the wood-cocks are intended to be driven.

The nets being thus fixed, let the company go to the end of the wood, placing themselves at about ten rods distance from one another; they must all have sticks in their hands, and they are to move forwards slowly towards the nets, making a noise by striking the sticks against the trees and branches, and by hallooing with their voices:

voices: in this manner they are to move up to the net; and the wood-cocks in that part of the wood will all be terrified before them, but will not take wing, but run along upon the ground, and thus be driven along like a drove of beasts, so that, when the company come up, they will find almost all of them in the net. When that part of the wood is thus drove, the nets are to be turned the other way, and placed slopewise in the contrary direction, and the company, retiring to the other end of the wood, are to drive the woodcocks that are in that part with the same noise, till they have sent them into the nets in the same manner.

Thus all the wood-cocks in the wood may be taken with very little trouble, and this may be done equally at any time of the day.

Another way of taking this bird is, by means of nooses or springs.

The wood-cock and the snipe are both easily taken also with bird-lime, when their places of resort are known, but they are not so easily found as many other birds.

The custom of the woodcock is usually to be upon the banks under hedges, and by the sides of ditches towards the sun; and they will suffer the sportsman to come nearer them in the day-time after a moon-shiny night, than after a dark one. The reason of which is, that, having fed well by moon-light, they are only fit for rest in the day following; but, when the night has been dark, they are seeking food all the day long.

The snipes naturally lie by the sides of rivers, when the plasnes and ponds are frozen, and they always lie with their heads up or down the stream, never transversely.

In order to take either of these birds by bird-lime, the sportsman must be provided with a large number of small and smooth twigs, neatly and evenly covered with good bird-lime. These must be placed sloping, some one way, some another, and the whole place about where they resort must be covered with them. The sportsman then must conceal himself very carefully, that the sight of him may not frighten away the game.

WOODCOCK SHELL, in natural history, the variegated yellowish purpura, with tubercles, and a long beak; and the thorny woodcock shell is the yellow long beaked purpura, with long and crooked spines.

WOOD-CORN, is said to be corn given by the tenants of some manors to the lords for the liberty to gather up wood, and the feeding of cattle there.

WOON and WOOD, in the sea language, is when two pieces of timber are so let into each other, that the wood of the one joins close to the other.

WOOD-LAND, in agriculture, a term used by the farmers of many counties of England, for a sort of soil, from its constant humidity and dark colour, resembling the soil in woods, which, of whatever nature it originally is, will always be made to appear thus from the continual dropping of trees, and the want of a free air and sun, together with the fall of leaves, destroyed and washed to pieces by the wet.

This soil in the open countries has a considerable quantity of clay in it, and holds the water a long time that once falls upon it: in wet weather it sticks firmly to the plough-share, and, in dry, is very apt to crack. In uncultivated places it usually produces rushes and rush-grass. A moist and dripping year is extremely detrimental to this sort of land.

WOOD-LARK, in ornithology. This is one of the sweetest of our singing-birds, and is indeed very little inferior to the nightingale, when in good health: for we are not to judge by such as are made feeble by improper food, or want of cleanliness in their cages.

It is one of the tenderest birds we have, and yet it breeds the soonest of any that we know of. They principally frequent gravelly grounds, and the sides of hills, that are exposed full to the sun; and, if there be any stumps of oaks in these places, they always resort to them.

The females couple with the males in the beginning of February, at which time, and never before, they part

with their last year's brood; immediately after coupling, they betake themselves to building their nest.

They generally build in lay, or grounds where the grass is rank, and is grown brown. The principal material they use is dry grass, and they always chuse some place sheltered by a good tuft for their nest, to defend themselves from the cold winds, which are very severe at that season. They feed their young principally with a small red worm; but it is very difficult to find this kind, to feed a nest of them under our care, and they will not do well without it; so that they scarce ever come to any thing this way.

WOOD-MITE, in natural history, the name of a little animal frequently made the subject of microscopical observation, and by some called the wood-louse; though that less properly, as there is another larger animal generally known by that name.

The wood-mite is in shape and colour very like a louse, and is frequently found running very nimbly, but always by starts and jumps, on old books and rotten wood. The eyes of this creature are of a fine gold colour, and can be thrust out or drawn in at pleasure; and when examined by the microscope, the peristaltic motion of the guts is seen very distinctly and beautifully; and, what is more wonderful, there is observed a very distinct and regular motion in the brain.

This probably is the same animal with the pediculus pulsatorius, described by Derham, as one of the death-watches. *Baker's Microscope.*

WOOD-PECKER, *Picus*, in natural history, a genus of birds, with the beak straight, of a polyhedral or many-sided figure, and with its point formed in the manner of a wedge; the tongue is rounded and very long, it resembles in form a worm, or some other such insect; the toes, in all but one species, stand two before, and two behind, as in the parrot. This genus comprehends the great black wood-pecker, with a scarlet head, in size somewhat larger than that of a fieldfare; the green wood-pecker, with a scarlet crown; the great spotted wood-pecker, with a black head, and some of the tail-feathers white; the lesser spotted wood-pecker, with three lateral rectrices, half black; the three-toed wood-pecker, with only three toes; the Brazilian wood-pecker, or ipecu, with a scarlet crested head; and the golden wood-pecker, or the yellow picus. There are various other species of wood-peckers, as the brown picus, spotted with yellow; the black picus, with the wings and tail yellow, &c.

WOODWARD, an officer of the forest, whose function is to look after the woods, and observe any offences either in vert or in venison, committed within his charge, and to present the same; and in case any deer are found killed, or hurt, to inform the verderer thereof, and to present them at the next court of the forest.

WOOF, among manufacturers, the threads which the weavers shoot across with an instrument called a shuttle.

The woof is of different matter, according to the piece to be wrought. In taffety, both woof and warp are silk. In mohairs, the woof is usually wool and the warp silk. In satins, the warp is frequently flax, and the woof silk. See WARP and WEAVING.

WOOL, *Lana*, the covering of sheep; of which the manufacturers make divers kinds of stuffs, cloths, &c.

The wools most esteemed are the English, chiefly those about Leominster, Cotswold, and the Isle of Wight; the Spanish principally, about Segovia, and the French about Berry, which last are said to have this peculiar property, that they will knot or bind with any other sort, whereas the rest will only knot with their own kind. Tavernier affirms, that the wools in Asia, are incomparably finer than those of Europe; and there is no doubt but that wool was the golden fleece sought at Colchis. The wools of England have always been in the highest repute, especially abroad. Spanish wools bear a great price among us, to work up with ours, the goodness of which is owing to a few sheep sent into Spain, as a present, by Henry II. though some say by Henry IV. in 1465.

The fineness and plenty of our wool is owing in a great measure to the short sweet grass in many of our pastures and downs; though the advantage of our sheep's feeding on this grass all the year, without being obliged to be shut up under cover during the winter, or to secure them from wolves at other times, contributes not a little to it.

Antiently, the principal commerce of the nation consisted in wool unmanufactured; which foreigners, especially the French, Dutch, and Flemish, bought of us, insomuch, that the customs paid on wool exported in the reign of Edward III. amounted, at 50 s. a pack, to 250,000 l. per annum. An immense sum in those days! But as wool is now accounted a staple commodity, the employment of an infinite number of people at home, and our most beneficial trade abroad, depending upon it, very severe laws have been made to prevent its being exported, and persons that export wool beyond the seas, are liable to a forfeiture of the ships or vessels in which it is found, with treble the value, and the persons aiding and assisting in it shall suffer three years imprisonment. It is also enacted, that no sheep shall be carried on board any ship with intent to be exported, upon forfeiture of 20 s. for every sheep; that the owners knowing thereof, are to forfeit their interest therein; that if they be aliens, or natural-born subjects not inhabiting this kingdom, such ships shall be wholly forfeited; that the masters and mariners knowing thereof, and assisting therein, are to forfeit all their goods and chattels, and to suffer three months imprisonment; and that the exporter, besides other penalties, shall be rendered incapable of suing for any debt, &c. As to the importation of wool, Irish wool, combed or uncombed, Spanish and Polish wool may be imported duty free.

Wool is also used for the soft hair growing on several wild beasts, the skins of which are distinguished by the name of furs.

WOOLEN MANUFACTORY, includes the several sorts of commodities into which wool is wrought.

The woollen manufactory makes the principal article in the foreign and domestic trade of Great Britain. It employs the chief of the hands on shore, in its different parts; loads their ships, and brings into the nation the immense riches for which our nation is, at present, so remarkably famous.

This staple, however, did not fix itself on this island, till about the year 1420, when the art of making woollen cloths was imported from Flanders and Brabant, whose artists in that commodity, being driven from their native countries by oppressive taxes, and the severities used in collecting them, took refuge in England. The government spared no endeavours to preserve so valuable an acquisition; but we do not find our nation arrive at any considerable perfection in the woollen manufacture, till the troubles about religion, occasioned by the cruelty of the duke of Alva, and the Spanish inquisition introduced into the Low-Countries, entirely ruined those woollen manufacturers who had settled there, and greatly interfered with the trade established in England. At this time the Dutch artists also joined us, and settled several great manufactures at Norwich, Colchester, Sandwich, Hampton, as well as at London, &c. And from that time this trade throve so prodigiously, that Dr. Davenant and Mr. King compute the product thereof in their time, when it was not at the height it is now brought to, to be eight millions sterling, per annum: three-fourths of which, say they, are consumed at home, and the rest abroad.

Method of weaving, thickening, fulling, &c. Cloth. Before the warp is mounted, the threads are stiffened with a size made of shreds of parchment, or gum-water; when dry, the weavers mount their looms in the following manner: in those places where the most beautiful thin stuffs are made, it is the common custom to place eighteen threads upon the pegs of the loom. The going back over all the pegs, and the bringing back and return of them, on all the same again, produce the first assemblage of thirty-six threads, which is called a hand-ful. And forty of these are required to compleat that bundle which is termed a chain. So that a chain, in

weaving, contains 1440 threads, which multiplied by 12 ells, the usual length of each thread, the sum will be 17280 ells of thread. Then the artist, to render this bundle of long thread manageable and portable, rounds the ends thereof into a great loop, through which he thrusts his arm, and carries on it the bundle of threads. Then he makes a second, and as many more links on it as convenient. And hence the long assemblages of warp threads, looped up, and shortened into a small compass, take the name of the chain; a name they afterwards retain, even when extended on the loom to receive the cross thread or woof. But several of these chains must go to form the mounting of a stuff, or that first basis of long threads which are extended, parallel, from one end of the loom to the other. They are there received and rolled upon the beam: and as fast as they are converted into stuff, or cloth, by the throwing in of the woof, the stuff or cloth is rolled upon the other wooden cylinder that lies before the workman under the play of the shuttle.

The warp being on the loom, the weavers, who are employed in broad works, attend two to each loom, one on each side, and tread at the same time alternately, on the same treddle, that is, now on the right step, and now on the left, which raises and lowers the threads of the warp equally; between which they throw transversely, the shuttle from one to the other: and each time that a shuttle is thrown, and so a thread of the woof inserted within the warp, they strike it conjointly with the same frame wherein is fastened the comb, or reed, between whose teeth the threads of the warp are passed; repeating the stroke as often as is necessary, sometimes no less than twelve, or thirteen times, viz. six with the warp open, and seven with it shut. The closer the threads of the woof are struck against each other, the closer the cloth will be; and better enabled to bear the violence of the fulling-mill, as well as of the teazel and fulling-thistle, without opening or fretting. When the whole warp is filled, the cloth is finished: and it is taken from the loom by unrolling it from the beam whereon it had been rolled, in proportion as it was wove; and now given to be cleared of the knots, ends of threads, straws, and other filth; which is done with little iron nippers.

When a stuff or cloth is intended to be thickened, and to be more or less nappy, it is carried to the fulling-mill to thicken its warp, by strongly pressing the hairs of the woof, which are always found, in some degree, after weaving, be the wool never so fine; and being fastened within the body of the stuff, stand with their sharp end outwards.—It is the fuller, who, properly speaking, gives the cloths their real substance: his art being to add the advantage of felting to the regularity of weaving, and to cleanse the stuff perfectly. None but cloths require the first operation; all cloths and stuffs require the latter. The first is performed by a mill, in which the cloths are beaten by hammers, while the water runs continually over them, till they are reduced to their proper breadth, and thoroughly cleansed from all impurities. The second is no more than a dry beating, after the stuff has been judiciously smeared with fullers-earth, which is an absorbent matter, proper to extract all the unctuous juices: and, as occasion serves, they wash the most tenacious particles away with clear water. By repeating this several times, the most dirty cloths and stuffs are cleansed from the earth, oil, impurities of dyeing, &c.

Besides the variety which proceeds from the choice, the mixture, the preparation and working of the materials, the manufacture may be further diversified by finishing or not finishing it in this or that manner, after the goods are really made. For they change their names, according to the manner, in which they pass through the hands of the fuller, and are ornamented or dressed.

First it is knotted, or rather cleared from all its knots, little straws, and exuberances, by the help of sheers and birchen whisks; for if the least hard body should be left upon a cloth or piece of stuff, it would, in great likelihood, make a hole, while in the fuller's stock or pot; from whose hand it returns again to the knoter, who carefully turns it over a second time, and with great exactness picks out all the earthy, and other substances,

that remain, or had been overlooked, and might alter the colour, or otherwise damage the goods.

After this second examination, the cloth or stuff is sent again to the fulling-house, where it is perfectly cleansed with hot water and sope. When the water runs out of the stock as clear as it went in, then they leave off watering it to beat it dry. If the stuff or cloth has been felted or milled, they take care to unfold it every two hours, and pull it by its edges, as well to get out the creases contracted in the mill, as to prevent its too great shrinking; and, after that, wash it once more in fair water.

The next operation is that of carding, thistling, or teasing the goods. A tease, by some called a thistle, is a kind of wire brush, not unlike the head of a thistle, with an iron handle; every point of which terminates in a very sharp hook.—In this work they moisten the stuff well with pure water, spread it out, or hang it on a pole, and then raise the hair with this instrument; and fetch out the hair by rubbing it several ways from bottom to top, then from top to bottom, both with and against the hair: first with a dead thistle; or one that has been used before, and afterwards with a live thistle, or one that is entirely new; first with gentle strokes, and then brisker; always taking care not to make the stuff swag, and to give it a nap, without weakening the substance, by adorning the outside.

This work renders the stuff warmer, and more beautiful: but then it must undergo the sheerer's scissars; who corrects the inequality of the hairs raised by the tease, and returns it to the carder. He cards it again very carefully, and remits it, for a second inspection, to the sheerer; who now gives it at first a rough sheering, and then finishes it both inside and outside in the exactest manner, according to his art.

As the cloth cannot be supposed to pass through so many, and some of them dangerous operations, without being subject to several accidents from the tease, &c. it is, when perfectly dry, sent to the fine-drawer to mend the holes, and to strengthen the weak parts, so as the most curious eye cannot discover them: and then committed to the tenter, which is a long frame of wood with rows of hooks quite round it, and of a width and length of the longest and widest piece of cloth. This frame stands upright, and is so contrived, that the parts of it are moveable, and can be pulled backwards and forwards at pleasure. The use of this is to get out all the creases which the stuff has contracted in the fulling-trough, to keep it on the square, and to bring it, without violence, to its proper size: and, finally, to put it in a condition, either to be better brushed and more glossy, or to be folded in square folds, amongst honest dealers. Whereas a too violent stretching upon the tenter undoes all the fulling-work, and looses and weakens the cloth; leaving it swaggy, limber, and without substance: so that the legislature has been obliged to interpose their authority, and declare every piece of stuff forfeited, which has been lengthened on the tenter, more than half an ell in twenty; or stretched above a nail in width more than it was before. This fraud is detected by wetting a piece of cloth, when taken off the tenters, which will bring it immediately to its natural size.

When the cloth has continued its proper time on the tenter it is then brushed again, and always in the same direction, that the nap may lie all the same way. And the gloss and uniform inclination of the nap is accomplished principally by the means of a tool, called a jack, made of a deal board. This jack is laid over with mastic, rosin, powder of free-stone, and sifted filings, on the side that touches the stuff; which composition attracts and clears the stuff or cloth of every little straw, hair, and parings of the sheers, that happen to remain unobserved after the former process.

But to finish its lustre, the cloth must now be sent to the hot-presser, who folds the cloth or stuff in square folds; and sometimes sprinkles each fold with gum-water; and always interleaves each fold with paste-board, or very thick cartridge paper; covering the last fold with a square board, to secure the goods from the press, under which they lie for some time, till the heat has gra-

dually exhausted all the superfluous moisture, and all the hairs which point upwards are deprived of their springiness: otherwise, the first drop of rain which should fall upon the stuff, would, when it was dried away, restore to the hairs it wetted some kind of elasticity, and make that seem a stain, which is really nothing but a reflection of light different from that of the hairs which are round about it, and have not been wetted. And to prevent this mischief, they endeavour to make the press touch every-where alike: they repeat the interleaving, and sometimes, in fine cloths, supply the first leaves with others finer and sleeker; and, at some distance from each other, they add plates of wood or brass made very hot.

This work used formerly to be performed by rolling the stuffs and cloths round the cylinders of a calender, and making them pass, by the help of a turning beam, between an immoveable table of marble or hard wood, and another table very well polished, or covered with a large sheet of copper, backwards and forwards on the rollers, with a weight of 18 or 20,000 pounds weight.

Nor would we have it imagined that all this pains and charge, to give the woollen manufactures a gloss, are intended only with a view to give them an useless lustre, or to impose on the chapman by a brilliancy, which will soon fly off; but to give them a permanent beauty, and to add to them a real value: for experience teacheth that a cloth, which has not gone through these operations, never wears so well, nor gives so much satisfaction to the purchaser; it has the appearance of a very hair-cloth, without any equality in its grain, or exactness in its colour. The unequal tension of the two threads, which mutually cross each other, and the accidental diversity of stiffness and suppleness, which may happen to every part of the stuff, and even to each little fibril, necessarily dispose the whole piece to crack and pucker up: and this would be unavoidable, especially to slight stuffs, without the ingenious precautions of the dressers and pressers.

The stuffs and serges, whether those which, being very sleek, do not go to the fulling-mill; or those, which have been only beaten with water: or, lastly, such as have been beaten dry, as well as wet, in order for napping, should all be rinsed and exposed to the air. They are taken off the poles to give them the last finishing; the principal design of which is, as observed before, to destroy entirely any remaining springiness or starting, which may interrupt the equality of the texture; to incline all the hairs on one side of the piece in the same direction, that a right side may be formed; and to produce a kind of harmony through the whole piece, by rectifying all disorderly tension of the fibres within the stuff, and by the uniformity of its reflections of the light from without. This is performed in very thin stuffs by stretching them in a proper manner, each separately on a little roll, and laying all the rolls together in a large square copper kettle, on a board full of holes, which is raised to some distance from the bottom of the kettle under this board; in the kettle, is a quantity of water, which being heated, and the kettle close covered, the steam that rises is necessarily reflected by the cover, and returned back from all sides upon the stuffs, and getting into them by little and little, it supple all the hairs that have too much stiffness and elasticity. The press will do the rest.

But all fulled stuffs are sprinkled over the wrong side, first with gum-water, and, after extension on a large roller, to get out all the creases and inequalities, they are rolled off slowly upon a bar of polished iron, which supports the piece in that state over a large chafing-dish, capable, by its heat, to put the least fibre in motion; and from thence it is carried upon another roller, which draws it even by the help of a wheel or engine for that purpose. And thus the stuff is returned from one to another, at the discretion of the workmen: and this is called dressing or calendering.

In order to set this useful mechanic invention in a true light, we shall add here the most usual terms used therein, ranged in the same order as the various operations are performed.

The wool is washed; either in heaps, in standing water; or in the coyridle, in running water; or in tubs full of river water.

To prepare the bath or fuds, is to let the wool soak in water, until it has thickened the water in the tub, by discharging its greasiness and salt in it. Thence it is, that insects seek clean wool, and will not touch that which retains its natural moisture.

Wool in the greafe, is that which still preserves its natural greasiness. This is better for keeping, because the moth will not get into it.

A washing of wool, is a heap of wool, taken out of the tub, and set to drain in the air.

To wash the wool alive, is to wash it on the sheep's back before shearing.

The shears are scissars made of one piece of steel, which forms the bow and two blades. The bow is a semicircle, from whence the two blades stretch forwards. These are pressed close to each other, and cut the wool under the workman's fingers, and then fly back by the spring of the bow.

A tod of wool is what is cut off the skin of the sheep, beginning at the legs and ending at the head.

A fleece is the tod gathered up into a packet. Out of trade, a fleece sometimes signifies a sheep-skin with the wool on.

The pushes are wool finer than the rest, which shoot out by little tufts in different places. They are plucked off the sheep before shearing. In the province of Berry this last name is given to the wool taken off the thighs.

The breechings are those which are so hard and clotted, that they are of the consistence of felt. They are also called clottings, because the beast, especially when sick, dirt, and clots them by lying much on one side.

Pelled wool is that which comes off from scabby sheep.

Sprazely or crudley wool is the young hungry wool which shoots out before the old is shorn.

Locks or breechings are long white hairs, as stiff as badger's hair.

All these sorts of wool are bad or rejected. Yet it cannot be said that they ought to be thrown away as useless. They are used in very coarse works, such as ordinary rugs.

Clipping is cutting off the coarse ends of the wool, before it is washed. Those ends are called locks.

The fleece wool is that which hath been shorn off the sheep while alive.

The lambs wool is the wool cut off lambs.

The glovers wool is the wool, which the leather-dresser takes off the skin, after the sheep is killed.

The fell wool is the wool stripped off sheep which died of some distemper. The use of this sort is prohibited.

In sorting Segovia wool, it is distinguished into first, second, and third. The same order is observed in sorting Spanish wool.

As to other sorts of wool, the only distinction that is made, is into the high wool, which is the longest, and is generally reserved for combing; and the low wool, which is usually carded. However the long wool, when it is to make cloth, is also carded, because it does better so than when combed.

Fine wool unscoured, is only fit for the market, and not for working. In order to work it, in some cases they begin by washing and combing it; in others by getting out the greafe by boiling, in order to wash and comb it afterwards; and there are other cases still, in which it is first dyed, then carried to the river, and thence to the comber.

The scouring boiler, or copper, has a cross bar in it, to support the wool taken out of the water. There are also poles to stir the wool, pestles to pound or beat it, hooks to draw it out, baskets to hold and carry it to the river, where the cleaning of it is finished.

Common wool, which has been washed on the sheep's back, ought, before working, to be carefully examined, picked off the locks or clipped, and cleaned of all refuse,

In some manufactories wool is wrought white, in others it is dyed before working.

For dyeing wool the same utensils are requisite as for scouring.

The ingredients are the preparatory and colouring materials.

Setting the copper, is to put the necessary ingredients into it.

Handling the wool is to open it, by stirring it with the poles, in order to make every part of it take the colour equally.

Increasing the boiling is to enlarge the fire.

Cooling the wool is to spread it out in the air.

If the wool has been only grounded or galled; that is, if it has only had its first dip, or the first tincture of galls, copperas, or other ingredients, whether preparatory or colouring; then it must be brought in from the airing to the copper, to be there revived by a second dip, which brightens the dye, or to be lowered by a new mixture, which either diminishes its lustre, or gives it another teint; or in fine to give it a deeper cast of the same colour.

To beat the wool, whether dyed or white, is to spread it on a hurdle, and to open its texture by whipping it with switches, in order to make it fit for combing, or carding, and spinning.

For combing wool they use

A little furnace, which serves to warm the combs.

A vice and hook to fix the combs.

A pair of combs, which are two little boards, almost square, stuck with teeth of iron wire, some a little longer than others.

Each comb has its handle.

A hammer, to put in and take out these teeth.

A brass hollow tube, to mend them when out of order.

A file, to point them when blunt.

A windlass, to twist the wool soaked in soaped water,

before it be put on the comb.

A tub, in which the soap is dissolved.

To comb in water, is to comb the wool that has been sprinkled with oil, in order to wash it afterwards.

A certain quantity of wool is given by weight to the workman.

A beating, is a parcel of wool beaten on the hurdle.

A sliver is a proper quantity of wool put into the teeth of the comb.

To discharge it, is to take out the sliver, after having moved the right comb backwards and forwards on the left, and the left on the right.

The carding is the quantity of wool that sticks to each comb, and is sufficiently combed after a certain number of movements of one comb on the other. There are always two cardings, as well as two combs.

A distaff is two cardings joined together, which make up a sufficient quantity for the distaff.

The short wool, which cannot be wrought together by combing, is not lost. It goes to the card.

To brimstone the wool, is to suspend the several skeins over the brimstone room.

The brimstone stove is a little stove well closed and cemented at top, to whiten the wool by the fumes of brimstone burning in a pan.

When dyed wool is combed, they begin by mixing it according to the taste and skill of the master-worker.

The different colours are effaced by the judgment in mixing them, whereby there results a new colour.

The comber follows a certain rule in the quantity of each colour he takes for each combing: on which depends the uniformity of the colour required.

Carded wool is broke in a different manner from combed wool. It passes through two tools called cards, which are two little quadrangular pieces of board, three or four times as broad as tall, with a handle to each, and thick set with small crooked wires. The cards are changed, beginning by the widest, and ending with the closest, in order to break the wool, and mix the colours the better.

Spinning is of two sorts.

Twisted thread is spun by the spindle or little reel, from combed wool, and serves for the chain or warp, which

which is the ground of little stuffs. The name of chain, or warp, is also given to the threads running lengthwise in a piece of cloth, and which make the ground of it.

The slack spun is made by the great wheel from carded wool, and is called the wool, or shute. The wool crosses the threads of the warp, and may be called shute with regard to a stuff that has a pile.

The thread of the work in cloths, is generally called back-thrown, because being made from carded wool as well as the woof, it is likewise spun by the great wheel, but with the circumstance of crossing the wheel-string; which has a double good effect, viz. to make a thread somewhat better twisted and stronger, and to give it a different twist from that of the woof; whereby they thicken better in the fulling mill.

Stuffs may be divided into three sorts, tammy, serge, and cloth.

Tammy or stuffs of two tammies, are made of thread of warp upon thread of warp, that is, the warp is of twisted thread, and the woof of the same, both made from combed wool.

Serge is made of slack spun, or carded wool, on a warp of tammy, or combed wool.

Cloth is made of two soft threads, that is, both the warp and woof are of thread spun from carded wool, and very little twisted, in order to make a more substantial and woolly stuff.

These three fundamental sorts are subdivided into a vast number of others, according to certain qualities added to them, and different ways of working.

To weave, is to work at the loom, or to make stuff.

One weaver is sufficient for making tammy and serge; because as these little stuffs are not wide, the same workman can throw his shuttle with his right hand between the threads of the warp, and receive it with his left, in order to throw it the contrary way. But cloths and blankets, being very wide, are wrought by two weavers, one of whom throws the shuttle, the other receives and throws it back; and they go on thus alternately with as much regularity, as if the work was done by the two hands of the same man.

The loom is composed of several parts, whereof the chief are the loom-posts and cross-bars.

The three rolls or rollers, viz. the little one, the knee-roll, and the cane-roll.

The warp is at first fastened at one end of the loom on the least of these rollers, and at the other end is rolled on the second cylinder, which is thicker, and is called the cane-roll: according as the warp is filled with woof, the stuff is to be rolled under the loom on the knee-roll; and at the same time the same length of the thread of the warp is unrolled off the cane-roll, as that of the stuff rolled on the knee-roll.

The batten is a large moveable frame suspended on two pins at the top of the loom, to move freely backwards and forwards, under the workman's hand, who, after every throw of the shuttle or thread of the woof, strikes in this thread more or less with the batten and reed.

The reed or comb is made of two rods, with a long row of teeth of reeds, or brass wire. It is placed at the lower part of the batten. Every thread of the warp passes singly between two teeth of the reed: that so the batten may move without breaking the threads, and strike in the woof equally, without leaving any part of it irregular.

The lams are behind the reed. Each lam is composed of two virgees or laths, whose length should be the width of the stuff, and of little strings stretched from one virgee to the other, which are called leishes. In the middle of each leish there is a loop or little ring of thread, horn, or glass, to receive one of the threads of the warp. Those threads of the warp, which pass through the loops of one lam, pass between the leishes or threads of the other lam; and those which pass through the loops of the second lam, pass freely between the threads of the first; so as to be able to descend, while the first ascends: and thus these two lams being near their ends fastened to a common cord passed round a pulley at top, and at bottom

to another cord which supports a treddle, lying under the workman's feet; if he lowers the fore lam with his left foot, the other lam must rise up. The reverse happens upon a contrary motion. If there are a greater number of lams to vary or figure the stuff, certain parcels of threads are thus raised and lowered at a time, whereby divers openings are made to receive the throw of the shuttle. As often as the foot is changed, and the warp receives a new throw of the woof, the batten closes it more or less according to the quality of the stuff. When the increase of the stuff hinders the play of the batten, there is as much of the warp rolled off the cane-roll, as of the stuff rolled on the lower great cylinder. Concerning the manner of guiding the threads of the warp through the rings of the jack on the warping mill; of managing the separation of the threads of the portee; of uniting several portees in one chain; and of making one entire warp of them all; of brushing or moistening it with size, to make the threads glide easier in working; of mounting it on the loom, by fastening it in a groove of the little roller; of passing the threads in good order through the teeth of the reed, and then dividing the same threads, and making some of them go through the loops of one lam, and between the leishes of the next; and others between the leishes of the first, and through the loops of the second; of fixing and maintaining the divisions of the threads, by the insertions of several rods which prevent their mixing; of facilitating, in fine, the unwinding and play of the warp and woof by the usual precautions and proper tools; these operations are easily comprehended at first sight: but their number is so great, that if the workmen did not use great dispatch, by every one constantly plying to his own part; sheep's wool either would never be converted into cloathing, or would bear too high a price for the common people. Let us not remain unacquainted with what shews the greatest industry, after the play of the lams.

The shuttle is a piece of hard wood, that runs tapering to a point at both ends, and has a cavity in the middle, called the box or chamber, for receiving the quills.

The quill is a small pipe of reed, on which a proper quantity of the thread of the woof has been wound, and which plays on the shuttle pin.

The shuttle pin is an iron wire, which runs through the quill, and with it is set in the chamber of the shuttle. It is put in, secured, and taken out, by the different action of a spring at the end of the chamber, where the shuttle pin is placed.

As the shuttle runs through the warp, the thread of the woof, which slips through a hole or eye in the side of the shuttle, and has been fastened to the lizier, must run off the quill, which runs round as the shuttle goes on. When this quill is emptied, another is put in its place; and the ends of the thread of the two quills are laid close to one another without knotting; only taking care to manage the throw of the shuttle, so as to be sure of keeping both these ends of the woof together.

The heads of the piece are some few inches of the stuff, made with a different sort of woof from the rest. The names of the workmen and place are wrought in it: and afterwards the lead-seals are put to it, which are a testimony of its being examined and found to be of good materials, and of the breadth and quality required by the laws for the respective sorts.

The temple is composed of two flat notched rulers, secured one over another by a sliding ring, and having pins points at their ends. The workman fastens the two ends, full of points or spikes, to the two liziers, or lifts, which are the outer threads of the width of the stuff; and, by bringing the virgers or laths more or less forward, he keeps the stuff constantly of an equal breadth. If he did not take care to temple his stuff, the woof would shrink unequally, and bring the threads of the warp nearer together in some places, and in others farther asunder. But by removing his temple from time to time, to keep it near the last throws of the woof, he strikes the woof in upon a square, and so as to make it receive the stroke of the batten equally in every part.

The

The workman continues to throw the shuttle, to temple, and to wind off alternately. When he is come to the end of the piece, he takes another sort of thread for the woof, as he had done at beginning it, and makes a stripe of a different colour, for the names and seals, as above. These two ends are called the head and the sag-end.

To steam a little stuff, as is done at Amiens, Rheims, and La Mans, is to render it supple, by exposing it to the steam of boiling water in a square kettle or copper, where it is laid, still on its roller, with other pieces. This operation disposes it for dressing well.

The fullery is a water-mill for working great mallets on stuffs, either to clean them, or thicken them to the consistence of felt. See the article *FULLING*.

The stocks, or fuller's pots, are hollow vessels to hold the stuffs, which are continually turned under the strokes of the mallets.

The levers, or prominent bars, are the ends of pieces of timber, that run through the axle-tree or arbor of the wheel, and which, as they pass, catch the heads of the mallets, raise them up, and let them fall as they go off.

To earth the stuff, is to rub it with fuller's earth.

To beat it in the earth, is to full the stuff with the earth on it, letting a water-cock run on it at the same time.

To scour cloth, is to full it after soaping it with black soap, which carries off all spots.

To clean-stuff, is to full it with a great deal of water, to carry off any remains of dirt, and to rinse it.

To beat it dry, is to full it without water, till it has acquired the utmost thickness it is capable of, and beyond which it runs into a pap.

When stuffs come from the fulling-mill, they are aired, that is, hung out.

The pieces brought from off the poles or tenters, ought to be made up, that is, properly folded on a table; then gummed at every fold, by sprinkling the backside with a solution of gum arabic in water.

To stretch the stuff, is to pass it from one roller on another, keeping it constantly of the same breadth, over a brasier, by means of an iron bar, on which it slides; whereby the heat penetrates, and breaks its stiffness. And, by thus passing several times from one roller on another, it is rendered pliant in every part alike.

There are some stuffs that are unrolled and rolled without fire. But it is always allowed to such as are to be dressed very well.

The effects of this stretching are, first, to smooth or take out the bad folds; secondly, to gum the whole piece equally by the fire's spreading the moisture everywhere, which evaporates, and leaves the gum behind. Thirdly, to stretch the whole in an uniform manner: which is of vast consequence in the wear of stuffs.

They are folded near a good fire.

They are leafed, by putting a leaf of pasteboard hot, between every two folds.

They are put between two thick boards of box, which take in the whole pile of folds.

They are left ten or twelve hours in a strong press: and this is repeated three or four times.

They are visited for the last time, and after drawing out the two ends, called the head and sag-end, the lead-seals, tickets, and other marks are put on which denote the quality, breadth, length, dye, and other things prescribed by the laws: then they are put into the press again, and stitched, by securing the folds loosely with threads run through the liziers.

There are some other practices peculiar to different manufactories; but they all tend to the same end.

Cloth is not stretched on the rollers; but, after having been full'd, teazled, tenter'd, or hung on the rack, shorn twice, cottoned, and the pile laid smooth one way, it is gummed or folded on leaves, put to the press, the leaves are changed, and, instead of thick coarse pasteboards, others thinner and smoother, called cards, are put between the folds: it returns to the press, or else to the calender, which gives it its last gloss. *Spectacle de la Nature, Tome VI.*

Explanation of the Plates representing the most material operations of the Woollen-Manufacture.

Plate CXLI. Washing the wool.

Fig. 1. A, the tub in which the wool is washed.

B, the workman washing the wool.

C, the wool in the tub.

Fig. 1. N^o. 2, D, part of a river in which the wool is rinsed, and cleansed.

E, a coyridle containing the wool to be rinsed.

F, the workman performing the operation.

G, a portable board, resting on piles, on which the workman is supported.

Fig. 2. two workmen employed in stirring the wool.

A, the tub.

B, B, the staves with which the workmen stir the wool.

Fig. 3. Horses for drying the wool after it is cleansed.

A, A, &c. B, B, &c. poles charged with washed wool.

Plate CXLII. Picking and beating the wool.

Fig. 4. A workman employed in picking the wool.

A, the hurdle, on which the wool is placed.

B, the wool.

C, the picker.

Fig. 5. Two men employed in beating the wool up on a hurdle.

A, the hurdle on which the wool is placed.

B, B, the workmen beating it.

Fig. 6. The cards, &c. for carding the wool.

A, B, the horse for supporting one of the cards.

e, the card fixed on the horse.

D, the other card, seen on its upper side.

f, a box for holding the wool.

Fig. 7. b, the great cards.

Plate CXLIII.

Fig. 8. c, c, the little cards.

Spinning the wool.

Fig. 9. N^o. 1, and 2. The great spinning-wheel.

A, the form or support of the wheel.

b, b, the supporters of the broche.

C, the large wheel.

D, the arbor of the large wheel.

e, the reed, on which the thread is wound in a conical form.

f, the head of the reed on which the thread is wound.

g, the arbor on which the reed is fastened.

h, the pulley, round which the string of the large wheel passes.

H, the post which supports the large wheel.

Measuring of the thread.

Fig. 10. and 11, the reel for winding and measuring the thread.

A, the form of the reel.

b, b, b, posts or supports of the reel.

c, c, c, c, arms of the measuring reel.

d, d, arbor.

e, pinion of the arbor.

D, the toothed wheel in which the pinion of the arbor moves.

F, the wheel carried by the pinion of the arbor.

G, the hammer.

h, pinion fixed on the arbor of the wheel F.

i, thread wound upon the wheel F.

k, a weight, keeping the thread tight.

l, a small anvil, on which the hammer strikes at proper intervals.

Forming the chains.

Fig. 12. A workman forming a chain.

A, the tub.

B, B, the chain.

C, the paste.

D, the workman.

Small rectangular stamp or seal impression in the upper left corner, containing illegible characters.

Small rectangular stamp or seal impression in the upper center, containing illegible characters.

Large, faint rectangular stamp or seal impression in the upper right, containing illegible characters.

Large, faint rectangular stamp or seal impression in the center of the page, containing illegible characters.

Small rectangular stamp or seal impression in the lower left, containing illegible characters.

f, the block.

g, the pulley.

WORD, in language, an articulate sound designed to represent some idea. See SOUND, VOICE, SIGN, IDEA, &c.

WORD, or *Watch Word*, in an army or garrison, is some peculiar word or sentence, by which the soldiers know and distinguish one another in the night, &c. and by which spies and designing persons are discovered. It is used also to prevent surprizes. The word is given out in an army every night to the lieutenant, or major-general of the day, who gives it to the majors of the brigades, and they to the adjutants; who give it first to the field-officers, and afterwards to a serjeant of each company, who carry it to the subalterns. In garrisons it is given after the gate is shut to the town-major, who gives it to the adjutants, and they to the serjeants.

WORK, in the manege.—To work a horse, is to exercise him at pace, trot, or gallop, and ride him at the manege. To work a horse upon volts, or head and haunches in or between two heels, is to passage him, or make him go side-ways upon two parallel lines.

WORKS, *Opera*, in fortification, the several lines, trenches, ditches, &c. made round a place or army, or the like, to fortify and defend it.

WORLD, *Mundus*, the assemblage of parts which compose the universe. See the article UNIVERSE.

WORMS, in the Linnæan system of nature, a class of insects of the order of the apteria, and of the class of the anarthra.

The distinguishing character of this class is; that they have the muscles of their body affixed to a solid basis. The several species of worms are very numerous; as the chætia, or the hair-worm, called also the guinea worm; the ascaris, the lumbricus or the earth worm; and sea-worm; the tænia, or tape-worm; the sicyania or gourd worm; the iulus or gally-worm, &c.

WORMS, *Lumbrici*, or *Vermes*, in medicine, certain living animals of various figures, structures, and bulks, which are formed in the intestines, from the seeds of some insects taken in with the aliments.

These animals are nourished in the body by a certain putrid juice, and greatly weaken and injure the body, and its several functions.

The belly is frequently the seat of worms; and they are of three sorts, the round smooth sort, the ascarides, and the flat or jointed worms; children are chiefly troubled with the first and second; and adults with the third and worst sort. These have been all treated of by many medical writers: but the learned Daniel Le Clerc has given the most accurate description of the flat worm, illustrated with figures. And as he has refuted the erroneous opinions of some physicians concerning this creature, which seems to be an animal of a singular nature; I have borrowed from him the following remarks. First, it manifestly appears, that this is not a single worm but a chain of many lesser worms, of that kind which are called cucurbitine, linked together in a continued series. Secondly, these latter are sometimes found, of a finger's breadth, lying single and separate in the intestines, and are so discharged by the anus. Lastly, the whole worm formed of a concatenation of these has but one head, which is pretty sharp-pointed, sometimes resembling a beak; which it fixes into the coats of the intestines, and sticking there very fast, sucks the chyle for its nourishment.

To these observations of Le Clerc I shall add, says the learned Dr. Mead, some few from my own practice; for I have seen and cured this disease more than once. And, indeed, it is a truth equally strange and disagreeable, that though the medicines have destroyed, and brought away, several of the small worms, which were the component parts of the great one; yet, others daily breed in the body, and join themselves to the rest, in order to repair the breach, until the head is expelled; and then at length the whole animal is discharged with it by the anus, and is frequently several feet long. But it is not at all surprising that the sharp beak above mentioned should cause pain; and that the person who entertains this devouring guest, and is under a necessity of supplying its daily food, should waste in his flesh, and even run into a decay.

Wherefore, these pernicious broods of worms are to be destroyed by all possible means; and this is easily done with regard to the smooth and round sort, and the ascariides. Quick-silver in every form is destructive of them; and, therefore, it will be very proper to order a purge of rhubarb with a small portion of mercurius dulcis, which is to be repeated at due intervals; and, on the intermediate days, to give æthiops mineral morning and evening. Moreover, it will be of service to drink spring water, in which quicksilver has been boiled; and even sea-water alone. In fine, oil injected by the anus does good.

But the flat worm requires a peculiar treatment; and after many years experience, I recommend the following medicine as very efficacious in this case.

Take filings of tin, and red coral, of each an equal quantity; pound them together into a very fine powder; of which one dram, made into a bolus, with conserve of the tops of sea-worm-wood, is to be taken twice a day.

In fine, the same medicines, which have destroyed and cleared the bowels of these intestine enemies, are to be repeated from time to time to prevent their return.

Worm-Seed, a hot, bitter, drying kind of seed, often given to destroy worms in the human body.

This seed is small, of a brownish colour, an oblong figure, a bitter taste, and a strong smell.—It must be chosen new, greenish, of a sharp, bitter, aromatic taste, not a little disagreeable.

The place where it is produced is Persia, about the frontiers of Muscovy. It is brought to us from Aleppo, &c. Naturalists are not agreed about the plant that produces it. J. Bauhine has a large dissertation on the subject. Some will have it the species of absinthium, or worm-wood, called *fontanicum*, or *marinum absinthium*; others will have it the *tanacetum*, others the *abrotanum*.

M. Tournefort gives us the following account of this notable drug, in the second volume of his Travels. The *sementine*, or worm-powder, is not gathered like our seeds. The plant grows in the meadows, and must be let ripen; and the mischief is, that as it grows near to maturity, the wind scatters a good part of it among the grass, where it is lost; and this it makes it so dear.

As they dare not touch it with the hand, for fear of making it spoil the sooner; when they would gather what is left, in the ear, they have recourse to this expedient. They take two hand-baskets, and, walking along the meadows, sweep the baskets, right to left, the other from left to right, as if they were mowing; by this means the seed is shook out into the baskets.

WORMWOOD, *Absinthium*, in botany. See the article **ABSINTHIUM**.

WORSHIP of God, the offering up of adoration, prayer, praise, thanksgiving and confession to God, as our creator, benefactor, lawgiver and judge.

WORSTED, a kind of woollen thread, which, in the spinning, is twisted harder than ordinary. It is chiefly used either wove or knit into stockings, caps, gloves, or the like.

WOULDING, a sea-term for the winding of ropes round a mast or yard of a ship, that has been strengthened by a piece of timber nailed to it.

WOUND, *Vulnus*, in medicine and surgery, is frequently defined to be a violent solution of the continuity of the soft external parts of the body, made by some instrument. Others take a greater latitude in defining it, and call every external hurt of the body, by what cause soever produced, a wound. On the other hand, some are of opinion that unless the injured parts of the body are divided by some sharp instrument, as by a sword or knife, it is by no means to be called a wound; but notwithstanding, it is certain that those wounds which are produced by blunt instruments may properly enough be called wounds, whence Heister distinguishes two different kinds of wounds, the one made by acute, the other by blunt instruments.

Wounds are generally inflicted upon the softer parts of the human body, such as the skin, fat, muscular flesh, ligaments, blood-vessels, and nerves, and parts that are composed of these, as the viscera and intestines; yet the

more solid parts of the body are by no means to be here excluded, as the bones, whence the parts that are subject to those injuries, will afford two distinctions of wounds; one, wounds of the softer parts, the other, wounds of the bones.

As causes of wounds, all instruments of what kind soever, whether blunt or sharp, may properly be reckoned, provided they are of such a nature, that upon the violent external application of them, they are capable of producing a solution of continuity in the parts of the body upon which they are inflicted; for a solution of the external parts by internal cause is not called a wound, but rather an abscess, or ulcer; so when the harder parts of the body, as the bones, are broken by a fall, or a violent blow received from a blunt instrument, it is called a fracture.

The effects which are produced by wounds, besides the division of the softer parts, are generally profusions of blood, though they are sometimes attended with much greater mischiefs than these; for it can scarcely happen, but that the divided parts must, in some measure, if not totally, lose their natural functions, according to the different uses for which the part is intended, and according to the different degrees of injury that it receives.

The greater number of uses a part is intended for by nature, the worse will be the consequences of a wound upon that part; this principle is so extensive, that it is the constant guide in forming a prognostic, whether a wound will prove mortal or not. He, therefore, who is best skilled in anatomy, that is, best instructed in the situation of the parts, and their uses, will be enabled to form the most accurate judgment of the consequence that will necessarily attend a wound upon any particular part.

What has been said of the different situations and causes of wounds, sufficiently demonstrates, that there are many different kinds of wounds, some brought on by a puncture, some by a stab, and some again by a blow; some are curable, others incurable; some are made with sharp instruments, others with blunt ones: with regard to their figure, some form a right line, others are curved, transverse, or oblique: with respect to their situation, some are placed in the head, others in the neck, thorax or abdomen; and of these, some are internal, others external. Variety of different wounds arise from the great diversity of condition that wounds are left in; for in some wounds, the inflicting instrument, or part of it, remains; for instance, a leaden bullet, a piece of glass, or of a granade; the points of arrows or swords: but in some wounds, nothing of this kind is left: sometimes fractures of the bones accompany wounds, which is generally the case in gun-shot wounds: some wounds are also attended with poison, as those which are made with poisoned arrows; under this head may be ranked the bites of animals, but more particularly of mad or venomous animals. Some are of opinion, that wounds which are made with copper, or silver instruments, should be reckoned in this class, the poison of which, if there is any, is owing to the vitriol that is mixed with these metals.

In slight wounds, where no considerable artery, nerve, or tendon is concerned, the following appearances are usually remarkable; at first sight, the wound appears as a red line drawn upon the part; but upon being dilated, the blood instantly gushes out in greater or smaller quantities, according to the size and number of the blood-vessels that are injured.

The hæmorrhage, after a short continuance, stops of its own accord, and the blood concreting in the wound, forms a crust; the lips of the wound now begin to look red, and swell, and are attended with some degree of pain and inflammation; if it is a large wound, a fever, that is to say, an universal heat and quickness of pulse, almost always ensue upon the third or fourth day; sooner or later, a white glutinous humour appears, not unlike oil, and this is known by the name of pus, or matter; upon appearance of matter, the redness, tumour, pain, inflammation, and fever, disappear entirely, or at least are abated; and these are the signs of a wound inclining to heal; for under the matter new flesh springs up from the wounded vessels,

which having by degrees filled the wound, dries upon its upper part, and forms a cicatrix.

In dangerous wounds, that is, where any considerable blood-vessel is wounded or divided, there generally ensues so violent a hæmorrhage, that the wounded person is in an instant sensible of great loss of spirits, and weakness, and faints away: and when the larger arteries are wounded, whether they are internal or external, he dies upon the spot; although somewhat less danger is apprehended from wounds that are inflicted upon the vessels, which are situated upon the external parts of the body, some few excepted, because they will admit of the ligature, and other means of restraining the violence of the hæmorrhage.

There is nothing will give a truer light into the nature and consequence of a deep wound, than a due consideration of what natural actions of the body are impeded thereby. For instance, in wounds of the breast, when the patient draws his breath with shortness and difficulty, and is at the same time attended with a hæmoptysis and hiccough, it may be rationally conjectured, that the lungs or the diaphragm are wounded; so in wounds of the abdomen, when chyle is voided, it is a plain indication that the stomach, small guts, or lacteals are wounded: when excrements pass by the wound, the great guts are wounded.

Bilious blood likewise shews the liver or gall-bladder to be divided: if urine passes by the wound, the urinary bladder, or else the ureters, are wounded; and bloody urine denotes a blow on the kidneys, or a wound of the bladder; but when there are large profusions of blood this way, it is a sign that some of the larger blood-vessels are wounded: vomiting of blood declares the stomach to be the injured organ: violent pains attended with convulsive twitches, shew that a nerve is wounded, or else that some foreign substance is left in the wound. Whenever the senses are disordered after a wound received on the head, a concussion of the brain is much to be feared. Difficulty of breathing, pains in the breast, and hiccoughing, are symptoms of a wound in the diaphragm.

It is of bad consequence for a wound to be attended with a large tumour; but it is of the last consequence if it is attended with no degree of tumour at all: the first is an indication of great inflammation, the last of mortification; some degree of tumour is always therefore best in wounds.

In order to enquire what wounds admit of a cure and what are incurable, Heister divides wounds into three sorts. 1. Some wounds are absolutely of themselves mortal. 2. Others are in their own nature mortal, if not relieved by timely assistance. And, 3. Others become mortal by accident or imprudent treatment, though they were otherwise curable.

1. We properly style those wounds mortal which are not to be remedied by all the art and industry of man. Thus, wounds are of this kind which are attended with so violent an hæmorrhage as to produce instant death: of this sort are reckoned wounds that penetrate the cavities of the heart, and all those wounds of the viscera where the large blood-vessels are opened; such are large wounds of the lungs, liver, spleen, kidneys, stomach, intestines, mesentery, pancreas, uterus; of the aorta, of the iliac, cœliac, renal, mesenteric, and carotid arteries: especially if they are wounded near their origin: of the subclavian also, or vertebral; of the vena cava, iliac vein, the internal jugular vertebral, renal, mesenteric; of the vena porta, and of the larger veins that lie deep in the body, because their situation will not admit of proper applications to restrain the flux of blood. Heister therefore reckons, very justly, these among the wounds that are absolutely incurable, since they are not remediable either by astringents, ligature, or fire.

Those wounds also are not less mortal than the former, which obstruct, or entirely cut off the passage of the animal spirits to the heart; such are wounds of the cerebellum, of the medulla oblongata, and some violent strokes of the brain itself.

There is reason to apprehend very great danger, when the small veins or arteries which are contained in the cranium, are injured; for the blood flowing from them into the internal sinuses of the brain, either produces too

great a pressure upon those very tender parts of the brain, and so obstructs the course of the blood and spirits; or else, being corrupted, it putrifies the brain itself, if it cannot be evacuated by the assistance of the trepan; which is the case when this accident happens at the lower part of the cranium, or in the sinuses of the brain; nor is there less danger where the nerves which tend to the heart are wounded, or entirely divided; for, after this, it is impossible for the heart to continue its motion.

To this class are to be referred also all wounds which entirely deprive the animal of the faculty of breathing: there is therefore great danger where the *aspera arteria* is entirely divided; for where it is only divided in part, it may be healed again by the assistance of an expert surgeon: to this place also belong violent shocks of the bronchia, mediastinum, and diaphragm, especially the tendinous parts of it.

Those wounds also which interrupt the course of the chyle to the heart, are no less incurable than the former; such are wounds of the stomach, intestines, receptacle of the chyle, thoracic duct, and larger lacteals; to which may be also added wounds of the œsophagus, if they are large; though death is not so sudden an attendant on these wounds; but, for want of nourishment, the persons afflicted by them are weakened by degrees, and at length die consumptive.

In this account those wounds also are not to be omitted, which are inflicted upon membranous parts, that are situated in the abdomen, and contain some secreted fluid, as on the bladder, either of the bile or urine, the stomach, intestines, receptacle of the chyle, and lacteal vessels. The fluids contained in these parts, when once they are let loose into the cavity of the abdomen, cannot be properly discharged, and therefore easily corrode the internal parts of the body; and the membranes that contained them are generally so fine, that they will not admit of agglutination, especially since no medicine from without can be applied. A few indeed have recovered after slight wounds in these parts; but since the number of these instances is but few, and the cure in them has been accidental, and not performed by the surgeon's art, these may very justly be added to the list of mortal wounds.

2. Many wounds there are which though the experienced surgeon could remedy, yet prove fatal, if neglected, or left to nature: of this number are those which produce instant death, unless relieved by present assistance; such are wounds of the larger external blood-vessels, which might be remedied by ligature, by the application of astringent medicines, or the actual cautery. Of this kind are wounds of the brachial, or crural artery, unless they are too near the trunk of the body; wounds in the large arteries of the cubit, or tibia of the branches of the external carotid, or temporal artery; to these also may be added wounds of the jugular and other veins, situated upon the external parts of the body; but in these cases no help can be given, unless the surgeon be brought before there has been a vast profusion of blood.

3. Wounds are properly said to become mortal by accident, where the patient's death from them is occasioned either by the ill conduct of the patient himself, or by the neglect or ignorance of his surgeon; the wound itself being of the number of those deemed curable by the judicious practitioner. Under this head are to be reckoned, 1. Those wounds which the surgeon has neglected to cleanse sufficiently, though he had not it in his power to do it; as when some foreign body, which might easily have been extracted, is left in the wound, and produces inflammations, hæmorrhages, convulsions, and finally death itself; so in wounds of the thorax and abdomen, if the surgeon does not use his utmost diligence to evacuate the grumous blood, it will corrupt there, and by drawing the neighbouring parts into consent, will expose the patient to death: great care must also be taken that the lips of the wound do not close till the blood that is collected in the cavity of the body be all evacuated if possible, which will be easily perceived by the difficulty of breathing, and other bad symptoms going off; but if any of the larger internal vessels are wounded, then all attempts to discharge the blood are vain, for the violence of the hæmorrhage

hæmorrhage takes off the patient. 2. Wounds are also to be accounted mortal by accident, which are treated or searched in too rough a manner by the surgeon; for if wounds are handled roughly, which are full of nervous parts, or of large blood-vessels, there is great danger of bringing on hæmorrhages, convulsions, inflammations, gangrenes, and finally death itself. The case is also the same, 3. in external wounds, which are slight of themselves, but under which the patient is lost by the inflammation, which is increased and brought on by the surgeon's injudicious treatment; or, 4. when any one is taken off by the violence of the hæmorrhage from a wound of the hand or foot; for in this case, the surgeon might easily have stopped the blood by the application of proper remedies, or by ligature; or, 5. when the patient is guilty of any intemperance in eating or drinking, or of any excess of passion, of exposing himself to the cold air, or of using violent exercise. For by these means, wounds, more especially those of the head, by being liable to fresh hæmorrhages, and other dangerous accidents, frequently become mortal, notwithstanding they naturally would not prove so, and though the surgeon uses his utmost care and skill. 6. Among these are to be accounted those wounds of the head, where the patient is lost by the vast quantity of blood which is extravasated in the cavity of the cranium, and confined there; but where he might have been relieved if the trepan had been applied in time; for though wounds of this kind generally prove incurable, yet, as there is at least a possibility of saving a person in these circumstances, by the use of the trepan, this may properly be reckoned among the doubtful cases, and not deemed absolutely mortal. 7. And lastly, a bad habit of body prevents the cure of wounds, which would admit of an easy cure in healthy subjects; so we often see the slightest puncture on the hand or foot of an hydropical, consumptive, or scorbutic person, shall produce a gangrene, and prove mortal; though the surgeon spares no care nor application to prevent it.

Cure of WOUNDS.—Since a wound is a solution of the continuity of the parts of the body, the reunion of those parts seems to be the principal intention; but since wounds are of very different kinds, some slight, and others of great consequence, in proportion to this difference, so will the manner of prosecuting this intention differ.

The cure of slight wounds is generally performed with great ease, by applying a small portion of lint to the part, well saturated with spirit of wine, oil of eggs, turpentine, basilicon, the balsam of Arcæus, of Peru, &c. securing the dressings with a plaster, and renewing them once in a day or two: by this means, the lips of the wound will presently agglutinate.

Wounds which are attended with some danger, are to be treated as follows: in the first place, the wound is to be cleansed from all extravasated blood, fordes, &c. In the next place, if a bullet, the point of a sword, any part of the clothing, a piece of glass, or any other foreign body, shall remain in the wound, it is to be removed with the fingers, or with proper instruments for the occasion.

The hæmorrhage is to be stopped at the first dressing; the divided parts are to be brought as near each other as possible, and their situation is to be so maintained, that the cicatrix which is left may appear even.

The method of treating a cut, or such a wound as is made by a cutting instrument, where no part of the flesh is taken off, and the accident happens to the external parts of the body, and does not penetrate deep, after the wound is cleansed, it should be dressed with the same vulnerary balsam, and the lips of the wound should be closed, and kept in that situation. This is done after different methods, according to the difference of the wound; as,

1. It is to be done by placing the wounded part in a proper posture; that is, as soon as the wound is dressed, the part should be placed in such a situation, that the divided parts may be most likely to keep in constant contact,

2. By a proper bandage, tying up the parts so that the lips may meet, and thereby easily unite.

By a proper future, which differs according to the difference of the wound, but may be generally divided into the dry and bloody future; the dry, or as some call it, the bastard future, is the application of sticking plasters, to keep the lips of the wound united; the bloody, or true future, is performing the same thing with a needle and thread. See SUTURE.

If the wound heals by the assistance of the future, the threads or ligatures are to be cut near the knots; the lower lip of the wound is to be suspended with one hand, while the threads are gently drawn out by the other; the punctures that are left will easily heal by the application of a vulnerary water, called by the French, *P'eau d'arquebuse*; or by injecting aqua calcis, or spirit of wine, and laying on compresses dipped in the same liquors: but larger wounds are to be dressed with the balsam of Arcæus, or balsam of Capivi, and the lips kept firm together with some sticking plaster till a firm cicatrix is formed.

Where there is a loss of substance, the wound will not unite either by the help of plaster, or future, till it is filled up with new flesh. For this purpose, you will find lint dipped in oil, or spread with some vulnerary balsam, or ointment, and applied to the bottom of the wound, very serviceable, covering it with a plaster, compress and proper bandages, and this dressing is to be repeated daily.

As hot or cold air is very hurtful to wounds, so it must by all means be kept from them; for which reason, the surgeon should be careful not to remove the old dressings till the fresh ones are got ready, and to be as expeditious as possibly in applying them. After this, when a white, even, thick, matter appears in the wound, it should be dressed as you see occasion, every day, or every other day; the superfluous matter should be wiped away with a very light hand; for it is better to leave some behind, than to treat the wound roughly. These rules being observed, the flesh will spring up presently, and the wound unite; and in order to perfect the cure of the wound, an even cicatrix should, if possible, be procured.

When any uncleanness or foulness is perceived in a wound, that is, if the flesh is putrid, fungous, black or livid, it must be well cleansed before any attempt is made to heal it; for which purpose apply a digestive ointment, made with turpentine, yolk of eggs, and honey of roses; and where this is not strong enough, substitute the Egyptian ointment, or spirit of wine diluted; or if you require more strength, use red precipitate mercury. Applications of this kind are to be continued till the wound is entirely clean; after which, recourse is to be had to the methods already prescribed. If the new flesh should be luxuriant, and rise up so as to prevent the formation of an even cicatrix, it must be taken down with green vitriol, or a powder composed of burnt alum, and red precipitate mercury; at the same time making a proper pressure, with the plasters, compresses, and bandages, till the parts are even.

The patient should observe a strict regimen with regard to his diet and manner of life, as nothing forwards the cure so much as a good habit of body, which may be procured by observing a strict regularity with regard to diet, air, keeping the passions under, and indulging neither too much sleep, nor suffering too great watchfulness; and it is to be observed, that the greater tendency there is in a patient to a diseased state of body, so much the stricter course of life ought he to observe.

The bowels should by all means be kept open, especially in those who have received a wound in the head; however, it is to be observed, that strong cathartic medicines are to be avoided; but it is not only safe but adviseable to eat and drink those things that may at the same time nourish and keep the body open. To this end the patient may drink plentifully of tea or coffee, may eat stewed prunes, roasted apples: but hard meats of all kinds are forbid: where the patient is so bound up, that a diet of this kind has no effect, it will be necessary to have

have recourse to medicines, but then those must be of the mildest kind; here a gentle clyster may be given, a suppository may be used, or an ounce or two of manna, or some purging salts in warm broth may be prescribed: whenever the violence of the wound, or the ill habit of the patient require the use of internal remedies, vulnerary drinks will be found to be of the greatest consequence, in composing which, the constitution of the patient, and the nature of the complaint should be diligently consulted; for if the patient is of a phlegmatic habit of body, cold, pale, or naturally subject to tumours, then the vulnerary decoction should be composed of herbs that attenuate and divide the blood.

If the patient has a thin sharp blood, then decoctions of viscous and glutinous plants will be proper; but if he is vexed with great pain or wakefulness, then some opiates must be administered. If he should be troubled with an acidity, absorbents are proper; and when a quickness of pulse, and an extraordinary heat are perceived, they are sure signs of a symptomatical fever.

WOUNDS in Horses. The most terrible wounds these creatures are subject to, are those got in the field of battle. The farriers that attend camps, have a coarse way of curing these; but it is a very expeditious and effectual one.

If the bullet be within reach, they take it out with a pair of forceps; but if it lie too deep to be come at, they leave it behind, and dress up the wound in the same manner as if it were not there. They first drop in some varnish from the end of a feather, and when the bottom is thus wetted with it, they dip a pledget of tow in the same varnish, which they put into the wound, and then cover the whole with the following charge: take a quarter of a pound of powder of bole armenic, half a pound of linseed oil, and three eggs, shells and all; add to these, four ounces of bean flour, a quart of vinegar, and five ounces of turpentine; this is all to be mixed over the fire, and the wound covered with it.

This application is to be continued four or five days; then the tent put into the wound is to be dipped in a mixture of turpentine and hogs-lard; by this means a laudable matter will be discharged, instead of the thin sharp water that was at first. Then the cure is to be completed by dressing it with an ointment made of turpentine, first well washed, and then dissolved in yolks of eggs, and a little saffron added to it.

This is the practice in deep wounds that do not go through the part; but in cases where the bullet has gone quite through, they take a few weavers linen thrumbs, made very knotty; these they make up into a kind of link, and dipping it in varnish, they draw it through the wound, leaving the ends hanging out at each side; by means of these they move the link or skain three or four times a day, always wetting the new part that is to be drawn into the wound with fresh varnish.

They put on a charge of bole armenic, &c. as before described, on each side of the wounded part, and continue this as long as the wound discharges thin watery matter, or the sides continue swelled. After this, they dress it with the ointment of turpentine, yolks of eggs, and saffron, till it is perfectly cured.

The other methods are the dressing the wound with an ointment made of wax, turpentine, and lard, and covering it with linen rags wetted with cream, or the dressing with a mixture of yolks of eggs, honey, and saffron, and covering it with cream and balm leaves beaten together.

When the wound is so dangerous as to require the assistance of internal medicines, they give the following pills: take assa-foetida, bay-berries, and native cinnabar, of each a pound; beat up the whole into a mass with brandy, and roll it into pills of fourteen drams weight each. These are to be laid in a shady place to dry, after which they will keep a long time without any damage. The horse is to take two of these every other day, or, if necessary, every day, till he has taken eight or ten of them; and he is to stand bridled two hours before and after taking them.

When the wound seems at a stand, not appearing foul, and yet not gathering new flesh, there must be recourse had to the following powder, whose effect in bringing

new flesh is wonderful: take dragon's-blood and bole armenic, of each two ounces; mastic, olibanum, and sarcocolla, of each three drams; aloes, round birth-wort, and common iris root, of each a dram a half; make the whole into a fine powder. This is sometimes used dry, sprinkling it on the wound; but sometimes it is mixed with turpentine, sometimes with juice of wormwood, and sometimes with hony of roses, and either way does very well.

When the wound grows foul, and requires a detergent to cleanse it, the common liquor for this purpose is a phagedenic water, which they make of lime-water and sublimate in this manner: take two pounds and a half of newly made and unslacked lime, put it into a pewter vessel, and pour on it five quarts of boiling water; when the bubbling is over, let it stand to rest two or three days, stirring it often with a stick: then pour it clear off, after a due time, for the lime to settle; and filter it through some whited-brown paper, made for the lining of funnels on this occasion.

To a quart of clear lime-water thus prepared, add eight ounces of spirit of wine, and one ounce of spirit of vitriol; when these are well mixed by shaking them together, then add an ounce of corrosive sublimate in fine powder: mix all well together, and keep the whole in a bottle to be used for cleansing these foul wounds, and on any other occasion where there may be a detergent of this powerful kind necessary. It will keep good many years.

If this water will not thoroughly cleanse the wound, but there still will remain a quantity of foul matter in it, and there is danger of a gangrene, they add to it as much arsenic, in fine powder, as there was of the corrosive sublimate; that is, at the rate of an ounce to a quart and half a pint.

WREATH, in heraldry, a roll of fine linen or silk, like that of a Turkish turban, consisting of the colours borne in the escutcheon, placed in an achievement between the helmet and the crest, and immediately supporting the crest. See **CREST**, &c.

WRECK, or *Ship-Wreck*, in law, is when a ship perishes on the sea, and no person escapes alive out of it. In this case, if the ship so perished, or any part thereof, or the goods of the ship come to the land of any lord, and are left there, the lord shall have the same, as being a wreck of the sea: but if any single person, or even a dog, or other living creature, escape alive out of the ship, the party to whom the goods belong, may come within a year and a day, and proving the goods to be his, he shall have them again. And it is held, that they are no wrecks so long as they remain at sea, within the jurisdiction of the admiralty.

It is enacted by 12 Ann. c. 18. that if any wreck happen by any fault or negligence of master or mariners, the master must make good the loss; but if the same was occasioned by tempest, enemies, &c. he shall be excused: making holes in ships, or doing any thing wilfully tending to the loss thereof, is by that statute declared felony.

WRECK, in metallurgy, a vessel in which the third washing is given to the ores of metals.

WRESTLING, a kind of combat or engagement between two persons unarmed, body to body, to prove their strength and dexterity, and try which can throw his opponent to the ground.

It was the custom for the Athletæ to anoint their bodies with oil, to give the less hold to their antagonist. Lycurgus ordered the Spartan maids to wrestle in public, quite naked, in order to break them of their too much delicacy and niceness, to make them appear more robust, and to familiarize the people to such nudities.

WRIST, *Carpus*, in anatomy, a part of the hand, consisting of eight small, unequal, and irregular bones; all which taken together, represent a sort of grotto, of an irregular quadrangular figure, and connected principally with the basis of the radius. See the article **HAND**.

WRIST, in the manege. The bridle-wrist is that of the cavalier's left hand. A horseman's wrist and his elbow should be equally raised, and the wrist should

be two or three fingers above the pummel of the saddle.

WRIT, in law, signifies in general the king's precept in writing under seal, issuing out of some court, directed to the sheriff, or other officer, and commanding something to be done in relation to a suit or action, or giving commission to have the same done. And, according to Fitzherbert, a writ is said to be a formal letter of the king in parchment, sealed with his seal, and directed to some judge, officer, or minister, &c. at the suit of a subject, for the cause briefly expressed, which is to be determined in the proper court according to law.

WRIT of assistance, that issuing out of the exchequer, to authorize some persons to take a constable, or other public officer, to seize prohibited or unaccustomed goods or merchandize.

WRITER of the tallies, an officer of the exchequer, being clerk to the auditor of the receipt, who writes, upon the tallies, the whole letters of the teller's bill.

WRITING, *Scriptura*, the art or act of signifying and conveying our ideas to others, by letters, or characters, visible to the eye. See the articles **CHARACTER**, **LETTER**, **WORD**, &c.

Writing is now chiefly practised among us by means of

pen, ink, and paper; tho' the ancients had other methods.

To write without blacking the fingers, Mr. Boyle directs us as follows. Prepare the paper with a fine powder made of three parts of calcined copperas, two of galls, and one of gum arabic; those being fresh mixed, rub them with a hare's foot into the pores of the paper, and write with fair water, and the black letters will immediately appear.

To make new writing appear old, the same author directs to moisten it well with oil of tartar per deliquium, more or less diluted with water, as you desire the ink to appear more or less decayed.

We may write without ink or its materials. For this purpose take a fine powder of calcined hartshorn, of clean tobacco pipes, or rather of mutton-bones burnt to a perfect whiteness, and rub it upon the paper, and then write with a silver bodkin, or the like.

WRONG, in a logical sense. See **ERROR**, **FALSEHOOD**, **TRUTH**, &c.

WYCH-HOUSE, a house in which salt is boiled.

WYTE, or **WITE**, in our ancient customs, a pecuniary penalty or mulct. The Saxons had two kinds of punishments, were and wyte; the first for the more grievous offences, and the latter for the lesser ones.

X.

X E R

X, A double consonant, and the twenty-second letter of the English alphabet.

The letter **X** was not used by the Hebrews or ancient Greeks; for as it is not a simple but compound letter, the ancients, who used great simplicity in their writings, expressed it by *cs*, the letters which compose it; thus, instead of the modern $\pi\lambda\epsilon\chi\omega$, the ancient Attics wrote $\pi\lambda\epsilon\sigma\omega$.

X, is also a numeral letter, signifying ten, as it represents two **V**'s placed one on the top of the other. When laid flat, thus $\times$, it signifies a thousand; and when a dash is added over it, as $\bar{X}$, it signifies ten thousand.

XANTHICA, in antiquity, a Macedonian festival, so called because it was observed in the month Xanthus, which, as Suidas tells us, was the same with April. At this time the army was purified by a solemn lustration, in the following manner: they divided a bitch into two halves, one of which, together with the entrails, was placed upon the right hand, the other upon the left; between these the army marched in this order; after the arms of the Macedonian kings came the first part of the army; these were followed by the king and his children, after whom went the life-guards, and the rest of the army. This done, the army was divided into parts, one of which being set in array against the other, there followed a short encounter, in imitation of a fight.

XANTHIUM, the lesser burdock, in botany, a genus of plants, producing male and female flowers; the corolla is compound, uniform, tubulose, and equal, and disposed in an hemispherical form; the partial flower is monopetalous, tubulose, funnel-shaped, erect, and divided into five segments at the limb: the fruit is a dry ovato-oblong berry, bifid at the apex, hairy, and covered

X Y L

with hooked prickles, containing an oblong seed, plane on one side, and convex on the other. See the article **BARDANA**.

XERANTIMUM, the Austrian sneeze-wort, in botany, a genus of plants, whose flower is compound and unequal; the corollulæ, which form the disc, are tubulose and hermaphrodite; and a few female quinquifid florets compose the radius: there is no pericarpium; but the cup, which is imbricated and cylindric, contains the seeds, which are oblong and crowned with hair.

The flowers of these plants being gathered when full blown, and properly dried, will continue fresh and beautiful several months; and by dipping them into various tinctures, they may be stained of different colours. They are propagated by sowing the seeds, either in spring or autumn, and afterwards the plants should be set where they are intended to blow.

XEROPHAGIA, in church-history, the eating of dried foods: so the ancient Christians called certain fast days, on which they eat nothing but bread and salt, and drank only water: sometimes they added pulse, herbs, and fruits. This sort of fasting was observed chiefly in the holy week, out of devotion, and not by obligation.

XESTA, an Attic measure of capacity. See **MEASURE**.

XIPHIAS, the sword-fish, in ichthyology, a genus of fishes. The rostrum, or extremity of the head, is continued forward, with an extremely long point, of a depressed, or somewhat flattened figure, resembling the blade of a sword, and of a bony structure; the lower jaw is acute, and of somewhat a triangular figure; the body is oblong, and of a roundish figure, and is considerably thick in proportion to its length; the back is convex,

convex, and the sides are rounded; there is no belly fins, and on the back there is only one fin, which is very long, and lowest in the middle; the branchiofstege membrane on each side contains only eight bones. About fifteen feet in length is the size of a moderately large one, but not unfrequently it is met with much bigger.

XIPHIAS, is also a fiery meteor, in form of a sword. It differs from the acontias in this, that the latter is longer, and more like a dart; and the former shorter and broader in the middle.

XIPHION, in botany, a genus of plants, differing from the iris by having a bulbous root and subulated leaves; but by Linnæus is classed among them. See IRIS.

XIPHOIDES, in anatomy, a cartilage adhering to the sternum; called also cartilago ensiformis. See STERNUM.

XYLO-ALOES, or ALOE-WOOD, in pharmacy, a drug distinguished into three sorts; the calambac, the common lignum aloes, and calambour.

The calambac, or finest aloe-wood, called by authors, lignum aloes prestantissimum, and, by the Chinese, fukhiang, is the most resinous of all the woods we are acquainted with: it is of a light spongy texture, very porous, and its pores so filled up with a soft and fragrant resin, that the whole may be pressed and dented by the fingers like wax, or moulded about by chewing in the mouth, in the manner of mastic.

This kind, laid on the fire, melts in great parts like resin, and burns away in a few moments, with a bright flame and perfumed smell. Its scent, while in the mass, is very fragrant and agreeable; and its taste acrid and bitterish, but very aromatic and agreeable: it is so variable in its colour, that some have divided it into three kinds; the one variegated with black and purple; the second, with the same black, but with yellowish instead of purple; and the third, yellow alone, like the yolk of an egg: this last is the least scented of the three; the substance, however, in them all, is the same in every respect, except the colour. It is brought from Cochinchina.

The lignum aloes vulgare, is the second in value. This is of a more dense and compact texture, and consequently less resinous than the other: there is some of it, however, that is spongy, and has the holes filled up with the right resinous matter; and all of it, when good, has veins of the same resin in it.

We meet with it in small fragments, which have been cut and split from larger; these are of a tolerably dense texture, in the more solid pieces, and of a dusky brown colour, variegated with resinous black veins. It is in this state very heavy, and less fragrant than in those pieces which shew a multitude of little holes, filled up with the same blackish matter that forms the veins in others. The woody part of these last pieces is somewhat darker than the other, and is not unfrequently purplish, or even blackish. The smell of the common aloe-wood is very agreeable, but not so strongly perfumed as the former. Its taste is somewhat bitter and acrid, but very

aromatic. This is also brought from Cochinchina, and sometimes from Sumatra.

The calambour, or, as some write it, the calambouc, is also called agallochum sylvestre, and lignum aloes Mexicanum. It is a light and friable wood, of a dusky and often mottled colour, between a dusky green black, and a deep brown. Its smell is fragrant and agreeable, but much less sweet than that of either of the others; and its taste bitterish, but not so much acrid or aromatic as either of the two former. We meet with this very frequently, and in large logs; and these sometimes entire, sometimes only the heart of the tree, the cortical part being separated. This is brought from the island of Timor, and is the aloe-wood used by the cabinet-makers and inlayers.

The Indians use the calambac by way of incense, burning small pieces of it in the temples of their gods; and sometimes their great people burn it in their houses, in times of feasting.

It is esteemed a cordial, taken inwardly; and they sometimes give it in disorders of the stomach and bowels, and to destroy worms. A very fragrant oil may be procured from it, by distillation, which is recommended in paralytic cases, from five to fifteen drops. It is at present, however, but little used, and would scarce be met with any where in the shops, but that it is an ingredient in some of the old compositions.

XYLO BALSAMUM, a name which naturalists give to the wood of the tree which yields that precious gum known to the Latins by the name of opobalsamum, and to us by the name of balm of Gilead.

We have branches of this tree brought from Cairo; they are very straight, brittle, unequal, and full of knots; their bark is reddish without, and greenish within.

The xylo-balsamum is reputed good to strengthen the brain and stomach, and to expel poison. See BALSAM.

XYLO-CASSIA, in the materia medica, the same with the cassia-ligna. See CASSIA.

XYLON, in botany, a name used by some authors for the bombax of Linnæus. See the article COTTON.

XYLOPIA, in botany, a genus of plants, whose flower consists of six sessile, linear, lanceolated, coriaceous petals, the three outward ones being larger: the stamina have no filaments, but consist of numerous antheræ sitting on the germen: the fruit is a dry, roundish, unilocular drupe, containing a roundish kernel.

XYSTARCHA, in antiquity, the master or director of the xyftus. In the Greek gymnasium, the xyftarcha was the second officer, and the gymnasiarcha the first; the former was his lieutenant, and presided over the two xyfti, and all exercises of the athletæ therein.

XYSTUS, among the Greeks, was a long portico, open or covered at the top, where the athletæ practised wrestling and running: the gladiators, who practised therein, were called xyftici.

Among the Romans, the xyftus was only an alley or double row of trees, meeting like an arbour, and forming a shade to walk under.

Y.

Y A R

Y, The twenty-third letter of the English alphabet.

The letter Y was not in the ancient Hebrew alphabet, though they were not without the sound of it in their *yod*, if the pronunciation of the ancient Jews was the same as the modern.

The figure of the letter Y was doubtless derived from that of the V, for they seem to have been both the same letter in the most ancient Greek alphabet; for V is in the fifth line, and Y in the seventh of the Sigeian inscription, for the same letter. It is formed by expressing the breath with a sudden expansion of the lips from the configuration by which we express the vowel *u*.

Y is one of the ambigeneal letters, being a consonant at the beginning of words, and placed before all vowels; as *yarn*, *year*, *young*, &c. And, at the end of words, it is a vowel, and is substituted for the sound of *i*, as in *my*, *desery*, *deny*, &c. Y, is also a numeral letter signifying 150, or according to Baronius, 159.

When a dash was added at top, *Ȳ*, it signified, 150,000. Pythagoras used the *y* as a symbol of human life; the foot representing infancy, and the forked top the two paths of virtue and vice, one or the other of which people are to enter upon, after attaining to the age of discretion.

YACHT, or **YATCH**, a vessel with one deck, carrying from four to twelve guns. See **SHIP**.

YARD, a measure of length used in England and Spain, chiefly to measure cloth, stuffs, &c. See **MEASURE**.

YARD, in anatomy. See **PENIS**.

YARD-LAND, is taken to signify a certain quantity of land, in some countries being fifteen acres, and in others twenty; in some twenty-four, and in others thirty and forty acres.

YARDS of a Ship, are those long pieces of timber which are made a little tapering at each end, and are fitted each athwart its proper mast, with the sails made fast to them, so as to be hoisted up, or lowered down, as occasion serves. See the article **SHIP**.

YARD-ARM, is that half of the yard that is on either side of the mast, when it lies athwart the ship.

YARDS, also denote places belonging to the navy, where the ships of war, &c. are laid up in harbour. There are belonging to his majesty's navy, six great yards, viz.—Chatham, Deptford, Woolwich, Portsmouth, Sheerness, and Plymouth; these yards are fitted with several docks, wharfs, launches, and graving places, for the building, repairing, and cleaning of his majesty's ships; and therein are lodged great quantities of timber, masts, planks, anchors, and other materials: there are also convenient store-houses in each yard, in which are laid up vast quantities of cables, rigging, sails, blocks, and all other sorts of stores, needful for the royal navy.

YARE, among sailors, implies ready or quick: as, be yare at the helm; that is, be quick, ready, and expeditious at the helm. It is sometimes also used for bright by seamen: as, to keep his arms yare; that is, to keep them clean and bright.

YARN, wool, or flax, spun into thread, of which they weave cloth. See **CLOTH**, **WOOL**, &c.

Y A W

Yarn is ordered after the following manner: after it has been spun upon spindles, spools, or the like, they reel it upon reels, which are hardly two feet in length, and have but two contrary cross-bars, being the best, and the least liable to ravelling. In reeling of fine yarn, the better to keep it from ravelling, you must, as it is reeled, with a tie-band of big-twist, divide the slipping or skain into several leys, allowing to every ley eighty threads, and twenty leys to every slipping, if the yarn is very fine; otherwise less of both kinds. The yarn being spun, reeled, and in the slippings, the next thing is to scour it. In order to fetch out the spots, it should be laid in lukewarm water for three or four days, each day shifting it once, wringing it out, and laying it in another water of the same nature: then carry it to a well or brook, and rinse it till nothing comes from it but pure clean water: that done, take a bucking-tub, and cover the bottom thereof with very fine ashen ashes; and then having opened and spread the slippings, covering them with ashes as before; and thus lay one upon another, till all the yarn be put in: afterwards cover the uppermost yarn with a bucking cloth, and in proportion to the bigness of the tub; lay therein a peck or two more of ashes: this done, pour upon the uppermost cloth a great deal of warm water, till the tub can receive no more, and let it stand so all night. Next morning you are to set a kettle of clean water on the fire; and when it is warm, pull out the spigot of the bucking-tub, to let the water run out of it, into another clean vessel; as the bucking-tub wastes, fill it up again with the warm water on the fire: and as the water on the fire wastes, so likewise fill that up with the ley that comes from the bucking-tub; ever observing to make the ley hotter and hotter, till it boils: then you must, as before, ply it with the boiling ley at least four hours together, which is called the driving of a buck of yarn. See **BLEACHING**.

YARRINGLE, a kind of instrument, or reel on which hanks of yarn are wound, to clues or balls. See **REEL**.

YAWNING, *Oscitatio*, an involuntary opening of the mouth, occasioned by a vapour, or ventosity, endeavouring to escape, and generally witnessing an irksome weariness, or an inclination to sleep.

Yawning, according to Boerhaave, is performed by expanding, at one and the same time, all the muscles capable of spontaneous motion; by greatly extending the lungs; by drawing in gradually and slowly a large quantity of air, and gradually and slowly breathing it out, after it has been retained for some time, and rarified, and then restoring the muscles to their natural state. Hence, the effect of yawning is to move, accelerate, and equally distribute all the humours through all the vessels of the body, and, consequently, to qualify the muscles and organs of sensation for their various functions.

Sanctorius observes, that a great deal is insensibly discharged, when nature endeavours to get rid of the retained perspirable matter, by yawning and stretching of the limbs. To these a person is most inclined just after sleep, because a greater quantity going off by the pores of the skin, than at other times, whensoever a person wakes,

wakes, the increased contraction that then happens, closes a great deal of the perspirable matter in the cutaneous passages, which will continually give such irritations, as excite yawning and stretching; and such motions, by shaking the membranes of the whole body, and shifting the contacts of their fibres and the inclosed matter, by degrees throw it off. Hence we see the reason, why healthful strong people are most inclined to such motions, because they perspire most in time of sleep, and therefore have more of the perspirable matter to lodge in the pores, and greater irritations thereunto.

YAWS, in the sea-language. A ship is said to make yaws when she does not steer steady, but goes in and out when there is a stiff gale.

YAWS, a distemper endemial to Guinea and the hotter climates in Africa.

It makes its first appearance in little spots on the cuticle, not bigger than a pin's point, which increase daily, and become protuberant, like pimples. Soon after, the cuticle frets off; and then, instead of pus or ichor, there appears white sloughs or fordes, under which is a small red fungus. These increase gradually, some to the size of a small wood-strawberry, others to that of a raspberry; others again exceed the largest mulberry, which in shape they very much resemble. In the mean time, the black hair growing in the yaws turns to a transparent white. See **CUTICLE**, &c.

It is not easy to determine the exact time which the yaws take in going through their different stages. Lusty well fed negroes have had several yaws as big as a mulberry in a month's time; whereas the low in flesh, with a scanty allowance, have passed three months without their growing to the size of a strawberry.

They appear in all parts of the body, but are most plentiful, and of the largest size, about the groin, privy parts, anus, arm-pits, and face; they are largest when fewest in number, and *vice versa*. They are not painful, unless handled roughly, nor cause a loss of appetite. They continue long without any sensible alteration; and some are of opinion, that as soon as the funguses become dry, the infection is exhausted.

The yaws are not dangerous, if the cure is skilfully managed at a proper time. But if the patient has been once salivated, or has taken any quantity of mercury, and his skin once cleared thereby, the cure will be very difficult, if not impracticable. The following form of medicine is recommended as a cure: Take of flowers of sulphur, one scruple; of camphor dissolved in spirit of wine, five grains; of theriaca Andromachi, one dram; and as much syrup of saffron as will make a bolus. Let the bolus be taken at going to rest, which must be repeated for a fortnight or three weeks, till the yaws come to the height. Then throw the patient into a gentle salivation, with calomel given in small doses, without farther preparation. After salivation, sweat the patient twice or thrice, on a frame or chair, with spirit of wine, and give the following electuary: of æthiops mineral, one ounce and a half; of gum guaiacum, half an ounce; theriaca andromachi, and conserve of red roses, of each one ounce; oil of sassafras, twenty drops; and as much of syrup of saffron as is requisite for an electuary. Of this, let two drams be taken in the morning and at night. He may likewise drink the decoction of guaiacum and sassafras fermented with molasses, for his constant drink, while the electuary is taking, and a week or a fortnight after the electuary is spent.

Sometimes there remains one large yaw, high and knobbed, red and moist; this is called the master-yaw. This must be consumed an eighth or a tenth part of an inch below the skin, with corrosive red mercury, and burnt alum, of each an equal quantity; and digested with one ounce of yellow basilicon, and one dram of red corrosive mercury; and cicatrized with lint pressed out of spirit of wine, and with the vitriol stone.

YEAR, *Annus*, the time the sun takes to go through the twelve signs of the zodiac. This is properly the natural or tropical year, and contains 365 days, 5 hours, and 49 minutes. See the articles **SIGN** and **ZODIAC**.

As for the Gregorian, the civil, the solar or astronomical, the bissextile, and Platonic years, see them under the articles **GREGORIAN**, **CIVIL**, &c.

The Julian year derives both its name and institution from Julius Cæsar the dictator; for before his time the form of the Roman year was so corrupted by the indiscretion of the pontiffs, in whose hands the power of intercalation was lodged, that the winter-months fell back to the autumn, and those of autumn to the summer. To remedy these inconveniences, the dictator not only added to that year, in which he set about the reformation of the calendar, the common intercalation of 23 days, between the 23d and 24th days of February, pursuant to Numa Pompilius's institution, but likewise 67 days more between November and December; so that this year contained 445 days. This done, he instituted a solar year, of 365 days and 6 hours, pursuant to what he had learned from the Egyptians, and every fourth year he ordered a day to be added. See **JULIAN PERIOD**.

The Arabs, Saracens, and Turks, count their year by the motion of the moon, making it consist of 12 moons, or months; whereof some have 30, and some 29 days, alternately; and these altogether make 354 days, and constitute a common lunar year: and 354 days, 8 hours, 48 minutes, 38 seconds, 12 thirds, constitute what is called a lunar astronomical year.

The Greeks counted their year by the motion of both sun and moon; and finding that there was 11 days difference between the lunar and solar years, at first they added an intercalary month every two years, containing 22 days. Afterwards, considering the 6 hours also, they put their embolism off 4 years, and then making the 3 first years to contain 354 days each, this made the fourth year to have 399 days: and to make this intercalation the more remarkable, they instituted the Olympic games on every such fourth year; whence came the computation by Olympiads. See **OLYMPIAD**.

The Egyptians had two sorts of years, the erratic and the fixed, or ætiac. The erratic was called the Nabonassarean, from the epocha which takes its rise from Nabonassar, king of the Chaldees. As it neglects the 6 hours, which, in the Julian form, make a leap-day once in four years, its beginning anticipates the Julian every fourth year by a day, and therefore it is justly called erratic.

The anticipation of 1 day in 4 years, gains of the Julian years 1 in 1460; so that 1461 Nabonassarean years make but 1460 Julian years.

The fixed Egyptian year observes the Julian form of 365 days and 6 hours, making a leap-day of the 6 hours once in 4 years. It differs from the Julian in this, that its months are the same with those of the Nabonassarean; that it begins on August 29, instead of January 1; or on August 30, if it be a leap-year; that it takes in the leap-day, not in February, but at the end of the year. See **EPOCHA** and **INTERCALARY**.

The Persian erratic year goes by the name Yezdegerdic, by reason that the Persian epocha commences from the death of Yezdegird, the last Persian king, who was killed by the Saracens. It consists of 12 months, containing 30 days each, and 5 supernumerary ones; so that it differs from the Nabonassarean only in the names of the months, and the commencement of the epocha.

The Gelalean year, used also by the Persians, is very well adapted to the solar motions. It takes in a leap-day every fourth year, but every sixth or seventh turn it throws it forward to the fifth year, by which means the equinoxes and solstices are fixed to almost the same days of the month.

The Syriac year consists of 365 days and 6 hours, being divided into 12 months of equal extent with those of the Julian year, to which they correspond. This year begins October 1, so that the month called Tishrim, agrees with our October. The astronomical year is two-fold, viz. the tropical and sidereal; by the latter, is meant that space of time which the sun takes in departing from a fixed star, and returning to the same again. This year consists of 365 days, 6 hours, and 10 minutes.

As the form of the year is various among different nations, so likewise is the beginning: the Jews began their ecclesiastical year with the new moon of that month whose full moon happens next after the vernal equinox; and every seventh year they kept as a sabbatic year, during

ing which they let their land lie at rest. The ancient Jewish year was made to agree with the solar year, by the adding of 11, and sometimes of 12 days, at the end of the year, or by an embolismic month.

The beginning of the Athenian or Attic year, was reckoned from that new moon, the full moon of which comes next after the summer solstice.

The Macedonian lunar year agrees with the Athenian, excepting that the former takes its beginning, not from the summer-solstice, but from the autumnal equinox.

The Ethiopic year is a solar year, agreeing with the actiac or fixed Egyptian year, except in this, that the names of the months are different, and that it commences, with the Egyptian year, on Aug. 29, of the Julian year.

The Arabian or Mahometan year is called also that of the hegira, because the calculation of these years runs from the epocha of the hegira, when Mahomet fled from Mecca to Medina: they had twelve civil months in a year, which contained 29 and 30 days, by turns, abating for their leap years, in which the month Dultreggia has always 30. See HEGIRA.

The Mahometans begin their year when the sun enters Aries; the Persians, in the month answering to our June; the Chinese, and most of the Indians, begin it with the first moon in March: at Rome there are two ways of computing the year, the one beginning at the nativity of our Lord, which the notaries use; the other in March, on occasion of the incarnation, and it is from this the bulls are dated. The civil or legal year, in England, as well as the historical year, commences Jan. 1, by the late act for the alteration of the style: the church, as to her solemn service, begins the year on the first Sunday in Advent, which is always that next St. Andrew's day.

YEAR AND DAY, in law, signifies a certain time that by law determines a right, or works prescription in divers cases; as in the case of an estray, if the owner do not challenge it within that time, it becomes forfeited to the lord; so of a wreck, &c. The like time is given to prosecute appeals in; and where a person wounded, dies in a year and a day after the wound received, it makes the offender guilty of murder.

YELLOW, one of the original colours of light. See COLOUR and LIGHT.

YELLOW, in dyeing, is one of the five simple and mother colours.

For the finest yellows, they first boil the cloth or stuff in alum or pot-ashes, and give the colour with weld or wold.

Likewise turmeric gives a good yellow, though not the best.

There is also an Indian wood, that gives a yellow colour bordering on gold. There is another sort of yellow, made of saffron; but this is inferior to them all.

With yellow, red of madder, and that of goat's hair prepared with madder, are made the gold yellow, aurora, thought-colour, macarate, isabella, chamoise-colour, which are all casts or shades of yellow. Painters or enamellers make their yellow of masticote, which is cerufs raised to a yellow colour by the fire, or with oker. Limners and colourers make it with saffron, French berries, orcanette, &c. Mr. Boyle tells us a most beautiful yellow may be procured by taking good quick silver, and three or four times its weight of oil of vitriol, and drawing off, in a glass retort, the saline menstruum from the metalline liquor, till there remains a dry snow-white calx at the bottom: on pouring a large quantity of fair water on this, the colour changes to an excellent light yellow.

He says, he fears this colour is too costly to be used by painters: and he does not know how it would agree with every pigment, especially oil colours.

YELLOWs, a disease in a horse, much the same with that called the jaundice in man.

There are two kinds of it, the yellow and the black. The yellow is a very frequent disorder, say the farriers, arising from obstructions in the gall-pipe, or the little ducts opening into the same, occasioned by viscid or gritty matter lodged therein, or a plenitude and compression of the neighbouring blood-vessels, by means of

which the matter that should be turned into gall, is taken up by the vein, and carried into the mass of blood, which it tinctures yellow; so that the eyes, inside of the lips, and other parts of the mouth capable of shewing the colour, appear yellow. The effect whereof is, that a horse will be dull, heavy, and low spirited, easily jaded by the least labour or exercise, &c.

The black is known by other symptoms: the whites of the eyes, mouth, and lips turn to a dusky colour, and are not so clear and sanguine as before.

For the cure of this disease, we are directed to dissolve an ounce of mithridate in a quart of ale, or beer, and give it the horse lukewarm; or instead of mithridate, two ounces of Venice-treacle; and if that is not to be had, three spoonfuls of common treacle.

This distemper is also incident to black cattle. The cure is to bleed them in the ears, eyes, and in the tail; to put salt into their ears, and to rub them between your hands: and being blooded, give them two handfulls of salt down their throats, dry over night. In the morning let them have fenugreek, turmeric, long-pepper, anniseed, and liquorice, but two pennyworth in all, made into a powder, and given in a quart of ale milk-warm.

YEOMAN, the first or highest degree among the plebeians of England, next in order to the gentry.

The yeomen are properly freeholders, who having land of their own, live on good husbandry.

YEOMAN is also a title of office in the king's household, of a middle place or rank between an usher and a groom.

YEOMEN of the Guard were anciently two hundred and fifty men of the best rank under gentry, and of larger stature than ordinary, each being required to be six feet high.

At present there are but one hundred yeomen in constant duty, and seventy more not in duty; and as any of the hundred dies, his place is supplied out of the seventy.

They go dressed after the manner of king Henry VIII's time. They formerly had diet as well as wages, when in waiting; but this was taken off in the reign of queen Anne.

YERKING, in the manege, is when a horse strikes with his legs, or flings and kicks back with his whole hind quarters, stretching out the two legs nearly together, and even to their full extent.

YEST, YEAST, or BARM, a head, or scum rising upon beer or ale, while working or fermenting in the vat.

It is used for a leaven or ferment in the baking of bread, as serving to swell or puff it up very considerably in a little time, and to make it much lighter, softer, and more delicate. When there is too much of it, it renders the bread bitter.

The faculty of medicine of Paris, by a decree of March 24, 1688, solemnly maintained it noxious to the health of the people: yet could not that prevent its progress.

YEW, *Taxus*, in botany. See TAXUS.

YEW, is also a term used by the salt-workers of Ly-mington, and some other parts of England, to express the first rising of a scum upon the brine in boiling. See SALT.

YIELD, or SLACK the hand, in the manege, is to slack the bridle, and give the horse head.

YNCA, or INCA, an appellation anciently given to the kings of Peru, and princes of the blood; the word literally signifying lord, king, emperor, and royal blood.

YOAK, or YOKE, in agriculture, a frame of wood, fitted over the necks of oxen, whereby they are coupled together, and harnessed to the plough.

The Romans made the enemies they subdued, pass under the yoke, which they called *sub jugum mittere*; that is, they made them pass under a sort of *furca patibulares*, or gallows, consisting of a pike, or other weapon, laid across two others, planted upright in the ground.

Sea-YOAK.—When the sea is so rough, that the helm cannot be governed by the hands, the seamen make a yoak to steer by; that is, they fix two blocks to the end

of the helm, and reeving two small ropes through them, which they call falls, by having some men at each tackle, they govern the helm by direction. They have another way of making a sea-yoak, by taking a double turn about the end of the helm with a single rope, the ends being laid to the ship's sides, by means of which they guide the helm.

YOLK, or **YELK**, in natural history, the yellow part in the middle of the egg.

YOUTH, see the article **ADOLESCENCE**.

YOUTH, *Juventus*, in the Pagan theology, a goddess worshipped among the Romans, who, together with the gods Mars and Terminus, kept her place in the capitol along with Jupiter, when the other deities were turned out; whence the Romans drew a lucky omen for the durability of their empire.

YPSILOIDES, in anatomy, the third genuine suture of the cranium, thus called from its resembling a Greek ψ , or ypsilon.

YUCCA, in botany, a genus of plants, whose flower is campanulated, and divided into six large ovate petals, cohering at their base: the stamina are six short filaments, topped with small antheræ: the fruit is an oblong trifid capsule, obtusely triangular, and divided into three cells, which contain many seeds laying over each other in a double order.

The yucca has much the appearance of the aloe, and is propagated in the same manner; and from the dried root of a species, a kind of bread is made by the Indians.

Z.

Z A I

Z, The twenty fourth and last letter, and the nineteenth consonant of our alphabet; the sound of which is formed by a motion of the tongue from the palate downwards and upwards to it again, with a shutting and opening of the teeth at the same time.

This letter has been reputed a double consonant, having the sound *ds*; but some think with very little reason; and, as if we thought otherwise, we often double it, as in *puzzle*, *muzzle*, &c.

Among the ancients **Z** was a numeral letter, signifying two thousand; and with a dash at top, **Z̄** signified two thousand times two thousand, or four millions.

In abbreviations, this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it was in the earlier times used to express the third part of one ounce, or eight scruples. **ZZ** were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zinziber, or ginger.

ZAFFER, or **ZAFFRE**, in chemistry, the name of a blue substance, of the hardness and form of a stone; and generally supposed to be a native fossil.

It is in reality, however, a preparation of cobalt; the calx of that mineral being mixed with powdered flints, and wetted with water to bring it into this form. See **COBALT**.

To prepare this for use in the glass-trade, put it in the furnace; then put it into an iron ladle to be heated red-hot, and sprinkle it with strong vinegar; and when cold, grind it on a porphyry to an impalpable powder; then throw this into water in glazed earthen pans; and when it has been well stirred about, let it settle, and pour off the water: repeat this washing often, and the foulness of the zaffre will be thus wholly separated: dry the powder, and keep it for use.

ZAIRAGIA, a kind of divination in use among the Arabs, performed by means of divers wheels or circles placed concentric to one another, and noted with several letters, which are brought to answer to each other by moving the circles according to certain rules.

Z E A

ZANNICHELLIA, in botany, a genus of plants, producing male and female flowers; the male flower hath neither cup or corolla, consisting only of a long, erect, single filament, topped with an ovate anthera; the female flower, which is placed near the filament, has no corolla, but consists of a monophyllous ventricose cup, which is scarce visible, and four corniculated germina, which join together, and afterwards become the same number of oblong seeds, which are acuminate on both sides.

ZANONIA, in botany, a genus producing male and female flowers on distinct plants; the male flower is monopetalous, and divided into three pointed inflexed segments, with five patent stamina; the corolla of the female flower is like that of the male, and the fruit is a long, very large, truncated berry, attenuated at the base; it contains three cells, in each of which are placed two seeds, of an oblong-roundish figure.

ZAPATA, or **SAPATA**, a kind of feast or ceremony held in Italy, in the courts of certain princes, on St. Nicholas's day; wherein people hide presents in the shoes or slippers of those they would do honour to, in such a manner as may surprise them on the morrow when they come to dress; being done in imitation of St. Nicholas, who used, in the night-time, to throw purses of money in at the windows, to marry poor maids withal.

ZEA, Indian corn, in botany, a genus of plants, producing male and female flowers in spikes; the corolla of the male flower is a bivalvular glume, with two compressed very short nectaria: the stamina are three capillary filaments, topped with quadrangular antheræ; the corolla of the female flower consists of two membranaceous, broad, persistent valves: there is no pericarpium; but the seeds, which are roundish, and compressed, are half inclosed in a large long receptacle.

ZEAL, $\zeta\eta\lambda\omicron\varsigma$, the exercise of a warm animated affection, or passion, for any thing. See the article **PASSION**.

ZEALOTS, an ancient sect of the Jews, so called from their pretended zeal for God's laws, and the honour of religion. The Zealots were a most outrageous and ungovernable people; and on pretence of asserting God's laws, and a strictness and purity of religion, assumed a liberty of questioning notorious offenders without staying for the ordinary formalities of law.

ZEBRA,

ZEBRA, the wild ass, in zoology, a species of equus, transversely striated.

It is an extremely beautiful animal, and though in colouring so much different from all other kinds and varieties of equus, agrees with it in all other respects: it is about equal to the common ass in size, but of a much more elegant figure; the head is small and short, the ears are long, the eyes are large and bright, and the mouth considerably large; the neck is long and slender, but elegantly turned; the body is rounded, and small in comparison of that of the common ass; the legs are long and slender, the tail long and beautiful, but hairy only at the end.

The whole animal is party-coloured, or beautifully striped in a transverse direction, with long and broad streaks, alternately of a deep, glossy, and shining brownish and whitish, with some absolutely black. It is a native of many parts of the East.

ZECHARIAH, a canonical book of the Old Testament, containing the predictions of Zechariah, the son of Barachia, and grandson of Iddo. He is the eleventh of the twelve lesser prophets.

Zechariah entered upon the prophetic office at the same time with Haggai, and was sent to the Jews upon the same message, to reprove them for their backwardness in erecting the temple, and restoring divine worship; but especially for the disorder of their lives and manners, which could not but derive a curse upon them. By several notable visions and types, he endeavours to confirm their faith, and establish their assurance concerning God's providence with them, and care over them; and as a proof and demonstration of this, he intersperses the most comfortable promises of the coming of the kingdom, the temple, the priesthood, the victory, the glory of Christ the Branch. Nor does he forget to assure them of the ruin of Babylon, their most implacable enemy. This prophet is the longest and most obscure of all the lesser prophets, his style being interrupted and without connection.

ZEDOARY, in the materia medica, a root, the several pieces of which differ so much from one another in shape, that they have been divided into two kinds, as if two different things, under the names of the long and round zedoary, being only the several parts of the same root.

The long pieces of zedoary are of a very singular figure; they are not of the nature of the common long roots of plants, but are, themselves, properly tubera or glandules, as well as the round ones, differing from them in nothing but their oblong figure: they are two, three or four inches in length, and of the thickness of a man's finger; not large at one end, and tapering away to the other, but thickest in the middle, and growing gradually smaller to each end, where they terminate in an obtuse point each way: they are of a tolerable smooth surface, except that they have some little protuberances in several parts from which fibres have originally grown: they are of a very close and compact texture, considerably heavy, and very hard; they will not cut easily with a knife; when cut, they shew a fine, smooth, and glossy surface; they are of a pale greyish colour on the outside, with a faint mixture of brown, and are of a dead whitish hue within: they are not easily powdered in the mortar; their smell, while bruising, is very remarkable, and is highly aromatic, and of a bitterish taste. The round zedoary has all the same characters with this, and differs only in figure, being short and roundish, of the size of a small walnut, smooth on the surface, except where the bundles of fibres have adhered, and generally running into a sharp point at the end.

Zedoary is to be chosen fresh, sound, and hard, in large pieces; it matters not as to shape, whether long or round; of a smooth surface, and of a sort of fatty appearance within, too hard to be bitten by the teeth, and of the briskest smell that may be; such as is friable, dusty, and worm-eaten, is to be rejected.

The ancient Greeks were wholly unacquainted with zedoary; there is no mention of any such drug in the works of Dioscorides or Galen. The Arabians, however, were well acquainted with it; they mention it

sometimes under the name of zedoary, and sometimes under that of zerumbeth; but are so short in their descriptions, and so at variance among one another, that it is not easy to ascertain their meaning, as to the distinction, if they originally meant any, between the substances expressed by these two names.

Serapio and Rhazes use the words zedoaria and zerumbeth as synonymous, and declare both to mean only the same root. Avicenna, on the contrary, distinguishes the zedoary and zerumbeth, and even talks of two kinds of zedoary. Others of them make the zarnab they speak of different both from the zedoary and zerumbeth; but Serapio, an author as much to be depended upon for his accuracy as any of them, declares zedoary, zerumbeth, and zarnab, all to be the same thing.

Zedoary both of the long and round kind, is brought us from China; and we find by the Arabians, that they also had it from the same place. The round tubera are less frequent than the long, and some of them have, therefore, supposed them the produce of a different and more rare plant; but this is not so probable as that the general form of the root is long, and the round tubera are only *lufus naturæ*, and less frequent in it.

The plant which produces it, is one of the class of the herbæ bulbosæ affines of Mr. Ray. It is described in the *Hortus Malabaricus*, under the name *malan kua*. Zedoary, distilled with common water, affords a thick and dense essential oil, which soon concretes of itself into a kind of camphor, and on this oil its virtues principally depend. It is a sudorific, and is much recommended by some in fevers, especially of the malignant kinds. It is also given with success as an expectorant in all disorders of the breast arising from a tough phlegm, which it powerfully incises and attenuates; it is also good against flatulencies, and in the cholic; it strengthens the stomach, and assists digestion; and, finally, is given with success in nervous cases of all kinds.

ZEND, or **ZENDAVESTA**, a book containing the religion of the magicians, or worshippers of fire, who were disciples of the famous Zoroaster.

This book was composed by Zoroaster during his retirement in a cave, and contained all the pretended revelations of that impostor. The first part contains the liturgy of the magi, which is used among them in all their oratories and fire temples to this day; they reverence it as the Christians do the bible, and the Mahometans the Koran. There are found many things in the zend taken out of the scriptures of the Old Testament, which Dr. Prideaux thinks is an argument that Zoroaster was originally a Jew. Great part of the psalms of David are inserted in the zend; he makes Adam and Eve to have been the first parents of mankind, and gives the same history of the creation and deluge as Moses does, and commands the same observances about clean and unclean beasts, the same law of paying tythes to the sacerdotal order, with many other institutions of Jewish extraction. The rest of its contents are an historical account of the life, actions, and prophecies of its author, with rules and exhortations to moral living. The Mahometans have a sect which they call Zendikites, who are said to be the Sadducees of Mahometanism, denying Providence and the resurrection, believing the transmigration of souls, and following the zend of the magi.

ZENITH, in astronomy, the vertical point; or a point in the heavens directly over our heads.

The zenith is called the pole of the horizon, because it is ninety degrees distant from every point of that circle.

ZENITH DISTANCE, is the complement of the meridian altitude of any heavenly object: or it is the remainder, when the meridian altitude is subtracted from ninety degrees.

ZENSUS, in arithmetic, a name given to a square number, or the second power, by some authors.

ZEPHANIAH, a canonical book of the Old Testament, containing the predictions of Zephaniah the son of Cushi, and grandson of Gedaliah; being the ninth of the twelve lesser prophets. He prophesied in the time of king Josiah, a little after the captivity of the ten tribes, and before that of Judah; so that he was cotemporary with Jeremiah.

ZEPHYR,

ZEPHYR, *Zephyrus*, the west wind; or that which blows from the cardinal point of the horizon opposite the east.

ZEST, the woody thick skin, quartering the kernel of a walnut; prescribed by some physicians, when dried and taken with white-wine, as a remedy against the gravel.

ZEST is also used for a chip of orange or lemon-peel; such as is usually squeezed into ale, wine, &c. to give it a flavour: or the fine ethereal oil which spurts out of that peel on squeezing it.

ZETETIC METHOD, in mathematics, the method made use of to investigate or solve a problem.

ZEUGMA, a figure in grammar, whereby an adjective or verb which agrees with a nearer word, is also, by way of supplement, referred to another more remote.

ZIBETHICUS, the civet-cat, in zoology, the grey meles, with uniform claws. It was long before the form of this creature, to whom we owe the civet, was known: and long after this before it could be determined to what genus of quadrupeds it belonged: it was first supposed of the cat, and afterwards of the dog-kind; but it is truly one of the badger species. It is a large and fierce animal; its size is that of the common badger, but its body is not so bulky; the head is large, oblong, and considerably thick; the fore-head is depressed; the snout is rounded and thick; the nose turns up a little; the mouth is wide, and is furnished in a very formidable manner with teeth; and there are a few rigid but very long whiskers about it; the eyes are small, the ears large, obtuse, and patulous; the neck is long, rigid, and thick; the tail long, and resembling that of the common cat; it is covered with hair, and there runs a ridge of the same hair all along the top of the back. The whole animal is of a light silvery colour, variegated in a beautiful manner with large spots of black; the legs are very robust, almost entirely black; the feet are armed with very long and sharp claws; under the tail is situated the bag, in which is contained the perfume we call civet; and its situation is the same with that which contains the white sebaceous matter in the badger.

ZIBETHUM, *Civet*. See **CIVET**.

ZIMENT-WATER, or copper water, in natural history, the name by which some have called water found in places where there are copper-mines, and lightly impregnated with particles of that metal. See **COPPER**.

The most famous spring of this kind is a mile distant from Newfol, in Hungary, in a great copper-mine, where the water is found at different depths, and is received into different basons, for the purpose of separating the copper from it. In some of these it is much more highly saturated with this metal than in others, and will make the supposed change of iron into that metal much sooner. The most common pieces of iron used in the experiments, are horse-shoes, nails, and the like; they are found very little altered in shape after the operation, except that their surfaces are more raised. The water which performs this wonderful operation appears greenish in the basons where it stands; but if a glass of it be taken up, it looks clear as crystal; it has no smell, but has a very strong vitriolic and astringent taste, insomuch that the lips and tongue are blistered and scorched on tasting it. The miners use this water as a medicine; and whatever sickness they are seized with, they first attempt its cure with large doses of this water, which usually both vomits and purges them briskly; they also use it in disorders of the eyes. The copper produced from these waters is valued by the people much beyond any other copper, as being more ductile, and running easier in the fire. And from the several experiments made upon the water, the true nature of it may be easily understood. It contains a large quantity of the vitriol of copper, which it probably owes to a solution of that metal, by means of the acid of the common pyrites and water. When this is known, the effects are not difficult to be accounted for; there being no real change of one metal into another, but the true state of the case being that the particles of one metal are dissolved and carried away, and those of another metal deposited in their place; a water thus impregnated is a menstruum capable of dissolving iron, and in the solution of that metal becomes so weakened as to let go the copper it before contained in small parcels.

ZINK, **ZINC**, or **ZINCK**, in natural history, the name of a very remarkable fossil substance, resembling bismuth in appearance, but of a bluer colour. See the article **BISMUTH**.

It is a very remarkable mineral, and one that has never been well understood as to its origin, till of late; for though the world well knew of a long time both zink and lapis calaminaris, and knew that both of them had the remarkable property of turning copper into brass, which one would think might have given a hint to the discovery of a natural alliance between them; yet have they been ever treated of as two different substances, by the writers on these subjects; and Dr. Lawson was the first who ever publicly declared, and proved, lapis calaminaris to be the ore of zink.

Zink is generally confounded with bismuth, though in reality a very different body; but the regulus of these two minerals having a very great external resemblance, the vulgar have not distinguished them; and hence we hear of many ores of zink in the less accurate writers, all which are truly the ores of bismuth.

The lapis calaminaris is the true and general ore of zink, yet that mineral is not confined to this ore alone, but is mixed in great abundance in its disseminated particles among the matter of the ores of other metals, particularly of lead.

Our artificers have long been acquainted with zink, under the name of spelter; but none of them till of late have ever been able to make any guess as to its origin. We have much zink brought to us from the East-Indies, under the name of tutenag; yet no body ever knew from what, or how it was produced there; and all that was heretofore known of it was, that among that strange mixture of ores which the great mines yield at Gosselaer in Saxony, when they were fused for other metals, a large quantity of zink was produced; but Dr. Lawson observing, that the flowers of zink and of lapis calaminaris were the same, and that their effects on copper were the same, never ceased his inquiries till he found out the method of separating zink from it.

The pure zink is a solid metal-like body, of a bluish white, and somewhat less brittle than bismuth, especially when gently heated, and most, of all the metallic minerals, approaches to malleability: it melts in a very small fire, and in a strong one takes fire, burning with a bluish green flame, and subliming into white flowers, which are with difficulty reducible again into the form of zink: in an open fierce fire, it wholly flies off in vapour.

There is great reason to believe, that all the zink or tutenag brought from the East-Indies, is procured from calamine; and we have now on foot at home, a work established by the discoverer of this ore, which will probably make it very soon unnecessary to bring any zink into England, as we have great plenty of the calamine.

The manner of extracting zink from the lapis calaminaris, is this: the lapis calaminaris must be finely pulverized, and well mixed with an eighth part of charcoal-dust, and put into a close retort to prevent the access of air, which would inflame the zink as it rises. The retort is to be placed on a violent fire, sufficient to melt copper. After some time the zink rises, and appears in the form of metallic drops within the neck of the retort. When the vessel is cool, it must be taken out, by breaking off the neck of the retort.

Flowers of ZINK. The flowers of zink are a substance famous in the writings of the chemists, who have led their followers into a thousand errors by the names by which they have called them.

The most simple and easy way of obtaining the flowers of zink pure and white, is this: melt the zink in a tall crucible inclined in the furnace in an angle of 45 degrees, or thereabouts; let the fire be moderate, little stronger than would be necessary for the melting of lead. If the zink is left in this state without being stirred, it forms a grey crust upon its surface, and becomes calcined by degrees under it into a granulose white substance; but to have the flowers, the matter must be stirred from time to time with an iron rod, and this crust broken as often as

it arises; there will then, after some time, appear a bright white flame; and about two inches above it there will be found a very thick smoke, and with this there will arise a quantity of very white flowers, which will fix themselves to the sides of the crucible in the form of fine cotton.

The fumes of zink have a strong smell of garlic, and are very noxious to the lungs. The reducing zink into these flowers, is the destroying it absolutely as to its metallic form; for none of the methods used by chemists to bring back metals to their original state, are able to bring these flowers to zink again.

ZOCCO, ZOCCOLO, ZOCCLE, or SOCLE, in architecture, a kind of stand or pedestal, being a low square piece, or member, serving to support a busto, statue, or the like thing that needs to be raised.

ZODIAC, *Zodiacus*, in astronomy, a fascia or broad circle, whose middle is the ecliptic, and its extremes two circles, parallel thereto, at such a distance from it, as to bound or comprehend the excursions of the sun and planets.

The sun never deviates from the middle of the zodiac, i. e. from the ecliptic, but the planets all do more or less. Their greatest deviations, called latitudes, are the measure of the breadth of the zodiac, which is broader or narrower, as the greatest latitude of the planets is made more or less; accordingly, some make it sixteen, some eighteen, and some twenty degrees broad.

The zodiac, cutting the equator obliquely, makes an angle therewith of $23^{\circ} 29'$, which is what we call the obliquity of the zodiac, and is the sun's greatest declination.

The zodiac is divided into twelve portions, called signs, and those divisions or signs are denominated from the constellations which anciently possessed each part; but the zodiac being immovable, and the stars having a motion from west to east, those constellations no longer correspond to their proper signs, whence arises what we call the precession of the equinoxes.

When a star therefore is said to be in such a sign of the zodiac, it is not to be understood of that sign or constellation of the firmament, but only of that twelfth part of the zodiac, or dodecatemory thereof.

Cassini has also observed a track in the heavens, within whose bounds most of the comets, though not all of them, are observed to keep, which for this reason he calls the zodiac of the comets.

This he makes as broad as the other zodiac, and marks it with signs and constellations like that, as Antinous, Pegasus, Andromeda, Taurus, Orion, the lesser Dog, Hydra, the Centaur, Scorpion, and Sagittary.

ZONE, *ζώνη*, in geography and astronomy, a division of the terraqueous globe, with respect to the different degrees of heat found in the different parts thereof.

A zone is the fifth part of the surface of the earth, contained between two parallels.

The zones are denominated torrid, frigid, and temperate.

The torrid zone is a fascia, or band surrounding the terraqueous globe, and terminated by the two tropics. Its breadth is $46^{\circ} 58'$.

The equator, running through the middle of it, divides it into two equal parts, each containing $23^{\circ} 29'$. The ancients imagined the torrid zone uninhabitable.

The temperate zones are two fasciæ, or bands, environing the globe, and contained between the tropics and the polar circles: the breadth of each is $43^{\circ} 2'$.

The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle: the breadth of each is $46^{\circ} 58'$.

ZOOLOGY, *ζωολογία*, the science of animals. Arctedi observes, that this makes one of the three kingdoms, as they are called, of natural history; the vegetable and the mineral being the two others: in these, however, there is this difference made by writers, that while vegetables and minerals are treated of together, as all of a piece in each, the subjects of zoology are divided; and it is made to compose, as it were, several kingdoms.

Whoever is to write on plants or minerals, calls his work a treatise of botany or mineralogy; and we have no words to express any subdivision of them into kingdoms; but, in zoology, we treat, as different subjects, the different parts of it; and the history of birds is separated, by some, from the rest, under the name of ornithology; that of quadrupeds, under the name of tetrapodology; and we have for the rest, the words entomology, amphibiology, and the like, expressing these things, which are properly but the parts of zoology, as so many distinct and separate studies.

ZOOPHORIC, or ZOOPHORIC COLUMN, is a statuary column, or a column that bears and supports the figure of an animal.

ZOOPHORUS, or ZOPHORUS, in the ancient architecture, the same with frieze in the modern.

ZOOPHYTON, or ZOOPHITE, in natural history, a kind of intermediate body, partaking both of the nature of a sensitive and a vegetable. See the article SENSITIVE Plant.

ZOOTOMY, the art of dissecting animals, or living creatures, being the same with anatomy, or rather comparative anatomy.

ZOPISSA, naval pitch, a kind of mixture of pitch and tar, scraped off ships that have been a long time at sea.

This matter, by being gradually penetrated by the salt of the sea, becomes partaker of its qualities, and being applied to the body externally, is found to be resolute and desiccative.

ZOSTERA, in botany, a genus of plants, whose flower hath no corolla; the cup consists of a plane linear spadix, and contains a great number of very short filaments, topped with ovato-oblong antheræ; the pericarpium is membranaceous, and contains an ovate seed.

ZUINGLIANS, a branch of the ancient Christian reformers, or protestants, so called from their author Huldric Zuinglius, a divine of Switzerland: who, soon after Luther had declared against the church of Rome, and being then minister of the church at Zurich, fell in with him, and preached openly against indulgences, the mass, the celibacy of the clergy, &c.

ZYGÆNA, the ballance-fish, in ichthyology, a species of squalus, with a very broad, transverse, hammer-like head.

This is one of the most extraordinary fish in the world; in its form, the general size is five or six feet, but it grows to be much larger. The head is the most extraordinary figure of that of any fish; it is not oblong, and running in a line with that of the body, but is placed transversely, and has the appearance of the head of a hammer fastened to its handle; the eyes are large, and placed at the two extremities; the mouth is transverse, cut on the lower part of the head, and furnished with three or four rows of sharp teeth; the nostrils are small, and not very conspicuous, and the foramina at the eyes are oblong and large; the body is oblong and moderately thick; there are two back fins, and a pinna ani; the apertures of the gills are ten oblong slits, five on each side, running from just below the head towards the roots of the pectoral fins; the tail is divided into two parts, and the upper of these is much longer than the under.

ZYGOMA, in anatomy, a bone of the head, otherwise called os jugale, being no single bone, but an union or assemblage of two processes, or eminences of bones; the one from the os temporis, the other from the os malæ; these processes are hence termed the zygomatic processes, and the future that joins them together, is denominated the zygomatic future.

ZYGOMATICUS, in anatomy, a muscle of the head, arising from the os zygoma, whence its name, and terminating at the angle of the lips. This muscle, though usually single, is sometimes double throughout; at other times it has a double head; sometimes its tail only is bifid, and it is variously interwoven with the adjoining ones. See the preceding article.

ZYGOPHYLLUM, bean-capers, in botany, a genus of plants, the corolla whereof is composed of five petals.

petals, broadest at the top, obtuse, emarginated, and larger than the cup; the nectarium consists of ten convergent leaves, and includes the germen: the fruit is an oval pentagonal capsule, formed of five valves, containing five cells, with septa adhering to the valves: the seeds are numerous, roundish, and compressed: the figure of the fruit is subject to variation, and there is a species in which the parts of fructification are a fifth less.

ZYMOLOGY, in chemistry, is a term used by some writers, to express a treatise on fermentation, or the doctrine of fermentation in general.

ZYMOSIMETER, an instrument proposed by Swammerdam, wherewith to measure the degree of fermentation occasioned by the mixture of different matters, and the degree of heat which those matters acquire in fermenting; as also the heat or temperament of the blood of animals.

ZYTHOGALA, beer posset, a drink recommended by Sydenham, as good to be taken after a vomit, for allaying the acrimonious and disagreeable taste the vomit has occasioned, as well as to prevent gripes.

ADDENDA ET CORRIGENDA.

ASTER, starwort, a genus of plants producing a radiated flower, the disk of which is composed of several funnel shaped hermaphrodite floscules, which spread open at the top in five parts, and contain five capillary filaments, topped with cylindrical antheræ, with an oblong germen supporting a filiform style.

ATRIPLEX, orach, the name of a plant common in the hedges, esteemed cooling and emollient, and its seeds, given internally, diuretic, and good in disorders of the uterus.

In the article **ATMOSPHERE**, for 29 inches, read 29½ inches; and for 3980 pounds troy, read 31320 pounds.

AURICULA, bear's ear, the name of a very curious genus of flowers, of which there are several species.

Auriculas are propagated either by sowing their seeds, or planting their off-sets. In order therefore to obtain good flowers from seeds, choice must be made of the best flowers, which should be exposed to the open air, that they may enjoy the benefit of showers, which is necessary to their producing good seeds. The time for sowing those seeds is from August to Christmas; and the best soil for sowing them in, is good fresh earth from a common, rather light, mixed with rotten dung and leaves, previously prepared. With this compost, the pots or tubs, in which the seeds are intended to be sown, should be filled. After leveling the surface very smooth, sow the seeds thereon, and cover them very lightly with rotten mellow mould, taken out of the stems of decayed and hollow willow trees. The boxes or tubs should be situated where they can only receive the morning sun. In the following spring the young plants will come up, when they must be frequently refreshed with water in dry weather till July, when they will be large enough to transplant; at which time, with the above preparation of earth, plant them in beds or boxes about three inches asunder, shading them from the sun in hot weather. After flowering, those which appear to be valuable, should be taken up and transplanted into pots of the smallest size; for if the pots are large, they will not thrive so well.

The method of propagating the auricula from slips or off-sets is this: The slips should be taken off in April when the old plants are in bloom, and planted in small pots, in the same sort of earth as before directed, and, during the summer season, placed in a shady situation, and frequently refreshed with water; but protected from the violent rains which fall in the autumn; and in winter very little wet should fall on them, nothing being more prejudicial to auriculas in winter than wet. Nor should they be too much exposed to the sun in the spring, which is apt to forward their flowering too soon, by which means the frosts in March will damage them, unless carefully protected.

DANIEL, the name of a canonical book of the Old Testament, written by a prophet of the same name, descended from the royal house of the kings of Judah, and contemporary with Ezekiel. The style of Daniel is not so lofty and figurative as that of the other prophets: it is clear and concise, and his narrations and descriptions

simple and natural. His prophecies concerning the coming of the Messiah, and the other great events of after-times, are so clear and explicit, that Porphyry objected to them, saying, they must have been written after the facts were done.

ERYGERON, groundsel, a genus of plants, with a compound flower, composed of many hermaphrodite florets, which form the disk, and female half-florets, which make the rays, contained in one oblong scaly empalement. The hermaphrodite florets are funnel-shaped, have five stamina, and a small germ crowned with long down sitting on a naked receptacle.

GLECHOMA, ground-ivy, gill go by the ground, alehoof, or turnhoof; the name of a well known creeping plant, common in hedges and shady places. It is supposed to be particularly serviceable in disorders of the breast, for cleansing and healing ulcerations in general, resolving coagulated juices, and purifying the blood.

GELDER ROSE, or **GUELDER ROSE**. See **VIBURNUM**.

HONEYSUCKLE. See the article **LONICERA**.

HOLYHOCK, *Alcea*, or *Vervain mallow*, see the article **ALCEA**.

HORNBEAM. See the article **CARPINUS**.

HORSEMANSHIP, the art of riding, breaking, disciplining, and managing horses.

Horsemanship, in its greatest latitude, includes what relates to the knowledge of the make, colour, age, temper, and qualities of horses; their respective countries and climates; with the manner of breeding, propagating, and discovering the uses or services they are most proper for; whether the wars, the race, the saddle, or labour.

But the word is more peculiarly understood of the art of riding; or of directing a horse to advantage, not only in the ordinary motions, but more especially in the managing, or making him work upon voltes, airs, &c.

HYOSCIAMUS, henbane, the name of a plant with soft, hairy, oblong, notched leaves; and bell-shaped flowers, cut into four segments, followed by irregular cup-like capsules, whose cover falling off discloses numerous small seeds in two cells.

There are two species of henbane, distinguished by the epithets of white and black. They are both strongly narcotic and deleterious; so that they are used only in external applications, in which manner a cataplasm of the leaves is said to be refrigerant and discutient.

KIDNEY-BEAN, or **FRENCH BEAN**, *Phaseolus*, in botany, a genus of plants, producing papilionaceous flowers; the vexillum is cordate, obtuse, emarginated, and reclined, with reflexed sides; the alæ are ovate, the same length as the vexillum, and stand upon long ungues; the carina is narrow, and revolves spirally, in a contrary direction to the sun; the filaments are ten in number, nine of which are carinated and spiral, and topped with simple antheræ: the fruit is a long, straight, coriaceous legumen, ending in an obtuse point, containing oblong, compressed, kidney-shaped seeds.

ADDENDA ET CORRIGENDA.

There are several kinds of kidney-beans cultivated for culinary purposes; as the liver-coloured bean, the Battersea-bean, the Canterbury dwarf-bean, the speckled dwarf-bean, and those which require support; such as the white and scarlet blossomed beans, &c.

French-beans are propagated from the seeds, and are generally planted in rows, at about three inches asunder, and about an inch deep, excepting the larger sorts, which should have a greater distance. The first season for sowing them is about the latter end of April, and the last in July; but there should be intermediate sowings in May and June, to continue the supply of the table, as they will not last above three weeks in gathering, particularly in hot dry weather.

The use of kidney beans (or rather the pods) as a food, is so well known, as to be quite unnecessary to mention it; they are opening, emollient, resolvent, and promote urine, and they generally agree with most constitutions; the meal of the seed is sometimes mixed in emollient cataplasms.

LABURNUM, base tree trefoil, the name of a genus of plants, of which there are several species. It hath a butterfly flower. The standard of the flower is arising, oval, and reflexed on the sides. The wings are obtuse, erect, and the length of the standard. The heel is bellied and acute. It hath ten stamina, nine joined and one standing separate, and an oblong germen, which afterward becomes an oblong blunt pod, filled with kidney-shaped flat seeds.

LUNARIA, moon-wort, in botany, a genus of plants whose flower is tetrapetalous and cruciform; it hath six stamina, two of which are shorter than the rest; the fruit is a large, erect, plane, compressed, elliptical pod, opening with two valves, and containing two cells, which inclose a few compressed kidney-shaped seeds.

MANDRAKE, *Mandragora*, in botany, a genus of plants, whose flower hath one erect, bell-shaped petal, which is a little larger than the empalement. It has five awl-shaped stamina, which are arched and hairy at their base. In the center is situated a roundish germen, which afterwards turns to a large round berry with two cells, having on each side a fleshy convex receptacle, filled with kidney-shaped seeds.

OROBANCHE, broom rape, in botany, a genus of plants, the corolla of which is monopetalous and ringent; and its fruit an oblong capsule formed of two valves, and containing a great many minute seeds.

PEA, *Pisum*, in botany, the name of a well known genus of plants, many sorts of which are cultivated in gardens, and some in the open fields. They are generally sown in rows, at about three feet asunder, and four or five inches distant between the peas in each row. When the plants are come up, the earth should be drawn up to their shanks with a hoe, and the ground kept entirely free from weeds: and when they are grown eight or ten inches high, some brush-wood should be stuck into the ground close to the peas, for them to ramp upon, which will support them, and hinder their trailing upon the ground, whereby many of the larger sorts rot in wet seasons. Besides, by thus supporting them, the air finds a free passage between them, which will preserve the blossoms from falling off before their time, and occasion them to bear much better, than if permitted to lie upon the ground. There will also, by this means, be room sufficient to pass between the rows to gather the peas when they are ripe.

PINGUICULA, butterwort, in botany, a genus of plants, whose flower is monopetalous and ringent, the longer lip of which is strait, obtuse, bifid and supine; the shorter lip is bifid, more obtuse and spreading: it hath

a corniculated nectarium, produced from the base of the petal: the stamina are only two cylindric curved filaments, topped with roundish antheræ; and the fruit is an oval capsule compressed at the top, having one cell, which contains many cylindrical seeds, with a loose receptacle.

PLATINA, a metal found in the gold mines in the West-Indies, but lately known in Europe.

It is brought over in small white grains mixed with a ferrugineous sand, and some other foreign matters. The Spaniards gave it the name of Platina, a diminutive of Plata, silver, probably from its colour; for in this respect it greatly resembles silver, though in others it comes nearer to gold.

It possesses, in effect, almost all those properties which have been hitherto supposed characteristic of gold, and stands all the tests by which that metal has been usually assayed or refined; being nearly as ponderous; equally dissoluble in aqua regia, and precipitable by the other metals which dissolve in that menstruum: equally resisting aqua fortis, and the other simple acids, as well as the regal cement; being equally permanent and fixed in the fire; equally indistinctible by lead and bismuth; unaffected by nitre and by sulphur; incapable of being scorified by the sulphureous part of antimony, or volatilized by its reguline.

This metal is in some degree malleable; but less so when ignited than when cold. Its specific gravity is to that of gold nearly as 18 to 19.

PULEGIUM, pennyroyal, the name of a plant of the mint kind, differing from the mints strictly so called, in the flowers being disposed, not in spikes on the tops, but in thick clusters, at distances, round the joints of the stalks; and the upper segment of the flower not being nipped at the extremity.

Pennyroyal is a warm pungent herb, a good carminative and deobstruent in hysteric cases, and disorders of the breast.

PYROMETER, in mechanics, a machine for measuring the degree of expansion of metals by heat.

The word is formed from the Greek, *πῦρ*, fire, and *μετρεω*, to measure.

There are several kinds of pyrometers, invented by different authors; but the best we can remember to have seen, is described by Mr. Ferguson in his Supplement to his Lectures.

QUAIL, the name of a well known bird of passage, frequenting the corn-fields, and sometimes the meadows. They begin to sing in the month of April, and make their nests in May, building on the ground.

RATSBANE, the vulgar name for arsenic. See **ARSENIC**.

RIBES, the currant bush. See the article **CURRENT**.

ROCKET, in botany, the English name for a beautiful species of hesperis: it is a biennial plant, and increased by cuttings in the summer. It requires a strong soil, and flowers in June: that with double flowers is most regarded.

RUSCUS, butchers-broom, or knee-holly, the name of a well known plant, common in the woods of various parts of England.

SNIFE, in ornithology, the name of a bird having four brown streaks on the back. It is a small and beautiful bird, its flesh delicate, and much esteemed at table.

SPARTIUM, Spanish broom, in botany, the name of a genus of plants whose flower is pentapetalous and papilionaceous; and its fruit a long cylindrical obtuse pod, with one cell and two valves, which include a number of round kidney-shaped seeds.

TUTSAN, *Androsæmum*, in botany, the English name for a species of the hypericum. See **HYPERICUM**.

✻ The Authors and Proprietors of the COMPLETE DICTIONARY of ARTS and SCIENCES, to testify their gratitude for the uncommon success their work has met with from the Public, take this opportunity of declaring, that as improvements are continually making in many parts of the Arts and Sciences, they will be careful to collect whatever seems worthy of being preserved, and print them separately for the benefit of the purchasers of this edition.
